Partial aeration of strong sewage with activated sludge. WILLIAM D. HATFIELD. *Ind. Eng. Chem.* 20, 832-5(1928).—The sewage treatment plant at Decatur, Ill., consisting of Imhoff tanks, sprinkling filters and appurtenances, became heavily overloaded because of the rather phenomenal growth, after the war, of a corn-products manufg. company. The sewage became about 5 times as strong as normal city sewage. An expt. station to study partial aeration as a method of increasing the capacity of the existing plant and to reduce the odor hazard was operated for 15 months. Complete operating and chem. data are given which indicate that the process could be used to triple the capacity of the filters. A new addn. to the sewage plant has now been completed on the basis of the data presented and is in operation. This method, which has been termed pre-aeration, seems particularly adapted to increasing the capacity of sprinkling filters, but should also prove valuable as a method of partial treatment where complete treatment is not advisable until later. C. R. FELLERS

Accuracy of stream-flow measurements. KENDALL K. HOYT. *Eng. News-Record* 101, 167-8(1928).—Data are given which show that the Price current meter, when employed by experienced personnel, gives consistent results under different channel conditions, and that it checks with the much-praised Gibson method. R. E. T.

A stream-flow sewage treatment process. HARRY N. JENKS AND MAX LEVINE. Iowa State College. *Eng. News-Record* 100, 808-13(1928).—A distinctly new means of aeration, designated as stream-flow aeration, has been originated and studied. When embodied in a sewage works of special design, the functional action simulates, more closely than any existing method, the basic phenomena responsible for natural self-purification of streams. The structural features of a stream flow plant, with the exception of the aeration units, conform in essential particulars to the general design employed in activated-sludge plants. The aeration units consist essentially of a biochem. oxidation zone contained in a tank or basin through which the main body of sewage passes, and a sep. re-aeration or O₂-absorbing zone, embodied in a paved surface adjacent to or above the tank, over which an independent and concomitant recirculation of the org. wastes is maintained in a layer $\frac{1}{2}$ to 1 in. in depth. The sewage is with drawn from the oxidation zone, discharged on to the re-aeration surface and allowed to flow down the slope on this surface (in which is placed transverse cleats to induce riffing), thence returning to the oxidation zone within the aeration tank. It is estd. that a strong domestic sewage having a biochem. O demand of 350 p. p. m. should be successfully treated by 6 hrs. stream flow aeration of 50 times the vol. of flow, on which basis the energy required should not exceed 12 h. p. per million gal. treated. Expts. indicated that the re-aeration surfaces should be from 6 to 10 ft. in length, providing 3-5 sec. exposure of the sewage film to the atm. each time the sewage flows over the pavement. The results obtained in the treatment of milk wastes in a lab. exptl. plant and packing wastes in a field exptl. plant are given. Expts. were made also on the division of the treatment process into 2 or more stages, by developing and maintaining means when treating 2^d milk wastes in stream-flow aeration units. Previous expts. had shown that it was impossible to produce nitrates in single stage treatment of these wastes by the activated-sludge process. An important observation made was the great advantage of removing as quickly as possible all excess sludge with its high O₂-demanding characteristics. R. E. THOMPSON

Automatic hydro-electric control at Baltimore sewage works. C. E. KEEFER. *Eng. News-Record* 100, 926-7(1928).—When the Baltimore sewage works were constructed the flow line of the final settling tanks was put 20.5 ft. above the Black River, into which the effluent is discharged, to provide sufficient head for intermittent sand filters to be installed later if required. The filters were found unnecessary and the head has been employed for power generation. Installation of automatic control equipment at the power plant has reduced the operating personnel from 7 to 1 and the cost of power from 3.7 to 1.21¢ per kw-hr. The sewage flow is 50-60 million gals. per day. R. E. THOMPSON

Sewage-works construction at Cleveland, Ohio. A. A. BURGER. *Eng. News-Record* 101, 53-8(1928).—The southerly sewage works, the last of 3 constructed by the city, consists of an overflow chamber, screen building, 4 grit chambers with mechanical grit-removal equipment, a battery of 24 Imhoff tanks, 3 twin dosing tanks and 6 acres of trickling filters, and 3 humus tanks with continuous sludge removal equipment. Glass-covered sludge-drying beds, 94,000 sq. ft. in area, are to be constructed. The works will treat the sewage of 400,000 people, and is designed for future extension. R. E. THOMPSON

Sewage agitation and chlorination tests at Havre, Mont. EMIL SANDQUIST AND H. B. FOOTB. *Eng. News-Record* 100, 1001-2(1928).—The sewage flow of Havre,

0.587 million gal. per day, is discharged untreated into the Milk River at 3 points. The river flow is equal to or in excess of 7 sec.-ft. per 1000 population for 75% of the year. Expts. have been carried out on treatment by agitation to break up the solids and chlorination. Agitation was effected with a propeller driven at 500 r. p. m., and Cl_2 dosage was varied to maintain residual of 0.5–1.0 p. p. m. after 10 min. contact. The dosage ranged from 10 to 21 p. p. m., varying with flow and H_2S content. The bacterial count was reduced to 100–1200 per cc and *B. coli* tests on 10-cc. portions were negative. Hydrogen sulfide was reduced 26.5% by agitation alone, and 63% by agitation and chlorination. The cost of such treatment for the 4 months of low stream flow would total \$1320 per year.

R. E. THOMPSON

The sewer and clarification plant of the Rath rolling mills of the Mannemann tube works in Düsseldorf. OTTO MOHR. *Warme & Kälte Tech.* 28, 188 9(1926).—All water is used in a closed circuit, on account of the distance from the supply. Water from sanitary equipment is settled and aerated; that from industrial equipment is settled and skimmed.

ERNEST W. THIELE

The hygienic importance of the permeability of window glass to ultra-violet light. K. B. EISENBERG. *Gesundh. Ing.* 51, 465–7(1928).—Ultra-violet light is capable of activating org. substances. A table is given showing the per cent permeability for light of various wave lengths (320μ to 290μ) of various kinds of glass. All glass shows a rapid decrease in the per cent permeability with decreasing wave length but ordinary window glass is the poorest of all. At 320μ its permeability is about 1% and at 290μ the permeability has dropped to a negligible value. Only the direct light rays contain ultra-violet light; reflected rays have lost most of the shorter light rays. Also the amt. of ultra-violet light varies with the hour of day, time of year and the relative position of the house. In order to get much ultra-violet light into a house, it is necessary to use one of the several special glasses made for this purpose, such as silica glass, ultra-violet glass, etc.

WAYNE L. DENMAN

Impurities in the atmosphere. A. J. H. KAM. *Chem. Weekblad* 25, 298–301(1928).—The stack gases have been examd. in various types of factories. Among the more poisonous substances, the analysis detected H_2S , F, SO_2 , SO_3 , HCl, As and AsH_3 .

A. L. HENNE

Chemical examination of irrigation waters and alkali soils (HIBBARD) 15. Fumigation with $\text{Ca}(\text{CN})_2$ dust (QUAYLE) 15. Apparatus for the micro-determination of dissolved oxygen (THOMPSON, MILLER) 1. Brass in engineering (JONES) 9. Some combustion problems in their relation to public health (PARR) 21. Radioactivity of some mineral waters and of the drinking water of the Somes and Cris valleys (DIMA) 3.

GARTNER, AUGUST: *Die Wasserversorgung und Abwasserbeseitigung im rheinisch-westfälischen Industriegebiet*. München: R. Oldenbourg. 23 pp. M. 3.60.

Apparatus for softening water with base-exchange materials. UNITED WATER SOFTENERS, LTD., AND E. B. HIGGINS. Brit. 281,416, Sept. 15, 1926.

Apparatus for softening water with zeolites. WALTER H. GREEN (to General Zeolite Co.). U. S. 1,677,891, July 24.

Preventing incrustation in boilers. SOC. ANON. SUBOX. Brit. 281,598, Dec. 4, 1926. Resin "in the hydrated state" such as is obtained by treating colophony in the presence of a solvent with an alk. substance and then with an acid substance is used, with or without other substances such as a gum, tannin or dextrin.

Preventing and removing incrustation in boilers. J. BILLWILLER. Brit. 281,361, Aug. 25, 1926. See Can. 281,216 (C. A. 22, 3010).

Cleaning boilers. WILHELM BAUMANN and HEINRICH BAUMANN. Fr. 632,695, April 12, 1927. A small quantity of org. compds. such as quinaldine or acridine is added to the acid solns. used for cleaning boilers, etc.

System for heating, deaerating and evaporating water. GEORGE H. GIBSON (to Cochrane Corp.). U. S. 1,677,890, July 24. App. is described suitable for use in prep. boiler-feed water from condenser condensate and raw make-up water with steam at high and low pressures.

Sewage digestion tank and sludge circulating pump and pipe system connected with or within the tank. M. PRÜSS. Brit. 281,541, May 23, 1927.

Utilizing domestic refuse, etc. MUSAG GES. FÜR DEN BAU VON MULL-UND SCHLACKEN-VERTUNGSANLAGEN A.-G. AND A. GROTE. Brit. 280,902, Nov. 20, 1926. Domestic

or industrial refuse of "gutter refuse" is passed through an inclined rotary furnace in the first portion of which combustible constituents are burnt out and in the remaining part of which the residue is fused and formed into a slag in granular or lump condition.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

The hot fermentation of stable manure according to H. Krantz. HANS GLATHE *Landw. Vers. Sta.* 107, 65-129(1927).—The hot fermentation of stable manure makes possible, in addn. to an essential limiting of the losses during storage, a better utilization of the nutritive materials of the manure, especially the N. Hitherto a nearly complete preservation and utilization of the nutritive materials contained in stable manure was attained only by the preservation of the manure in deep stalls. In comparison herewith the hot fermentation process shows different advantages especially of a hygienic nature: (1) the slight possibility of the transfer of diseases, especially mastitis-producers in the stall itself; (2) the far-reaching destruction of the producers of the foot and mouth disease, as well as all non-spore-forming pathogenic bacteria by the action of temps. between 50° and 60° for several days. E. F. SNYDER

Investigations on the form and structure of soil particles. G. I. POKROVSKII *Kolloid Z.* 158-61(1928).—The important phases of the method used are described. The investigated soils were built up of particles of 2 sizes. The particles of these 2 sizes correspond to both maxima on the curve given. The interval between these maxima is on the other hand filled with conglomerates of small particles. These complicated forms are on account of their structure opalescent, which the positive value β signifies. E. F. SNYDER

Colloidal soil material. P. L. GILE. *Soil Science* 25, 359-64(1928).—The colloidal soil material might be simply and logically defined as "that material in the soil which has an appreciable capacity for adsorption or for evolution of heat on wetting." Such a definition is inadequate for distinguishing between colloid and non-colloid in a mixt. of these 2 classes of material, since soil materials cannot be sepd. according to their adsorptive or heat of wetting capacities. The colloidal soil material has also been defined as including: all soil org. matter, inorg. material dispersible into particles less than 1μ in diam. by a treatment that does not disintegrate distinctively mineral particles, and any undispersed material which microscopical observation shows is made up of particles less than 1μ in diam. A definition of this kind is practicable, since methods are available for sepg. or distinguishing soil constituents according to the characteristics specified; namely, chem. compn. of the material and size and structure of particles. It is somewhat questionable whether fibrous org. matter and Fe concretions should be classed as colloid and whether the upper limit for the size of colloidal soil particles should be placed as 1μ or higher. E. F. SNYDER

Variations of the colloidal material in typical areas of Leonardtown silt loam soil. R. S. HOLMES. *J. Agr. Res.* 36, 459-70(1928).—The constancy of the chem. compn. and certain phys. properties of the colloid of Leonardtown silt loam soil was studied. The samples investigated were typical of the Leonardtown series, taken from different localities. The colloid was found to vary little in SiO_2 , Al_2O_3 , Fe_2O_3 , K_2O , MgO and combined H_2O . Other constituents (MnO , CaO , Na_2O , P_2O_5 and SO_3) varied more widely. The p_H , adsorptive capacity for water vapor, for NH_3 and for Ba from BaCl_2 soln. were all fairly const. Leonardtown soil may be regarded as characterized by its adsorptive properties and by those inorg. constituents which are present in appreciable quantities. The probable error of sampling indicates that 8 to 10 samples of a soil should be sufficient to show with considerable accuracy the kind of colloidal material characteristic of the type. The hardness of the B_2 horizon of the Leonardtown soil type is not primarily dependent upon the kind or quantity of colloidal material present. M. S. ANDERSON

The clayey colloids and soil solutions. A. DEMOLON, H. BURGEVIN and G. BARBIER. *Compt. rend.* 186, 1646-9(1928); cf. *C. A.* 22, 3081.—The results verify the theoretical conclusions deduced from the Freundlich formula. They show the importance there is in maintaining clayey soils satd. with Ca, from the point of view of the mobility of the cations energetically fixed by the clay. The present study also shows that one cannot in these soils consider the total exchangeable K as capable of always contributing the same efficacy to plant nutrition. The necessity of considering in this regard the content of the absorption complex explains in particular the inefficacy often

noted in a similar case with small amts. of K fertilizer when the large amts. give positive results. The same conclusions apply wholly to NH_4 if nitrification does not permit the rapid renewal of the quantities passing in soln. When nitrification is retarded there results, in clayey soils and for small amts. of ammoniacal fertilizers, an amt. of N in the soil solns. insufficient for obtaining max. yields. There also results a decrease of ammoniacal N with respect to the essentially mobile HNO_3 . E. F. SNYDER

Investigation of the properties of colloidal material in Missouri soils. R. BRADFIELD. Missouri Agr. Expt. Sta., *Bull.* 256, 94-6(1927).—It has been found that with the non-calcareous, non-saline soils studied the electrodialyzable bases were identical with the exchangeable bases detd. by the neutral salt extn. methods. Electrodialysis had several advantages over the neutral salt extn. method. By the use of colloidal clay purified by electrodialysis it has been possible to demonstrate the colloidal acid theory of soil acidity previously developed. Investigations of the satn. capacity of soils, of the effect of the p_H value and of the nature of the exchangeable bases upon the retention of PO_4 by electrodialyzed colloidal clay and on the size distribution of particles in colloidal clay have been made. E. F. SNYDER

The hydrometer method for studying soils. GEORGE J. BOUYOUCOS. *Soil Science* 25, 365-9(1928); cf. *C. A.* 22, 292.—Exptl. refutation of disputed points regarding the hydrometer method. E. F. SNYDER

The crop-producing power of limited quantities of "essential" plant nutrient. CHARLES HARTMAN AND WILBUR L. POWERS. *Soil Science* 25, 371-7(1928).—The results seem to indicate the optimum concn. needed during the earlier stages of growth and also the crop-producing power of each mg of so-called "essential" element, for the conditions of the expt. NO_3^- effected by far the highest yield of dry matter per mg. while the formation of dry matter per mg. Mg^{++} was comparatively low. In another report the concns. needed in the soil soln. for optimum growth are indicated to be at least as high as here suggested in the case of SO_4^{--} and Ca^{++} . E. F. SNYDER

Method for the determination of phosphoric acid in samples of soil. Z. KOEHLER, H. SOWINSKA AND P. TERESZCZENKO. Univ. Krakau *Roczniki Nauk Rolniczych I Lesnych* 15, 424-6; *Chem. Zentr.* 1927, II, 486.—In analyses of the HCl ext. of soils poor in P_2O_5 , the method of Lorentz for the detn. of P_2O_5 (cf. Neubauer and Lucker, *C. A.* 6, 1264) gives far better results than the ordinary Mo method. It was tested with the crude ext. and with $\text{Mg}_3(\text{PO}_4)_2$ and MgNH_4PO_4 . C. C. DAVIS

A brief method for chemical examination of irrigation waters and alkali soils. P. L. HIRSHARD. *Soil Science* 25, 351-5(1928).—A procedure for the detn. of the ions, Ca^{++} , Mg^{++} , SO_4^{--} , CO_3^{++} , HCO_3^- , Cl^- and Na^+ , in ordinary H_2O is described. The H_2O ext. of a soil was analyzed as described for ordinary water and the p_H value, CaCO_3 , NO_3 and PO_4 were also detd. E. F. SNYDER

Manganese as an active base in the soil. C. J. SCHOLLENBERGER. *Soil Science* 25, 357-8(1928).—As a result of previous work from which it was assumed that there might be some connection between the development of active Mn and the change in reaction, several mixtures of soil and calcite were prepd. The only significant change produced by the treatment was a very large increase in exchangeable Mn, together with a decrease in the acid reaction. The data indicate that the increase in percentage of total base-absorbent capacity satisfied by the neutral salt-forming bases is the factor causing the change in reaction. E. F. SNYDER

Soil acidity studies. C. R. RUNK. Delaware Agr. Expt. Sta., *Bull.* 152, 6-7 (1927).—(1) *Acidity of the soils of the State.*—Taken as a whole the soils of the State have a wide range of acidity from neutral to strongly acid. The latter soils are mostly from areas not well suited to crop production, due to drainage and other factors. (2) *Buffer qualities of soils.*—(a) Lab. tests. Some soil types of the State possess strong buffer qualities and large amts. of lime or fertilizer materials may be added without disturbing the physiol. balance of the soil soln. to such an extent as to retard the crop. Other types are very easily thrown out of balance and these soils must be handled carefully. (b) Field tests. Work has been started to learn how the buffer capacity of the soil under field treatments compares with the lab. results. (3) *Reaction and crop growth in the field.*—Very poor stand and growth of alfalfa have been secured on the plots of p_H 6, 8, 7, 3 and 7.8. The best growth and stand of alfalfa have been on the plots between p_H 5.4 and 6.5. (4) *Lime requirement methods.*—One hundred and sixty-five soils have been tested with the Truog, KCNS and Ca acetate methods. The H-ion concn. was also detd. and titration curves were made for buffer capacity. No agreement was found among the methods used. (5) *Effect of continued fertilizer treatments upon reaction.*—Tests in progress. (6) *Chlorosis of soy beans.*—Quite marked results were obtained in the greenhouse in preventing the development of chlorosis by appli-

cation of K salts at planting time and also by side dressings for untreated plants which had begun to develop considerable chlorosis. The side dressed plants developed normally after treatment. The treatments used in this series are being used in the field.

E. F. SNYDER

Notes on the determination of the hydrogen-ion concentration of soils. FELIX G. GUSTAFSON. *Ecology* 9, 360-3 (1928).—Results indicate that it is not a safe practice to filter a soil soln. to free it from suspended particles. Centrifuging clears the soil soln. much better and does not change the p_H of the soln. The H_2O used must not have too much dissolved material in it, and it is always best to use distd. H_2O . For these reasons it is best to make the detns. in the lab. rather than in the field. It is safe to make the detn. of the p_H value of a soil in the lab. some time after the soil has been brought in because the p_H of the soil does not change during a few weeks of storage in the lab.

E. F. SNYDER

Concentration of hydrogen ions in the soil and plant formation in "Dolina Chocholowska" (Tatra). JAN WLODEK and KAZIMIERZ STRZEMIENSKI. Univ. Krakau. *Roczniki Nauk Rolniczych I Lesnych* 15, 321-38, *Chem. Zentr.* 1927, II, 484. - Investigations of the diffusion of plant associations in the Chocholowska Valley showed that this diffusion is far more dependent upon the geologic and ecological conditions than upon the p_H value. On the other hand the diffusion of wild plants, especially horse-tongue and perhaps mycorrhiza as well, depends to a great extent upon the soil reaction.

C. C. DAVIS

Soil microbiology. III. Fixative power of soil. S. WINOGRADSKY and (MME.) J. ZIEMIECKA. *Ann. inst. Pastur* 42, 36-62 (1928); cf. *C. A.* 21, 976. The N fixing power of organisms in the soil can be detd. by (1) the growth obtained from 1 g. of the soil on a plate of selective silica gel medium and (2) the total growth obtained spontaneously in a sample of the soil. The limestone and P_2O_5 requirements are indicated from the samples collected for these tests.

E. W. W.

Food requirements of soil amebae with special reference to their inter-relation with soil bacteria and fungi. L. B. SEVERTZOVA. *Centr. Bakt. Parasitenk., I Abt.* 73, 162-79 (1928).—Some species of bacteria, yeasts and molds are more acceptable as a food for soil amebae; hence they will be chosen first from a mixt. JOHN T. MYERS.

The abo-abo soil of Occidental negros. M. M. ALICANTE. *Philippine J. Sci.* 35, 391-401 (1928). Because of the peculiar phys. characteristic of the surface soil, the rate of evapn. and percolation became high, thus greatly reducing the available H_2O supply in the surface soil for the use of the plant. During the period of low pptn. and high evapn. the available H_2O supply in the surface soil is limited, because of the unusual formation of the lower strata—sandy subsoil and gravel substratum which prevents the capillary transmission of H_2O from below to the surface soil. The porosity of the abo-abo soil is primarily due to the absence of a sufficient amt. of colloidal materials. The different soil organisms concerned in the formation of available plant foods are rendered inactive by the unfavorable reaction of the soil soln. present in abo-abo soil. The limited H_2O supply in the surface soil and the unfavorable soil reaction are the factors responsible for rendering any com. fertilizer application in abo-abo soil ineffective.

E. F. SNYDER

The effect of cyanamide in different soil reactions. BRONISLAW CHROSTOWSKI. Landwirtschaftl. Hochschule, Warschau. *Roczniki Nauk Rolniczych I Lesnych* 15, 481-93 (1926); *Chem. Zentr.* 1927, II, 484. The effect of fertilization with $CaCN_2$ on the N content and on the growth of oats is almost independent of the soil reaction, though in strongly alk. soils ($p_H > 8$) the effect is deleterious.

C. C. DAVIS

Experiments on the fertilization of meadows. E. TRUNINGER. *Landwirtsch. Jahrbch. Schweiz* 40, 783-862; *Chem. Zentr.* 1927, I, 3127. About two thirds of the soils tested proved to be poor in P_2O_5 , and about one-half were poor in K_2O . Fertilization with P_2O_5 alone or with K_2O alone was of advantage only on soils very rich in nutrients and over a period of some yrs., while fertilization with both P_2O_5 and K_2O had a positive result in 80% of the cases. In no case did fertilization with $CaCO_3$ and P_2O_5 - K_2O increase the yield, though it did have a favorable influence on the health of the crops and was a protective against washing away. Fertilization with N should be abandoned because of its expense and its uncertain action. The effect of liquid manure was unsatisfactory, and it must be assisted by P_2O_5 and by CaO on acid soils. The use of artificial fertilizers on meadows must be greatly increased.

C. C. D.

Itano process of composting. I. General description, nature of fermentation and sanitary significance. ARAO ITANO and SATIYO ARAKAWA. *Ber. Ohara Inst. landw. Forsch.* 3, 497-504 (1928).—The Itano process of composting is based upon rapid aerobic fermentation at high temp., a supply of a certain amt. of nitrogenous material in pro-

portion to the cellulose, and the introduction of certain bacteria. The bacteria are thermophilic and must be capable of decomp. cellulose. To encourage oxidation in the process, a special zymotic chamber constructed so as to furnish a max. air supply is used during the fermentation. The temp. rises rapidly the first week. The contents are removed after the temp. drops, the time usually being 3 weeks. Since temps. as high as 75 to 80 are reached, the germicidal action has a marked sanitary significance for the Japanese farmer. The loss of org. matter and volatile N compds. is comparatively low. Any kind of org. waste material may be used. The chem. compn. of composts made from rice straw, barley straw, rice husks and weeds averages: total N 2.00 + K 1.44 and phosphates 0.85%. RUSSELL C. ERB

Fermentation of straw and artificial manure. G. RUSCHMANN. *Z. Spiritusind.* 51, 187(1928).—A method of fermenting straw by addition of "Adco" is discussed. The process has not been completely developed. C. N. FREY

An observed case of "spontaneous" ignition in stable manure. L. H. JAMES, G. L. BIDWELL AND R. S. MCKINNEY. *J. Agr. Research* 36, 481-5(1928).—Temp. observations taken in connection with a case of spontaneous ignition of stable manure are given. When exposed to the air charred straw glowed a fiery red. O aeration of a small section of the heating material produced an increase of 26.5° in 30 min. M. S. ANDERSON

Chemical stimulants and germination of seeds. F. KOTOWSKI. *Proc. Am. Soc. Hort. Sci.* 23, 173 6(1926); *Expt. Sta. Record* 58, 535.—Working at the Univ. of Calif., K found that soaking the seeds of peppers, spinach and parsnips in certain solns. apparently increased the percentage of germination but had no influence on the rapidity of germination. E. g., pepper seeds soaked for 48 hrs. in a 1.5% soln. of $MgCl_2$, $NaNO_3$ and $MnSO_4$ gave in 20 days at a const temp. of 25° 81, 84 and 80% of germination as compared with 78% for seeds soaked in distd. water. The treatment of spinach seeds gave even more striking results. H. G.

Better methods of canning crops production. C. B. SAYRE. N. Y. Agr. Expt. Sta., *Bull.* 553, 1-30(1928).— $(NH_4)_2SO_4$ at a rate of 72 lb. per acre increased tomato yields 2 tons per acre, followed closely by $NaNO_3$. $Ca(NO_3)_2$ barely paid the cost of application; and urea did not produce sufficient increase to return a profit. The soil was of alk. reaction. Early plantings of peas gave much higher yields than later plantings. In general, mercurial seed disinfectants slightly increased the yield of peas but had no appreciable effect on sweet corn. With stringless beans and cabbage, P is an important factor in increasing yields. C. R. FELLERS

The effect of potassium salts on the availability of nitrogen in ammonium sulfate. W. B. MACK AND D. E. HALEY. *Soil Science* 25, 333-6(1928).—Neither Cl nor K compds. consistently inhibited the process of nitrification. In fact, in soils treated with $(NH_4)_2SO_4$ the rate of nitrification was greater at the end of the test for all addns. of either Cl or K compds. Very rapid nitrification during the first 3 weeks was generally followed by a loss of NO_3 during the following 2 weeks. Mixing the soil at the end of 7 weeks resulted on the whole in increasing the rate of nitrification. Interchange of ions, $NaCl + KNO_3$ and $NH_4Cl + K_2SO_4$ instead of $NaNO_3 + KCl$ and $(NH_4)_2SO_4 + KCl$, resp., decreased the rate of nitrification. The difference for the NO_3 interchange was practically the same as for the SO_4 interchange. All fertilizers increased the rate of nitrification during the last 3 weeks, as compared to the unfertilized check. In the same period, K_2CO_3 caused a higher rate of nitrification than either KCl or SO_4 . K_2CO_3 was associated with the largest quantity of NO_3 present for any combination, both at the end of 3 weeks and at the close of the expt. Mono-calcium phosphate, during the last 3 weeks, tended to decrease the rate of nitrification for combinations contg. $NaNO_3$, but increased the rate of combinations with $(NH_4)_2SO_4$. E. F. S.

Comparative nutritive values of different salts of ammonia. ELEUTERIO PALISOC. *Philippine Agr.* 17, 37-43(1928).—In culture solns. contg. all of the principal nutrient radicals in various proportions, rice seedlings made relative growths of 128, 105 and 100 when the NH_3 was derived from NH_4NO_3 , $NH_4H_2PO_4$ and $(NH_4)_2SO_4$, resp. Throughout the series contg. $NH_4H_2PO_4$ the plants were well developed and of a normal color, but the leaf tips were dried out. The best culture soln. for rice is claimed to contain 1 part KH_2PO_4 , 4 parts NH_4NO_3 , 2 parts $Ca(NO_3)_2$ and 4 parts $MgSO_4$ with a total concn. of 0.00275 mol. per l. A. L. MEHRING

Agricultural sprays. VITTORIO CASABURI. *Atti congresso naz. chim. pura applicata* 2, 1045-52(1926).—The prepn. and uses of $NaOH$, $NaOH \cdot (NH_4)_2SO_4$, colloidal Cu, colloidal S and colloidal As and Pb sprays in agriculture are discussed. L. T. F.

Copper in combating blight. H. HOLLUNG. *Kühn-Archiv* 9, 79-96; *Chem. Zentr.* 1927, I, 1730.—In the choice of Cu salts to combat blight, care must be taken

that the germinating power of the crops is not injured. For this reason the sulfate, K cyanide and salicylate should not be used, whereas treatment for 0.5 hr. with 0.1% solns. of chloride, K chloride, nitrate, NH_4 sulfate, acetate, lactate or thiophenylate does no harm to the crops. With reference to the behavior toward blight spores, it was proved that some Cu salts do not, at the concn. above, kill the spores, but only change them to a dormant state, which in a suitable medium can be terminated. In all expts. 0.1% ammoniacal CuSO_4 soln. gave the best results. C. C. DAVIS

Petroleum oil as a carrier for insecticides and as a plant stimulant. F. R. DE ONG. *Ind. Eng. Chem.* 20, 826-7 (1928); cf. C. A. 21, 4009.—Petroleum oil as a carrier for insecticides has many attributes lacking in H_2O . The refining process usually applied to oils for foliage spraying removes much of the original insecticidal value necessitating the incorporation of more active chemicals. Expts. with the Brown apricot scale (*Leucanium corni*) using 2% emulsions of oils alone and with nicotine showed an av. mortality of 79.5% for kerosene alone and 92.4% for kerosene contg. 0.01% of free nicotine. The use of oil on foliage, either alone or in combination, must always be studied with reference to compatibility with the plant. E. F. SNYDER

Miscible carbon disulfide. WALTER E. FLEMING AND REINHOLD WAGNER. *Ind. Eng. Chem.* 20, 849-51 (1928).—A miscible CS_2 recently perfected is equally effective as emulsions of this compd. for destroying the soil-infesting stages of the Japanese beetle (*Popillia japonica*). Miscible CS_2 is a mixt. of CS_2 with castor oil, KOH, denatured alc. and H_2O . As high-grade chemicals are needed in the prepn. the qualities are specified. The method of prepn. of miscible CS_2 and the method of analysis of the finished product are described. E. F. SNYDER

Fumigation with calcium cyanide dust. H. J. QUAYLE. *Hilgardia* 3, 207-32 (1928); cf. C. A. 21, 3251.—The recent production of $\text{Ca}(\text{CN})_2$, a less stable compd. than the NaCN or KCN heretofore used for fumigation purposes, has made it possible to employ a different method of fumigation which consists of simply blowing the material or putting it down in thin layers in finely divided form into an enclosure. The atm. moisture acting on the small dust particles produces a sufficiently rapid generation of gas to make the method applicable even to citrus fumigation, where the fumigation period does not exceed 1 hr. Calcium cyanide, "A" in powd. form, first used in 1922, is largely used for citrus fumigation and for rabbits in Australia, for greenhouse and other fumigation generally, as well as for dusting in the open (without covers) for several insect pests. Because of injury the use of the "A" compd. was discontinued and grade "C" was substituted with much better results. Comparisons of dosage between grade "C," $\text{Ca}(\text{CN})_2$, and liquid HCN are given; the detns. are based on the effects on insects and on the actual gas concn. under the tent at different intervals. Less HCN is required in the $\text{Ca}(\text{CN})_2$ dust than in liquid HCN to effect the same mean concn. of gas under a canvas cover. In the case of a gas-tight fumigatorium the same amt. of HCN must be carried in the dust as in the liquid to give the same mean concn. within. There is less escape from gas through canvas covers where the source of the gas is the dust than where the source of gas is the liquid HCN. About 25% less gas is required in the dust than in the liquid. The data indicate that $1\frac{1}{4}$ oz. of "C" grade $\text{Ca}(\text{CN})_2$ dust is equiv. to 20 cc. of liquid HCN and there is approx. 25% less HCN in this amt. of the dust than there is in 20 cc. of HCN. The evolution of gas from "C" grade $\text{Ca}(\text{CN})_2$ was not greatly retarded when the relative humidity was as low as 20 to 22%, but this humidity did markedly retard the evolution of gas from "A" grade $\text{Ca}(\text{CN})_2$. The evolution of gas from both cyanides seemed to be independent of temp. within ordinary fumigation limits, that is, between 5° and 27°. C. R. FELLERS

Sodium and potassium bisulfates. Their use in agriculture (WAGUET) 18. Fat in the residual material remaining after the unwinding of the silk cocoon (JELAKOV) 27. Nature of clay and its significance in the weathering cycle (ROBINSON) 8.

Phosphatic fertilizers. MONTAN- UND INDUSTRIALWERKE, formerly Joh. Dav. Starck. Fr. 632,310, April 6, 1927. To obtain normal phosphates, substances forming stable compds. with F are added to the crude phosphate before or during the addition of acid. Such compds. are oxides or hydroxides of Si, Fe, Al, Ti, oxides of Mn, Cr, Mo or easily decomposable salts of these oxides.

Superphosphate. ANTONIO GAILLARD. Fr. 632,867, April 15, 1927. An app. is described for drying superphosphate in such a way as to increase its richness. Fr. 632,868 describes a similar app. in which the percentage of moisture is a little higher. Cf. C. A. 22, 2804.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Chemistry as applied to the brewing industry. OTTO P. RINDLEHARDT. Carling's Brewery, London, Ont. *Can. Chem. Met.* 12, 217-9(1928). E. H.

The effect of hydrogen ions in the brewing process. IV. Hydrogen-ion concentration and fermentation. G. HAGUES. *J. Inst. Brewing* 34, 362-76(1928); cf. C. A. 22, 1648.—Analyses and electrometric titrations were made on a series of lab. and brewery worts of varying original p_H values. From the figures obtained electrometric titration curves are given. This is the only correct way of demonstrating the buffering of beer or wort. During the first 12 hrs. of fermentation the total acidity remained const. while the p_H fell rapidly; the initial fall in p_H is attributed to the utilization by the yeast of assimilable substances and particularly the phosphates. After 12 hrs. the total acidity increased with little change in p_H . Most of the decrease in p_H value took place within 40 hrs. under the condition of the lab. expts. Mashies made with varying amounts of gypsum indicated that the buffering in the worts is not altered very much by the presence of gypsum, although total acidity is affected with a max. upon the addition of 20 grains per gallon to the mash water. Measurements of yeast reproduction in worts of varying p_H value gave two maxima, one at p_H 4.0 and the other at p_H 8.0 to 8.5; the first is the optimum p_H for pepsin, whereas the latter value is optimum for creptase.

PETER J. F. WEBER

Fermentation carbon dioxide. F. STOCKHAUSEN AND F. WINDISCH. *Wochschr. Brau.* 45, 277-81, 289-98, 305-11, 317-24, 329-33(1928).—The effect of CO_2 on ale fermentation was studied under different concns. of CO_2 from 70-mm. water pressure up to 1 atm. at temps from 2° to 20°. Bottom fermentation Race U was used. The rate of fermentation and growth was less with the yeast under pressure but the latter showed a much greater fermentation strength in a sugar soln. These high concns. of CO_2 produced a large healthy cell. The solid content of the pressure yeast was higher but the fat was about half that of the normal grown yeast. Since almost identical results were obtained with these greatly varying amts. of CO_2 the authors conclude that the action of CO_2 is not a chem. but an anaerobic one effecting the life processes of the cell. A. SCHULTZ

The fermentation of toddy and an account of the microorganisms producing it. M. DAMODARAN. *J. Indian Inst. Sci.* 11A, 63-74(1928).—Bacteria and yeasts found in toddy were isolated and described. Date and coconut toddy, regardless of locality contain the same types of microorganisms. Alcohol and acetic acid are formed. In addn. glycerol, lactic acid, succinic and tartaric acids are found present. Acetaldehyde was also found. Acetic acid is the chief volatile acid; butyric and propionic acids were not found. Bacteria, not yeast, are responsible for the unpleasant odors, scum formation and turbidity, and may possibly be eliminated by the difference in thermal death point of yeasts and bacteria. Exposing the wort for long periods for the production of vinegar is an inefficient method. C. N. FREY

Methanol in various alcoholic drinks. W. SEIFERT. *Oesterr. Chem.-Ztg.* 31, 65-8 74-7(1928).—Various European and American wines were examd. for their MeOH content. White wines from European grapes contain, as a rule, 7 cm. MeOH per 1000 cc. alc. and white wines from America of the "Noah" type contained higher percentages. The amt. of MeOH which is toxic varies with the individual. It may be well to make the detn. of the amount present a procedure, used also as an aid in detecting adulterations of European wines. C. N. FREY

The extraction of alcohol and of tartaric acid salts from wine residues. G. MEZZADROLI AND I. MUTTI. *Atti congresso naz. chim. pura applicata* 2, 1053-62(1926).—A discussion of various processes of sepn. of the important constituents of wine residues. With a national production of 45,000,000 hectoliters of wine providing 6,000,000 quin-

tals of residue there is a possible production of 200,000 hectoliters of alcohol and 150,000 quintals of cream of tartar. L. T. F.

Manufacture of alcohol from carobs and utilization of the by-products. GUIDO RIMINI. *Atti congresso naz. chim. pura applicata* 2, 995-1014 (1926).—A quintal of carobs yields 23 l. of alc., 10 kg. of CO₂ and 3 kg. of gum. The actual cost of material including transport is about 62 lire, while the value of the three products is 150 lire. L. T. F.

The spectrochemical detection of fruit wine in grape wine. O. F. KALBERER. Swiss Expt. Sta., Wädenswil. *Z. Untersuch. Lebensm.* 55, 214-30 (1928); cf. C. A. 21, 3419.—The addn. of SO₂ to wine has no great influence on the absorption spectra. Opalescence increases the absorption. In dark brown wines the color interferes with the delicacy of the test. WILLIAM J. HUSA

The composition of Marsala wines. P. SEGRE. *Atti congresso naz. chim. pura applicata* 2, 1038-44 (1926).—Summary of analyses of 37 wines. L. T. F.

Vinegar making about the year 1800. CURT LUCKOW. *Deut. Essigind.* 32, 227-30 (1928).—Historical. W. O. E.

The determination of antiseptic power, with special reference to hops. T. K. WALKER. *J. Inst. Brewing* 34, 61-4 (1928); cf. C. A. 22, 1432. Adrian Brown in 1913 isolated a bacterium from a sour beer which when added to varying concns. of hop decoction gave a measure of the antiseptic properties of the hops. Previously the hard resin and soft resin content were the measure of the hops value. Brown's method of biologically testing hops was improved by A. C. Chapman in 1925. By the biol. methods the effects of the α - and β -resins and the hops were detd. and found to be in the ratio of 3 to 1, and chemically the α -resin plus $\frac{1}{3}$ β -resin is a measure of the antiseptic value of the hops. Grading of a large series of hop samples by the biol. methods and by chemically detg. the α - and β -resin content gave results in close agreement with each other. PETER J. F. WEBER

Sulfites. HAROLD HERON. *J. Inst. Brewing* 34, 377-87 (1928).—"The limitation of the amount of SO₂ and the prohibition of the use of any other preservative in beer by the Public Health Preservatives in Food Regulations, made by the Ministry of Health, has given rise to questions bearing on the amount of sulfite which can be safely used without fear of exceeding the maximum." Two methods for detg. SO₂ are in use, each requiring distn. of the beer in a current of CO₂ after the addn. of acid. The first method condenses and collects the distillate in Br water. In the second method the SO₂ is introduced in the gaseous state into H₂O₂ and the resulting H₂SO₄ detd. by titration with standard alkali (cf. C. A. 21, 2510, 2742). H. used the first method. Malt contributes 3 to 8 p. p. m. SO₂ to the wort, sugars used as adjuncts, practically none. Malt ext. had 25-50 p. p. m. Hops varied considerably, contributing from 1 to 10 p. p. m. to the wort. Because sulfites combine with certain of the wort constituents to form stable compds. a considerable amt. of the SO₂ survives the kettle boiling process even when sulfites are added to the mash. Tests on adding sulfites to beer at the rate of 57 p. p. m. SO₂ and using K₂S₂O₈, a Na and K sulfite, a Na, K and Mg sulfite, together with a CaSO₃, showed that in order to secure the max. preservative effect all the available SO₂ should become sol. immediately. After 28 days the loss of SO₂ was approx. 25% in the test beers. PETER J. F. WEBER

Dextrin not saccharified by wine yeast in distillery potato mash. ADOLF JOSZT AND JOZEF TROJAN. *Przemysł Chemiczny* 11, 317-31; *Chem. Zentr.* 1927, II, 649.—From a distillery potato mash fermented with wine yeast was obtained with a diastase, a not completely fermentable mixt of dextrins, which by means of EtOH was sepd. into 4 fractions. These fractions were readily distinguishable by their reducing power, by their optical rotation, by their tendency to decomp. and by their fermentation with diastase, which varied from 25 to 75%. The action of diastase increased with the soly. of the fractions in EtOH. By the simultaneous action of diastase and distillery or wine yeast, the dextrins were fermented to a great extent, the fraction most sol. in EtOH almost completely. C. C. DAVIS

Autolysis of bottom beer yeast. W. WINDISCH, P. KOLBACH AND R. FR. ROTHENBACH. *Wochschr. Brau.* 45, 251-6, 261-5, 281-5, 298-302 (1928).—In fresh yeast kept at low temps. a gradual autolysis accompanied by self-fermentation takes place. This natural course is greatly changed by drying or the addn. of antiseptics to the yeast. The optimum p_H for the proteolytic enzymes in a fresh untreated bottom beer yeast is 5; for a CHCl₃-plasmolyzed yeast 5.7 to 6.2. The opt. temp. at p_H 5 for a 3-hr. autolysis is 55° and for one of 6-hrs. 52°. During these intervals 79 and 89%, resp., of the total albumin N present is hydrolyzed. A larger yield of hydrolysis products

is obtained in the same period of time by changing the p_H from 5 to 6.25 when most of the albumin has been converted to peptones than by keeping a const. p_H of 5.

A. SCHULTZ

The struggle between yeast and wild organisms in fresh malt. OTTO HUMMER. *Centr. Bakt. Parasitenk. II Abt.* 71, 407-16(1927).—A study of the changes in fermentation induced by various wild yeasts and bacteria. Closure with a H_2SO_4 valve is better than cotton.

JOHN T. MYERS

The possibility of using fruit sugar for the manufacture of compressed yeast with particular reference to the utilization of carob sugar. G. MEZZADROLI AND S. SCHIAVI. *Alli congresso naz. chim. pura applicata* 2, 1015-8(1926).—A quintal of carobs under optimum conditions for alc. production yields about 20 l. of alc.; when used for yeast manuf. it yields about 12 l. of alcohol and 12-14 kg. of yeast. Yeast obtained from the fermentation of molasses or of grain differs from and is inferior to that obtained from the fermentation of fruit sugar. The author stresses the economic advantages of the utilization of carob sugar for this purpose.

L. T. F.

The growing of yeast with organic and inorganic nitrogen. H. CLAASSEN. *Chem.-Ztg.* 52, 497(1928).—C. states that Wohl (C. A. 22, 2807) confused org. sol. N with effective N. Only 40% of total N of beet molasses is assimilable by yeast according to W. but 50% is assimilable according to results given by the Garungs Institute. In the presence of more than optimum amt. of NH_3 the yeast fails to utilize org. N to any great extent. The curve I representing yield falls sharply when high amts. of N are given and more than 10% N is ammonia N. The curve representing N content of yeast continues to rise with increasing amts. of inorg. N. The curves II and III by Wohl representing optimum N concns. do not hold for higher concns., therefore W. has committed an error.

C. N. FREY

The growing of yeast with media containing organic nitrogen and ammonium salts by the aeration method. II. A. WOHL. *Chem.-Ztg.* 52, 498(1928); cf. preceding abstract. The old procedure did not involve utilization of organic N from malt. The old ideas do not apply but the subject which is pertinent pertained to the utilization of inorganic N in presence of org. N or when it is partly replaced with org. N. The coeff. 0.4 for org. N of molasses was formulated by Wendl. W. states that he does attempt to maintain that the curves representing max. growth with minimum concn. of N would hold for higher concns. The relative amt. of org. to inorg. N in the patent specification need not be strictly adhered to according to a recent court decision. Reply. H. CLAASSEN. *Chem.-Ztg.* 52, 498-9(1928).—W. admits that the investigations and curves on which his articles and patents were based were in error regarding sol. N as distinguished from assimilable N. W. has cited various investigations stating that org. N is replaceable by inorg. N and the latter is said to be of equiv. nutritive value. This relation was shown by C. not to hold for higher N concns.

C. N. F.

The role of phosphorus in the life of yeast in alcoholic fermentation. E. ELION. *Hochschr. Brauw.* 45, 178-82, 192-5(1928).—See C. A. 22, 1174.

A. SCHULTZ

Yeast. ARTHUR P. HARRISON (to The Fleischmann Co.). U. S. 1,676,437, July 10. Yeast is propagated, with aeration, in a yeast nutrient soln. until the soln. has attained a substantially const. Balling; a portion of the yeast-contg. liquid is then withdrawn, and yeast-nutrient materials are added to restore approx. the initial conditions of vol. and density, and the yeast-propagation is repeated, with aeration. Cf. C. A. 21, 3420; 22, 3017.

Cellulose fermentation. HERBERT LANGWELL and ELOI RICARD. Can. 282,038, July 31, 1928. Fatty acids are produced by fermenting a mash of cellulosic material by the action of thermophilic bacteria with high yields, controlling the acidity of the mash so that the H-ion concn. is maintained within the limits 10^{-9} and 10^{-5} measured in the bulk of the mash, and supplying the nutrient for the bacteria in part by waste liquor.

Cellulose fermentation. HERBERT LANGWELL and WILLIAM A. BURTON. Can. 282,039, July 31, 1928. A mash formed in part of distillery wastes is subjected to fermentation by thermophilic bacteria, the acidity of the mash being controlled so that the H-ion concn. is within the limits 10^{-9} and 10^{-5} measured in the bulk of the mash, by a method selected from the following, a compound of an alk. metal of which the phosphate is substantially sol. in H_2O or a compd. of an alk. earth metal of which the phosphate is substantially insol. in H_2O , in which case there is added to the mash a substance to cause the formation of an insol. alk. earth compd.

Fermentation vats. MAURICE G. APPERT. Fr. 632,131, April 4, 1927. A fermentation or defecation vat is provided with a coil for coil water, etc., and a manhole

cistern at the side to collect the coagulant by overflow or skimming, and maintain the wort at a const. height.

Alcohol. KISAKU MORIKANA (to Samuel C. Prescott). Can. 282,383, Aug. 7, 1928. A sterilized sugar-bearing mash including a protein nutrient of the fermenting bacillus is prepd. and has added thereto a culture of bacteria, derivable from fermented rice or koji, sufficiently resistant to heat to withstand 80° for about 5 min. and capable of producing butyl alc. and isopropyl alc. by fermentation, in the pressure of air, of a sterilized koji mash, and maintaining the same at a suitable fermenting temp.

Solid alcohol composition. H. OHLE and J. OTHMAR-NEUSCHLEER. Brit. 281,662, Nov. 30, 1926. A solidified gel is obtained by adding to EtOH a small proportion (suitably about 1-2%) of an alkali or alk. earth metal salt of the sulfuric acid half esters of acetone derivs of sugars and multivalent alcs. such as diacetoneglucose, diacetonegalactose, α - and β -diacetonefructose and acetoneglycerol. The K salt of α -diacetonefructosesulfuric acid is especially suitable for the purpose. The gel formed is non-toxic and suitable for making beverages, foods, medicinal and "technical" preps.

Glycerol. SOCIÉTÉ DES ÉTABLISSEMENTS BARBET. Fr. 632,260, July 19, 1926. See Brit. 274,519 (C. A. 22, 2235).

Glycerol by fermentation. JAMES W. LAWRIE (to E. I. duPont de Nemours & Co.). U. S. 1,678,150, July 24. In producing alc. and glycerol, a molasses mash is fermented with yeast and during the fermentation there is added a mixt. of substantially the same compn. as the incinerated ash of a fermented molasses ash, which serves to increase the yield of glycerol.

Yeast. HERMANN BUCHER. Fr. 632,848, Mar. 21, 1927. Examples are given of nutrient materials which are sol. in water and do not give rise to excessive acidity during the growth of the yeast, such as urca ammonium phosphate and ammonium nitrate. The same nutritive soln. is used several times after removal of the yeast formed and after sterilization. An app. is described.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Some non-alkaloid components of the *ipecacuanha*. O. KELLER. *Festschrift A. Tschirch* 1926, 85-98; *Chem. Zentr.* 1927, I, 2916, cf. C. A. 11, 3093. An alkaloid-free, alc. ext. of the roots of *Uragoga ipecacuanha* was analyzed. The substance called in the literature "ipecacuanhic acid" was found to be a *glucotannoid* or a mixt. of several *glucoside tannins* of weakly acid character, of which glucose and phlobaphene were cleavage or transformation products. The chief quantity was not in the Pb acetate ppt. but was in the filtrate. Neutral Pb acetate did not ppt. the compd. A brown color was formed in all cases with ferric salts. An acid *saponin*, malic acid, citric acid, and small quantities of fat and resins were also found. C. C. DAVIS

The tubers of the *Pinellia tuberifera*. C. MANNICH and SZE. YIH. Univ. Frankfurt. *Festschrift A. Tschirch* 1926, 158-61; *Chem. Zentr.* 1927, I, 2754. The origin, production, nature and use of the tubers of the Chinese and Japanese *Pinellia tuberifera* (Araceae) are described. Data found in an old Chinese book have been extended by Brandt. The morphology and anatomy of rhizome tubers are similar to those of *Arum maculatum*. Pulverized tubers showed the following % compn.: water 12.3, ash 2.1, Et₂O-ext. 3.0, crude fiber 2.3, N 0.74, N substances 4.6, starch 69.3. A small quantity of a hemolysin was found. The drug produced a strong irritation of the pharynx and esophagus. Pharmacol. expts. by Lautenschlager on animals showed that there is no poison in the tubers. C. C. DAVIS

A method for the determination of ethereal oils in drugs. J. STAMM. Univ. Dorpat. *Festschrift A. Tschirch* 1926, 283-7; *Chem. Zentr.* 1927, I, 2759-60. The method described has been used by S. for several yrs. The ethereal oil is isolated from small quantities of drug by distg. with water and collecting the distillate in a measuring vessel which has previously been filled to a definite mark with CCl₄. The vessel is shaken until the oil is dissolved, the mixt. is then centrifuged and the quantity of oil detd. by the increase in vol. The app. and the procedure are described, with diagrams of the app. CCl₄ was chosen on account of its low soly. in water (0.08:100) and its high d. The measuring vessel, termed an "*oleometer*," is made by "Verkaufsvereinigung Göttinger Werkstätten." In all expts. a loss of 0.01 cc. (1 graduation mark) must be added as a correction factor. C. C. DAVIS

Greek licorice and its juice. EM. EMMANUEL. Univ. Athens. *Festschrift A.*

Tschirch 1926, 288-90; *Chem. Zentr.* 1927, I, 2753.—A survey of the occurrence, gathering, prepn. and use of Greek glycyrrhiza. The following data give the % compn. of *Glycyrrhiza glabra* L. from Peloponnesus and from Asia Minor, resp.: dry glycyrrhiza: glycyrrhizin 7.316, 5.895; d-glucose 1.516, 1.398; sucrose 2.385, 2.678; dry ext. 31.167, 30.018; ash 4.085, 5.816; water 8.117, 8.891; juice: glycyrrhizin 18.812, 12.990; glucose 3.956, 4.875; sucrose 4.878, 5.618; starch + gums 20.761, 22.702; water 10.695, 13.412; ash 8.011, 7.510; water-insol. 5.207, 8.900. C. C. DAVIS

The saponin of Primula root. II. L. KOFLER AND M. BRAUNER. *Festschrift A. Tschirch* 1926, 351-6; *Chem. Zentr.* 1927, I, 3009; cf. K., C. A. 18, 3449.—When the method used for obtaining saponin from *Primula veris* was applied to the obtaining of saponin from *Primula elatior*, the elatior saponin was a gelatinous ppt. which could not be crystd. This saponin is sol. in NaOH, KOH, alk. carbonates, EtOH and MeOH. The hemolytic index is about 50% higher than that of primulic acid. At 218° elatior saponin becomes yellow-brown, and it m. 224-5°. Its toxicity is 0.5 as great as that of primulic acid. Heated in water with NaOH or Na₂CO₃, elatior saponin ppts. a white cryst. compd., which is also formed directly from *Primula elatior* by boiling its alc. ext. with aq. NaOH or Na₂CO₃. When boiled with aq. NaOH, primulic acid gives no ppt. The elatior-Na compd. is insol. in 96% EtOH and the veris-Na compd. is difficultly sol. The elatior Na compd. can be salted out of its aq. soln. by NaCl, whereas the veris-Na compd. cannot be. By electrodialysis, primulic acid is obtained from the veris-Na compd. and unchanged elatior-saponin from the elatior-Na compd. The veris-Na compd. cannot be obtained from crystd. primulic acid, but only directly from the drug. C. C. DAVIS

The chemistry of iodocatgut. STORP AND ABEL. *Veröffentl. Gebiete Heeres-Sanitätswesens* 1926, No. 80, 48 pp.; *Chem. Zentr.* 1927, I, 3110.—The methods of prepn. of iodocatgut through soaking of raw, degreased catgut in a KI soln. of I were investigated, and the quantity of I absorbed was detd. I is present as free I, HI and protein compds., and in insufficiently purified raw catgut as alkali iodide as well. On long standing, the free I disappears completely and the total I content decreases. The I and the acid have an unfavorable effect on the catgut and it is therefore recommended to remove excess I and acids with NaOAc-Na₂S₂O₃ soln. and to sterilize the material at 100.5°. For use it may be kept a short time in a flask with water and I to impregnate with free I. C. C. DAVIS

Loosely bound sulfur in pituitary extracts. M. X. SULLIVAN AND M. I. SMITH. *Hyg. Lab. U. S. Pub. Health Service Pub. Health Repts.* 43, 1334-42(1928).—A study of pituitary exts. to det. if the S content varies with the physiol. activity as is the case with glutathione and insulin. The physiol. activity was detd. by the ability to raise the blood pressure of anesthetized dogs. In 21 exts. of posterior lobe and 12 of the anterior portion it was found that the physiol. activity was roughly proportional to the loosely bound S. Inactive exts. did not give the test for this form of S. However, a destruction of the physiol. activity of a posterior lobe ext. by boiling for 30 min. with 0.5% HCl did not abolish the loosely bound S. H. J. DEUEL JR.

Preparation of liver extract. N. KETLEMANS AND P. VAN DER WIELEN. *Pharm. Weekblad* 65, 709-11(1928).—The use of glycerol simplifies the process of purification, serves as a preservative and disguises the unpleasant liver taste. Grind up 1 kg. of fresh beef or pork liver and mix with 1100 g. 90% EtOH and 5.3 cc. 4 N H₂SO₄. Let stand 24 hrs. in a cool place, strain and press. Mix the press cake with 200 g. 60% EtOH, strain and press as before. Filter the combined exts., evap. the EtOH *in vacuo* until the liquid begins to foam, filter and evap. further. To the residue add 25 g. glycerol of sp. gr. 1.25 and evap. below 80° to a thin sirup, then add glycerol to make 100 g. Ten g. of this ext. corresponds to 100 g. liver. Preserve in a well-stoppered bottle. The following recipe is given for a "Mistura extracti hepatis"—glycerol ext. as above 20 parts, glycerol 10, cinnamon water 30, water, q. s., 90. A. W. DOX

Pharmacy in British East Africa. GEORGE CECIL. *Apoth. Ztg.* 43, 781-2(1928).—Description of conditions prevailing in this British colony. W. O. E.

Testing emetine hydrochloride. S. KROEL. *Apoth. Ztg.* 43, 791(1928).—The evaluation of this compd. as prescribed by the D. A.-B. VI. is discussed. W. O. E.

Chinese drug store. ALBAN VOIGT. *Pharm. Ztg.* 73, 833-4(1928).—A description of a typical Chinese apothecary and its activities. W. O. E.

Chemical characterization of drugs. L. ROSENTHALER. *Pharm. Ztg.* 73, 837-9(1928); cf. C. A. 22, 1212.—Peru balsam, tolu balsam and styrax are discussed. A study has been made of some 21 samples of Peru balsam (genuine, artificial or imitation, or otherwise questionable) with respect to I no., cinnamein content, behavior toward petr. ether, Et₂O and NH₃. The cinnamein content varied from 53.4 to 74, the I no.

from 1.6 to 64.1. The I no. of tolu balsam ranged from 95 to 121, that of styrax from 70 to 91. W. O. E.

Alcohol determination in essential oils. I. G. OBERHARD AND N. A. KUBASSOW. *Pharm. Ztg.* 73, 839-41(1928).—In estg. the alc. of essential oils, recourse is had to a detn. of the ester no. and the acetyl no., these values being thereupon applied to the formulas: $e = (M/20) (b/n)$ and $m = (M/20) (a/s - 0.021a)$, in which e = content of esterified alc., M = mol. wt. of that alc., n = wt. of sample taken, and b = no. of cc. 0.5 N alc. KOH soln. necessary to saponify the esters in n g. of the oil; m = content of free alcohol, s = wt. of acetylated oil, a = no. of cc. 0.5 N alc. KOH soln. necessary to saponify the esters in s g. of acetylated oil, e and m are in percentages. By working on controls made up of paraffin oil as vehicle and menthol, borneol and thymol, resp., the free and combined alcs. were detd. in 3 series of expts., and the results tabulated. The time required properly to acetylate menthol-contg. oils was found to be 75 min., for thymol and 105 min. for borneol. The results calcd. from the formulas came regularly somewhat high, notably in the absence of determinable amts. of ester. W. O. E.

Titrimetric estimation of santonin in pharmaceutical preparations. A. LANGER. *Apoth. Ztg.* 43, 815(1928).—Since santonin tablets and confections frequently contain phenolphthalein, the santonin is 1st extd. with C_6H_6 in the heat, or if fats (cocoa butter, etc.) are present, they are successfully removed by treating the crude santonin with petr. ether satd. with santonin (0.05 g. per 100 cc.). Working with com. santonin, dissolve 0.2 to 0.3 g. in 20 cc. EtOH contained in an Erlenmeyer flask, add 5 drops phenolphthalein soln. and about 20 cc. of 0.05 N alc. KOH soln., digest by immersion in a boiling water bath $\frac{3}{4}$ of an hr. after suitable connection with a reflux, then titrate with 0.05 N HCl. Toward the end of the titration a pure bright yellow color finally develops in the santonin soln. The transition is sharply defined. For the EtOH itself some 0.35 to 0.4 cc. 0.05 N KOH are required, for which a suitable correction is made. The values obtained with pure santonin afford the necessary data to develop the santonin factor for unknowns. In the case of confections, an amt. of the sample is taken involving 0.2 to 0.3 g. santonin. Rub up the kernels with washed sand, dry at 80° to remove any volatile esters, then shake the cooled powder with petr. ether (satd. with santonin), decant and ext. with 2 like portions of petr. ether before filtration. Press the filtered residue between filter paper, then ext. with C_6H_6 (50 g. for 7 g. of kernels). After repeated shaking, allow to stand 14 hrs., pass through a pledget of cotton, evap. a weighed aliquot (contg. about 0.15 to 0.16 g. santonin) of the filtrate to dryness at 80° and weigh the residue (crude santonin). Wash with petr. ether satd. with santonin, then titrate as above. W. O. E.

Detection of isopropyl alcohol in spirits and tinctures. G. REIF. *Arch. Pharm.* 266, 382-94(1928).—Isopropyl alc. is detected in spirits and tinctures of the Ger. Pharm. by a procedure involving the production of a red color through the presence of piperonal. Substances contained in such products and calcd. to interfere can be removed by prior treatment with animal charcoal. This applies also to denaturants. The piperonal procedure applies as well to the detection of isobutyl alc. in spirits and tinctures. W. O. E.

Estimation of arsenic in drugs. E. SCHULEK AND P. V. VILLECZ. *Arch. Pharm.* 266, 411-5(1928).—Two rapid methods are described: *I. Macroprocedure.*—Introduce the finely powdered substance (equiv. to 5-100 mg. As) or 1-2 cc. of the evapd. liquid into a 100-cc. flask, add 3-5 cc. 30% H_2O_2 , rotate, then pour 10 cc. concd. H_2SO_4 down the sides and again rotate. Should the resulting liquid not be clear add more H_2O_2 . Heat to boiling and on appearance of any brownish cast remove with H_2O_2 . Continue boiling until SO_3 fumes develop, cool and add 10-20 cc. Cl-free $(NH_4)_2SO_4$ through a long funnel tube, being careful that none of this reagent touches the side of the flask. Boil 10 min. longer to expel SO_2 , cool and carefully add 20 cc. of H_2O , 10 cc. KBr, then titrate with 0.1 N $KBrO_3$ to a permanent yellow. *II. Microprocedure.*—Weigh into a flask (Jena or Pyrex) the sample equiv. to 0.1-5 mg. As, mineralizing with 1-2 cc. H_2O_2 and 3 cc. concd. H_2SO_4 . Reduce with 8-5 cc. $(NH_4)_2SO_4$, boil 10 min., cool the liquid with 10 cc. H_2O , or 20% H_2PO_4 , transfer quant. to a 40-cc. test tube (with ground glass stopper), add 3-5 cc. KBr, 1 cc. CCl_4 and 2 drops satd. aq. KI, then titrate with 0.01 N $KBrO_3$ with vigorous shaking till the liquid becomes colorless. A control titration should be made with 2 cc. pure concd. H_2SO_4 , 10 cc. H_2O (or 20% H_2PO_4), 3-5 cc. KBr and 2 drops satd. aq. KI. W. O. E.

Dextrin as a cosmetic raw material. SAMUEL ABRAMSON. *Am. Perfumer* 23, 295-6(1928).—A discussion of a product (corn, potato and tapioca dextrin) whose use in cosmetics is steadily growing. W. O. E.

Pharmacognostic investigations during the year 1927. RICH. WASICKY. *Arch. Pharm.* 266, 416-30(1928).—A résumé of work accomplished during this period.

W. O. E.

Drug activities during the year 1927. J. HERZOG. *Arch. Pharm.* 266, 430-45 (1928); cf. C. A. 22, 2809.—An address.

W. O. E.

Color reaction of mannitol. LAD. EKKERT. *Pharm. Zentralhalle* 69, 433(1928).—On oxidizing 0.2 g. mannitol in 15-20 cc. H_2O with 3% $Br-H_2O$ 15 to 20 min. in the heat, and expelling the Br excess by boiling till the liquid is reduced to 5 cc., a drop of this product admixed with 0.01 g. of the following substances with subsequent addn. of 1 cc. concd. H_2SO_4 gives in the cold and on warming, in the case of phenacetin: rose-red, wine to ruby-red; resorcinol: golden-yellow, saffron to deep blood-red; α -naphthol: brownish onion-red, brown; codeine: violet-rose to rose-violet; morphine: yellowish red, rose, peach-blossom, wine, ruby to garnet-red.

W. O. E.

Terpene-free essential oils. PIETRO LEONE. *Atti congresso naz. chim. pura applicata* 2, 839-69(1926).—L. recommends distn. at reduced pressure until 80% of the material has distd. over, or until that fraction is reached which is inactive to polarized light. From this point on the optimum yield of de-terpenated oil is obtained. Fractionation of this material yields partly terpenated and completely deterpenated oils. The fractionation of natural oil of lemon is illustrated in detail. L. T. FAIRHALL

De-terpenated essences of the acid fruits. GIOVANNI ROMEO. *Atti congresso naz. chim. pura applicata* 2, 870-99(1926).—R. describes in detail the manuf., physical and chem. properties and methods of analysis of de-terpenated essence of lemon, sweet and bitter oranges, mandarin and bergamot. The sophistication of these essences with artificial esters is discussed and expts. undertaken with a view of detecting such adulteration are described.

L. T. FAIRHALL

Denicotinized tobacco. E. M. BAILEY, O. L. NOLAN AND W. T. MATHIS. Conn. Agr. Expt. Sta., *Bull.* 295, 338-51(1928).—Tobacco is usually denicotinized by a re-sweating process accomplished by treatment with superheated steam by exposure in vacuum chambers. Solvents have been used but with indifferent success. Seventeen samples of denicotinized tobaccos were compared with ordinary tobaccos with reference to total nicotine, free nicotine and N distribution. The "denicotinized" products varied considerably in nicotine content as do ordinary tobaccos. As a group, they were found to contain somewhat less nicotine than tobacco not specially processed, the comparison being based upon abs. for each of the 2 classes. Some denicotinized products contained as much nicotine as is likely to be found in ordinary tobaccos; a few contained substantially less. The lowest nicotine content found in any sample was about 0.75%. The lowest value for ordinary tobacco, quoted from analyses made elsewhere, is about 1.50% but this is probably unusual; however, certain types of tobacco, Havana, Porto Rican and Turkish, for example, may contain normally as little as 1% of nicotine. None of the "denicotinized" tobaccos included in this investigation are sufficiently low in nicotine to warrant unrestricted indulgence on the part of consumers who suffer ill effects from this alkaloid. It may be found to be com. possible to make the removal of alkaloid from tobacco practically complete as has been done in the case of coffee for example; but whether the finished product will retain any of the qualities for which tobacco is prized for smoking purposes is an obvious question. No attempt has been made in this study to det. whether reduction in nicotine has been accomplished entirely, or in part, by the use of fillers. Free nicotine appears to be due to the dissociation of the nicotine salts of the org. acids in the tobacco leaf. The harsh and irritating effects experienced when smoking certain tobaccos are attributed to this form of nicotine. Denicotinized tobaccos do not differ in any conspicuous degree from ordinary tobaccos in this respect. N in the form of nitrates and of NH_3 are practically identical in both classes of tobaccos. The amt. of nitrate found does not indicate that tobaccos are nitrated to improve burning capacity.

C. R. FELLERS

Note on the test for purity of sodium benzoate and caffeine sodio-benzoate of the Austrian Pharmacopeia VIII. OTTO PROCKE. Charles Univ. Prague. *Casopis Československého Lékárnictva* 6, 1-2(1926).—The test for Cl in $BzONa$ of the Austrian Pharm. VIII is considered inadequate. P. proceeds as follows: To det. chlorides, dissolve 1 g. $BzONa$ in 10 cc. H_2O , add 1 cc. concd. HNO_3 and several cc. of ether and titrate with 0.02 N $AgNO_3$ and 0.02 N NH_4CNS . To det. total Cl , incinerate the sample in a Pt crucible before proceeding as above. Of 3 samples of $BzONa$ tested, 1 sample contained all the Cl as chloride, while in the other samples, $1/4$ and $1/10$, resp., of the total Cl was present as chloride.

WILLIAM J. HUSA

Oxidation of arsenite in solution arsenicalis Fowleri of the Austrian Pharmacopeia VIII, and determination of arsenic. OTTO PROCKE. *Casopis Československého Lékař-*

nictus 6, 53-6(1926).—P. combined the method of Mohr for detn. of As^{III} with Rosenthaler's method for detn. of As^{V} and applied the combined method to the study of the oxidation by atm. O_2 of the arsenite in "solutio arsenicalis Fowleri" of the Austrian Pharm. VIII. The samples were stored in diffused light at 15-20°. One sample out of 8 stored for 3.5 years showed 35% oxidation, the other 7 less than 2%. In 2 samples kept for 17 months, the % oxidation was 0.6 and 12.3, resp. The excessive oxidation in two cases is attributed to faulty prepn. or improper storage. The combined method of analysis is as follows: To 10.00 g. of Fowler's soln. in a glass-stoppered flask add 1 g. NaHCO_3 and det. As^{III} by titration with 0.1 N I. Then add 2 g. NaHCO_3 and 25 cc. of 38% HCl, and if the amt. of 0.1 N I consumed was less than 19 cc., add also 0.5 g. KI. After 8-10 min. titrate the mixt. with 0.1 N $\text{Na}_2\text{S}_2\text{O}_3$. The amt. of As^{V} originally present is calcd from the difference in the titrations. WILLIAM J. HUSA.

The detection of isopropyl alcohol in spirits by means of piperonal. G. REIF. Imperial Board of Health. *Z. Untersuch. Lebensm.* 55, 204-14(1928).—To detect iso-PrOH in spirits, liniments, tinctures, etc., dil. 1 cc. of the alc. distd. from 10 cc. of the sample with 2 cc. H_2O ; treat 0.3 cc. of the mixt. with 2 cc. H_2O and 0.04 g. medicinal charcoal (D. A. B. 6) and filter through a dry filter; add 5 cc. of a 0.5% soln. of piperonal in alc., then 20 cc. of concd. H_2SO_4 and shake the mixt.; heat 5 cc. of this mixt. on a H_2O bath for 4 or 5 min. If iso-PrOH is present a red to red-brown color appears.

WILLIAM J. HUSA.

Further observations on the accuracy of the cat method for the assay of digitalis. CHAS. C. HASKELL. Medical College of Va. *J. Pharmacol.* 33, 207-17(1928).—From a large number of expts. it is concluded that the cat method of assay of digitalis preps is only an approx. accurate measurement of toxicity. C. RIEGEL.

Pharmaceutical preparations containing lactic acid organisms. JACINTO PLACERES. *Anales oficina quim provincia (Lu Plata)* 1, 71-89(1927).—Sixty different products contg. lactic acid organisms for therapeutic use were examd. A 3% lactose milk medium was found to be most suitable for the growth of the germs. One cc. of a fluid or 0.5 g. of a solid prep. was placed in 100 cc. of the sterile medium. Incubation was carried out at 37° for 48 hrs. During the incubation period the flasks were agitated several times to break up the masses of casein. Several glass beads were usually placed in each flask to aid in the comminution of the curd. Ten cc. samples of culture were removed and titrated with NaOH, phenolphthalein being used as indicator. The liquid preps. produced the largest amts. of lactic acid, from 11.70 to 20.61 g. per l. The objectionable by-products such as formic, acetic and butyric acids, aldehydes and acetone were also estimated. Only the first two were found to be present. The quantity of formic acid produced varied from 0.014 to 0.081%, acetic acid from 0.123 to 0.945%. An attempt was also made to det. the amt. of proteolysis. M. H. SOULE.

A method for the quantitative estimation of sulfur combined as sulfides in potassa sulfurata (liver of sulfur). CHARLES H. ROGERS. *J. Am. Pharm. Assoc.* 17, 658-61(1928).—The U. S. P. X requires that a given wt. of liver of S shall ppt. all the Cu in a weighed amt. of Cu salt. If the product be substandard Cu will be found in the filtrate but no method is provided for detg. the degree of the fault. R. detcs. the Cu in the filtrate by pptg. as CuS and igniting to CuO . The amt. of Cu salt consumed is obtained by difference. Sample 1, 15.19 91%; sample 2, 14.11-44% S. L. E. W.

A source of error in the assay of belladonna plaster. JOSEPH L. MAYER. Brooklyn Coll. of Pharmacy. *J. Am. Pharm. Assoc.* 17, 661-3(1928).—In the general directions for the assay of alkaloids the U. S. P. X. directs that the extn. of the drug extd. with acid must be continued until the addn. to the acid soln. of $(\text{KI})_2\text{HgI}_2$ or I soln. fails to give a cloudiness. M. finds that in belladonna plaster the acid ext. contains considerable EtOH and does not give ppts. with either reagent. Precaution must be taken to evap. the EtOH before applying the test. L. E. WARREN.

Neutral glass for vials (GIORDANI) 19. Influence of various factors on the accumulation of alkaloids in the leaves of *Datura stramonium* L. var. *inermis* (FLOSKI) 11d. H-ion concentration and pH —an explanation (CALDWELL) 2. Active constituent of the true coto bark (SPATH, WESSLEY) 10. Application of x-ray crystal analysis to the problems of chemistry (SHEARER) 3. Apparatus for therapeutic application of chlorine by inhalation. CHARLES F. WALLACE and JOHN C. BAKER (to Wallace & Tiernan Products, Inc.). U. S. 1,678,625, July 24.

Alkaloids. WELLCOME FOUNDATION, LTD., T. A. HENRY and T. M. SHARP Brit. 281,582, Aug. 16, 1927. Three alkaloids ("A", "B" and "C") are obtained from the seeds of *Picralima klataneana*, Pierre. The ground seeds are freed from fat and extd. with EtOH; the ext. is dried and further extd. with dil HCl, clarified with charcoal and filtered. The alkaloids may be pptd. with Na_2CO_3 to render the filtrate alk. or may be first carefully dild. with H_2O , which ppts. a portion of "A" and a further ppt. then may be obtained by rendering the soln. alk. This ppt. may be sepd. into ether-sol. and ether-insol. portions and from the former alc. dissolves "B" and leaves "C," the ether-insol. portion is "A."

Sedatives and hypnotics. J. D. RIEDEL A-G. Brit. 281,365, Aug. 27, 1926. Isopropylallylactic acid is treated with thionyl chloride and the acetyl chloride thus formed is heated with urea to form isopropylallylacetyleurea or the latter may be obtained by treating the isopropylallylacetylechloride with NH_3 to form the acetamide and heating this with cyanic acid for some time. Di-Et *sec*-butylmalonate is transformed into its Na compd. and this is heated with allyl bromide and the product saponified; the *sec*-butylallylmalonic acid thus formed is converted into the corresponding acetic acid and the latter is treated with thionyl chloride and then with urea to obtain *sec*-butylallylacetyleureide.

Antirachitic principles of cod-liver oil. THEODORE F. ZUCKER (to University Patents, Inc.). U. S. 1,678,454, July 24. Cod-liver oil is treated with alc., the fatty acids in the alc. ext. are saponified, the Ca salts of the soaps thus formed are pptd. and the antirachitic principles are extd. from the pptd. soaps, *e. g.*, by extn. with acetone.

Organic gold compounds. ALPHONSE GAMS and PAUL SCHEIDEGGER (to Soc. anon. l'ind. chim. à Bâle.) U. S. 1,678,429, July 24. Stable complex Au compds. which may be used as therapeutic agents are formed by reaction of a Au compd. such as Au chloride upon a water-sol. nucleate such as that of Na.

Ammonium 3-acetylmino-4-hydroxybenzene arsonate. ERNEST FOURNEAU (to Les établissements Poulenc Frères). U. S. 1,677,964, July 24. See Brit. 264,797 (C. A. 22, 304).

Easily soluble local anesthetics of the *m*-aminobenzoic acid ester series. OTTO BILLETER, ERNST ROTILIN and JULIUS PEYER (to Chemische Fabrik vorm. Sandoz). U. S. 1,678,317, July 24. See Can. 274,214 (C. A. 21, 4028).

Cyclopentenyl-substituted aliphatic acids. ROGER ADAMS, CARL R. NOLLER and JAMES A. ARVIN (to Abbott Laboratories). U. S. 1,678,175, July 24. Cyclopentenylethyl bromide is made from cyclopentenylethanol by treating while cold with PBr₃ in toluene, then allowing the temp. to rise. It b_{16} 71-2° (uncor.). Its dry ether soln. is converted into cyclopentenylethylmagnesium bromide and this product further dild. with dry ether and condensed with methyl 8-aldehyde-octanoate and the resulting product decomposed with H_2O to obtain methyl 9-hydroxy-*dl*-hydnoicarpate, which is an oil b_4 177-9° (uncor.). Sapon. of this ester with alc. KOH yields 9-hydroxy-*dl*-hydnoicarpic acid, which, after recrystn. from acetone, m. 62.0-62.8° (cor.). By reaction of cyclopentenylethyl bromide on Et sodiomalonate, by refluxing in abs. alc., Et cyclopentenylethylmalonate is produced. It b_4 147-8°. By sapon. of this ester with aq. NaOH and recrystn. from C_6H_6 , cyclopentenylethylmalonic acid is obtained as colorless crystals, m. 107-107.5° (cor.). By heating this acid to about 150-155° under a reflux condenser until most of the CO_2 has been expelled and further heating for a half hr. at 165-170° cyclopentenylbutyric acid b_4 125-6° (cor.) is obtained. These products may be used in the treatment of diseases such as those produced by *B. leprae* and *B. tuberculosis*.

Face cream. JACQUES RISLER. Fr. 632,356, July 21, 1926. Phosphorescent ZnS is added to cream to protect the skin from harmful rays.

"Toilet creams." J. C. and J. FIELD, LTD., AND E. POLAN. Brit. 281,425, Sept. 24, 1926. NH_3 is used with stearic acid and olive oil or other suitable fatty acids and

fats or fatty oils, glycerol and water, to form a cream which is alk. to phenolphthalein.
Disinfecting compositions. A. ABRAHAM. Brit. 281,530, April 19, 1927. Polymerized CH_2O is dissolved in molten thymol and may be mixed with kieselguhr or other fillers.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

The separation of vanadic acid and its salts from vanadium wastes. N. N. EFREMOV AND A. M. ROZENBERG. *J. Russ. Phys.-Chem. Soc.* 59, 689-99 (1927).—The dry residue from the extrn. of Ra from the Fergan ore contains V_2O_5 32.48, V_2O_4 29.63, U_3O_8 5.74, Al 14.01, Pb 8.69 and smaller amts. of Cu, As, Fe, Ni, Si and Ca. The residue is dissolved in HNO_3 (d. 1.24) and concd. on a water bath until samples on cooling show a ppt. of PbCl_2 . V_2O_5 is filtered off while hot and washed with warm H_2O . The filtrate is evapd. and heated to volatilize excess HNO_3 , dissolved in hot H_2O and filtered. The combined residues contg. 93-6% V_2O_5 dissolve in a slight excess of 25% NaOH on heating. After filtering, the soln. is neutralized and boiled with Na_2CO_3 to ppt. $\text{Al}(\text{OH})_3$ and $\text{Pb}_3(\text{VO}_4)_2$. The filtrate is acidified, boiled and an excess of NH_4OH added to remove traces of $\text{Al}(\text{OH})_3$. The final filtrate is boiled and NH_4Cl added, whereupon NH_4VO_3 ppts. The soln. is concd. until on cooling a sample NH_4Cl seps. A little H_2O is added and the concentrate allowed to stand for 24 hrs. The crystals, filtered off, washed with an NH_4Cl soln. and cold H_2O , contain 99.5% NH_4VO_3 and 0.48% SiO_2 . The second acid filtrate contg. U_3O_8 is combined with the ppts. from the NaOH and Na_2CO_3 treatment and boiled with NaOH. The filtrate is discarded, the residue dissolved in HNO_3 and Pb pptd. with H_2SO_4 . The soln. is neutralized and added to boiling Na_2CO_3 to remove Fe, Cu, Ni and Ca. NaOH ppts. $\text{Na}_2\text{U}_2\text{O}_7$ from the filtrate. NaVO_3 remains in soln. and is purified as above; yield 90%. A practically quant. sepn. of V_2O_5 is thus possible on a factory scale without costly app. or reagents.

BASIL C. SOYENKOFF

The synthesis of ammonia with the aid of extreme pressures. GEORGES CLAUDE. *Mon. produits chim.* 9, No. 91, 9-12; No. 92, 6-11 (1926); *Chem. Zentr.* 1927, 1, 641.—Following a crit. historical survey of the work of Ostwald, Haber, Bosch and their collaborators, C. describes his own exptl. work on the synthesis of NH_3 at extremely high pressures and its application on a com. scale. The theoretical principles involved in pressure equil., rate of reaction and work performed in compression are then discussed and the objections to the high pressures used (over 1000 atm.) are pointed out. Expts. in this range of pressures and the yields of NH_3 obtainable under different conditions, which make possible the com. production of liquid NH_3 , are described. The rapid removal of the heat of the reaction is particularly stressed, and the methods developed for solving this problem are described. The construction of the furnaces, the circulation of gases and the production of H_2 by fractional distn. of H_2O and coke-oven gases are discussed. A list of the plants now using the Claude process is appended.

C. C. DAVIS

Synthetic ammonia. P. FIRMIN. *Industrie chimique* 15, 297-302 (1928); cf. C. A. 22, 1017.—A review comparing the different processes in use. P. THOMASSET. *Chem. Met. Eng.* 35, 342-4 (1925).—A general description of an NH_3 oxidation unit for Pb-chamber plants operating with a 9-11% NH_3 , 91-89% air mixt., a Pt gauze catalyst and an Al or Ni heat exchanger. The converter is of the Parsons type using a cylindrical catalyst of 3 or 4 layers of 80-mesh Pt gauze, of 0.003-in. wire, closed at the bottom by a silica disk and suspended at the top from a Ni holder. A 100-ton chamber plant operating on a 3% niter rate uses 1250 lbs. of niter per day which would, by the use of NH_3 oxidation, save from \$2900 to \$4400 per year. This, plus the saving of 60° Bé H_2SO_4 required to generate N oxides from niter, gives a total saving of \$5000-6500 per year. The oxidation unit described can be purchased and installed for \$6500.

J. H. PERRY

Attempts to prepare calcium hydrosilicates. FRITZ KLASSE. *Zement* 17, 2-9, 49-56 (1928).—Using $x\text{Na}_2\text{O} \cdot y\text{SiO}_2$ compds. of the ratios 2:1, 1:1 and 1:2 it was attempted to produce the corresponding Ca silicates in the wet way according to the reaction $\text{Na}_2\text{SiO}_3 + \text{Ca}(\text{NO}_3)_2 \rightarrow \text{CaSiO}_3 + 2\text{NaNO}_3$. Specially prepd. CO_2 -free reagents were used. After mixing under reduced pressure the reaction was brought to equil. by shaking for a week or two. The ppt. formed was sepd. on a Pukall filter, washed with alc. and both ppt. and filtrate were analyzed. The mol. ratio of the $\text{CaO}:\text{SiO}_2$ in the flocculent ppt.

did not vary greatly from 1:1.05 when the true Na_2SiO_3 compn. was used, even though the proportions of Na_2SiO_3 added to $\text{Ca}(\text{NO}_3)_2$ varied widely. The slightly below theoretical content of Ca in the ppt. is attributed to the following hydrolytic reaction: $2\text{CaSiO}_3 + 2\text{H}_2\text{O} \rightleftharpoons \text{Ca}(\text{HSiO}_3)_2 + \text{Ca}(\text{OH})_2$. The acid silicate, if formed, must have a low soly. under the conditions observed. When a Na_2SiO_3 soln. was used which had the compn. $1\text{Na}_2\text{O}:1.7\text{SiO}_2$ the resulting Ca silicate showed an av. mol. ratio of 1:1.73. The alky. of the remaining soln. increased with increasing ppt. Upon ignition the ppts. became insol. and had to be fused in K_2CO_3 for analysis. When Na_2SiO_3 was used the ppt. did not settle out well from the alc. wash. The compn. varied between 1:1.78 and 1:1.93. With Na_2SiO_3 the compn. of the resulting ppt. did not reach $2\text{CaO}:\text{SiO}_2$ but remained near $1.65\text{CaO}:\text{SiO}_2$. The addn. of $\text{Ca}(\text{OH})_2$ to an aq. suspension of freshly pptd. $\text{CaO}:\text{SiO}_2$ enriched the ppt. in CaO until a ratio of 1.2:1 was attained after agitation for 1 week, showing that a strong hydrolyzing tendency exists in all these Ca hydrosilicates. The failure to get higher than 1.5 to 1.76 CaO per SiO_2 mol. in these expts. is explained by the hydrolysis of the dimol. salt under the imposed conditions. H. F. K.

Use of dolomite in the manufacture of sodium chromate. N. F. YUSHKEVICH AND A. L. URAZOV. Institute of Applied Mineralogy and Metallurgy. *J. Chem. Ind. (Moscow)* 4, 387-94 (1927); cf. *C. A.* 21, 2761.—The usual com. process of manuf. of Na_2CrO_4 consists in calcining a mixt. of natural chromite with Na_2CO_3 and CaO at high temp. in an oxidizing atm.: $4\text{FeO} \cdot \text{Cr}_2\text{O}_3 + 8\text{Na}_2\text{CO}_3 + 7\text{O}_2 = 2\text{Fe}_2\text{O}_3 + 8\text{Na}_2\text{CrO}_4 + 8\text{CO}_2$. The purpose of the CaO is to prevent the mixt. from becoming semifluid, which would prevent it from being oxidized by air. The disadvantage of using CaO is that it reacts with chromite to form CaCrO_4 in amts. which may reach up to 10% of the total chromates obtained. CaCrO_4 being but slightly sol. in H_2O , part of it escapes extn. with H_2O , causing a loss of Cr. Having been informed that in the manuf. of chromate in a large German factory CaO is replaced by dolomite, Y. and U. made lab. expts with a natural chromite contg. Cr_2O_3 44.61, Fe_2O_3 24.28, Al_2O_3 9.86, SiO_2 4.04, CaO trace, MgO not detd., H_2O 0.09% and a dolomitic lime contg. CaO 65.04, MgO 29.69, SiO_2 4.19 and $\text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$ 1.03%. The calcined Na_2CO_3 used was 99.85% pure. They used the same proportions as in their expts. on the old process, only replacing lime by dolomitic lime, i. e., chromite 37.85, calcined dolomite 37.85, calcined Na_2CO_3 24.20, all finely pulverized and mixed. At 1050° and at 1160° the speed of oxidation of Cr_2O_3 to CrO_3 is only slightly greater when using dolomitic lime than in the case of CaO, but at 830° , and particularly at 930° , the speed of oxidation is considerably less with dolomitic lime than with CaO. As far as acceleration of the reaction is concerned there is no advantage in replacing CaO by dolomitic lime, but from the point of view of ease of extn. of the chromates obtained the use of dolomitic lime has a considerable advantage over CaO. An investigation of the comparative stability of CaCrO_4 and of MgCrO_4 at high temps. has shown that the former, in the absence of CaO, begins to decompose very slowly at about 930° , whereas in presence of CaO it decomposes rapidly even at 830° . With increase of temp. to 1160° more than half of the total amt. of CaCrO_4 decomposes in 2 hrs., whether CaO is present or not: $4\text{CaCrO}_4 = 4\text{CaO} + 2\text{Cr}_2\text{O}_3 + 3\text{O}_2$. The decompn. of MgCrO_4 , conforming to an analogous equation, is noticeable even at 503° and becomes appreciable in the temp. interval 580 - 650° . Calcination of MgCrO_4 at 650° for 2 hrs., alone or mixed with MgO, decomposes 97.75 to 99.31% of it. Since the pressure of the gases in the factory furnace is 0.1 atm. the decompn. of MgCrO_4 should take place under these conditions at even lower temps. This explains the advantage of using dolomitic lime. The comparatively low CaO content in the dolomitic lime results in the formation of a smaller amt. of CaCrO_4 , and MgCrO_4 is not obtained at all, since it is not stable at the temp. of calcination. It might seem that replacing CaO by MgO instead of by dolomitic lime would be even more advantageous, but expts. show that in this case the Na_2CrO_4 obtained reacts with MgO, forming MgCrO_4 , which decomposes by heat into MgO, Cr_2O_3 and O_2 , and a sort of an equil. is reached when only 73 to 75% of Na_2CrO_4 is formed. It is thus necessary to use either lime or dolomitic lime, and the formation of some CaCrO_4 is unavoidable. Since the soly. of the latter increases considerably with the rise of temp., it is best to extract the chromates from the product of the reaction by boiling H_2O , and even in an autoclave, to increase the % of extd. Cr. BERNARD NELSON

Preparation of sodium formaldehyde-sulfoxylate. N. A. BACH-NIKOLAEVA. *Papers Karpov Chem. Inst. Bach. Memorial Papers* 1927, 92-100.—Under the com. name of Rongalite C $\text{NaHSO}_3 \cdot \text{CH}_2\text{O}$ is widely used in the industry as a reducing agent. The best method of prepn., based on reduction of $\text{NHSO}_3 \cdot \text{CH}_2\text{O} \cdot \text{H}_2\text{O}$ by Zn dust (German patents 165,280, 165,807, 202,242, 222, 195; K. Jellineck "Das Hydrosulfit" 1912;

p. 105), gives unsatisfactory results. The method given in German patent 276,984 (1914) is, on the contrary, very convenient if the following details are observed: A bisulfite soln. contg. 38.8-39.4% NaHSO_3 and 1.1-0.25% Na_2SO_3 and also impurities, chiefly colloidal Fe_2O_3 , is transformed into a soln. contg. 50-65 g. $\text{NaHSO}_3 \cdot \text{CH}_2\text{O}$ per 100 cc. by boiling for a few min. with CH_2O . The latter should be in excess to ppt. Fe_2O_3 , which is removed by filtration. The filtrate is then reduced by Zn sponge: $\text{NaHSO}_3 \cdot \text{CH}_2\text{O} + \text{Zn} + \text{H}_2\text{O} = \text{NaHSO}_2 \cdot \text{CH}_2\text{O} + \text{Zn}(\text{OH})_2$. Zn sponge is prepd. by electrolysis from an alk. bath using a brass sieve as cathode and a sol. Zn anode contained in an asbestos bag serving as a diaphragm. To effect the reduction an excess of sponge is put into the formalite-bisulfite soln. contained in a flask having a reflux condenser, and the mixt. is vigorously stirred and boiled for about 2 to 3 hr. The presence of Fe in the sponge lowers considerably the reducing capacity of Zn sponge, but Cu appears to increase it. Portions of the liquid are removed occasionally to test the progress of the reaction by the iodometric method. Rongalite is titrated in acid soln.: $\text{NaHSO}_2 \cdot \text{CH}_2\text{O} + 4\text{I} + 2\text{H}_2\text{O} = \text{NaHSO}_4 + \text{CH}_2\text{O} + 4\text{HI}$. When the titration is ended the titrated liquid is neutralized by NaHCO_3 and the amt. of non-reacted formalite-bisulfite is titrated, with vigorous stirring: $\text{NaHSO}_2 \cdot \text{CH}_2\text{O} + 2\text{I} + \text{H}_2\text{O} = \text{NaHSO}_4 + \text{CH}_2\text{O} + 4\text{I}$. When the reduction of formalite bisulfite is ended the remaining Zn sponge and $\text{Zn}(\text{OH})_2$ are filtered off by suction and can be used again for the prepn. of Zn sponge. The filtrate contains pure rongalite, which can be obtained as crystals by evapn. *in vacuo*. These crystals, after air drying, contain 95-7% $\text{NaHSO}_2 \cdot \text{CH}_2\text{O} \cdot 0.2\text{H}_2\text{O}$. By recrystg. from H_2O and drying *in vacuo* a 99% product is obtained.

Observations of the phenomena met in obtaining sodium nitrate from caliche. A. PEEFENBERGER AND G. LEIMBACH *Caliche* 9, 485 512(1928).—An examination of prior reports, expressed in various terms, of the soly. and phase relations of the most common components met in extracting caliche, replete with extensible tables and triangular isotherms with varied solid phases. Particular attention is given to the development of insol. Darapskite, $\text{NaNO}_3 \cdot \text{Na}_2\text{SO}_4 \cdot \text{H}_2\text{O}$, in leaching below 68.5°. The quaternary system, NaNO_3 , NaCl , Na_2SO_4 , H_2O , velocity of soln. and of crvstn. of NaNO_3 , NaCl and Na_2SO_4 , velocity of soln. of Darapskite in solns. satd. with Na_2SO_4 and NaCl and cooling of designated solns. are considered in detail. J. H. F.

Preparation of crystallized sodium-chromium alum. E. I. ORLOV, Kharkov Technological Institute. *Ukrainskii Khim. Zhurnal* 3, 115 7(1928).—To obtain Na-Cr alum in cryst. form, hitherto thought to be very difficult, O. phase xylene as reducing agent of $\text{Na}_2\text{Cr}_2\text{O}_7$. 100 g. of xylene were added, in small portions and while stirring, to a sealed flask contg. 300 g. H_2SO_4 , sp. gr. 1.84. The xylene dissolved, forming sulfacids; 295 g. of H_2SO_4 , sp. gr. 1.84, were added, the mixt. was poured into a large porcelain dish contg. 1 l. of H_2O and 375 g. of finely powdered $\text{Na}_2\text{Cr}_2\text{O}_7$ were added in small portions. The reaction takes place at first in the cold and is ended by heating over a free flame, the liquid turning green. The soln. is evapd. to 1339 g. The product, contg. Cr_2O_3 12.97 and SO_3 28.37, is poured into flat porcelain dishes, covered, and left to crystallize at room temp. The crystals obtained are very small, appearing under the microscope as a conglomerate of green, violet and colorless grains. The Na-Cr alum can be recrystd. from H_2O by slow evapn. of satd. solns. It could be used in the tanning industry to replace the more expensive K-Cr alum. B. N.

Sodium and potassium bisulfates. Their use in agriculture. P. WAGUET. *Rev. prod. chim.* 31, 401-3(1928).—The manuf., properties, industrial uses and use in agriculture of these two products are discussed. P. A. THOMASSET

An installation for handling potassium salts. LEVI. *Science ind.* 12, 16-23 (1928).—The total storing capacity of the plant is 200,000 tons; loading is done at the rate of 700 tons, with equipment for simultaneous unloading of 200 tons per hour. Salt in bags is handled by means of special cranes on movable bridges. R. D. RUMBACHER

Making pure tungstic oxide involves many unusual plant problems. W. B. GERO AND C. V. IREDELL. *Chem. Met. Eng.* 35, 412-7(1928).—Description of plant equipment for the manuf. of pure WO_3 from wolframite. The process involves digestion in NaOH soln., pptn. as CaWO_4 , treatment with HCl to form H_2WO_4 , neutralization with NH_3 , and ignition of $(\text{NH}_4)_2\text{WO}_4$ to WO_3 . G. B. TAYLOR

Transformation of zinc slag into pure zinc chloride. N. N. EPREMOV AND A. M. ROZENBERG. *J. Chem. Ind. (Moscow)* 4, 422-4(1927).—Zinc slag is often insol. in HCl on account of contg. up to 20% of Pb, which is apt to form a protective coating on the surface of Zn grains. To transform this waste product into ZnCl_2 , the Pb film is destroyed by an oxidizing calcination at 300-500°. A higher temp. would cause the loss of some Zn as volatile oxide. It is then dissolved in cold HCl (d. 1.12), 1500 cc. per kg. of cal-

cined slag being used. Sand, clay and other earthy materials are allowed to settle for 24 hrs. and the soln. is sepd. by decantation and treated with granular Zn to ppt. Pb, Cu, Sb, etc.

BERNARD NELSON

Chemical treatment of Solikamsk carnallite. N. N. EFREMOV AND A. A. VESKLOVSKI. *Northern Chem. Trust. J. Chem. Ind. (Moscow)* 4, 489-95 (1927).—The av. compn. of Solikamsk carnallite is: MgCl_2 25.88, KCl 23.55, H_2O (combined) 28.03, NaCl 20.60, MgSO_4 none, CaSO_4 1.46, hygroscopic H_2O none. The main difference between Solikamsk and Stassfurth carnallites, which simplifies the treatment of the former, is the absence of MgSO_4 . In the case of Stassfurth carnallite, to sep. MgCl_2 and KCl by crystn. treatment with H_2O at $120-135^\circ$ under pressure is necessary. Solikamsk carnallite gives very good results with cold H_2O treatments. This investigation is still in a preliminary stage.

BERNARD NELSON

Chemical treatment of Solikamsk sylvite. F. F. VOLF AND V. S. YATLOV. *Northern Chem. Trust. J. Chem. Ind. (Moscow)* 4, 485-9 (1927).—Solikamsk sylvite has the following compn.: sylvite (KCl) 18.45-44.14, carnallite ($\text{KCl} \cdot \text{MgCl}_2 \cdot 6\text{H}_2\text{O}$) none, MgCl_2 0.0-0.28, kieserite ($\text{MgSO}_4 \cdot \text{H}_2\text{O}$) none, anhydrite (CaSO_4) 0.92-3.70, halite (NaCl) 53.1-78.23, H_2O -insol. 0.27-2.16. The H_2O -insol. contains SiO_2 25.29, Fe_2O_3 3.27, Al_2O_3 3.86, Cu_2O 25.10, MgO 2.18, SO_3 24.65, undetd. 9.74, loss on ignition 5.91. It has been proposed to use Solikamsk sylvite for the manuf. of fertilizers. A high-grade fertilizing salt contg. 82% KCl can be obtained from a sylvite contg. 18.45% KCl by a single soln. followed by decantation and crystn. It is more profitable to use it for the manuf. of pure KCl as Stassfurth sylvite is used in Germany. For this Solikamsk sylvite has the advantage over Stassfurth sylvite in contg. no kieserite, the latter hindering crystn. of pure KCl . If Solikamsk sylvite is crystd. with stirring, and the crystals are drained on a vacuum filter without washing, a high quality salt contg. 99.20% KCl and 0.72% NaCl is obtained.

BERNARD NELSON

Catalytic refining of bromine. P. T. DANILCHENKO AND M. I. RAVICH. *J. Russ. Phys. Chem. Soc.* 59, 953-68 (1927).—Crude Br_2 was passed at 115° over 6.5 g charcoal contg. 9.16% Fe_2O_3 , prepd. by impregnating with $\text{Fe}(\text{NO}_3)_3$ and heating to redness in the absence of air for 2 hrs. The purified product contained 0.05% Cl_2 . The catalyst did not lose its activity after 700 g. of Br_2 had passed through. Al_2O_3 on charcoal is equally effective at 165° ; charcoal alone is much less so. The % of Cl_2 in the purified Br_2 does not depend upon its original amt. nor upon org. substances. The org. impurities are partly removed, although the catalyst does not show a commensurate gain in wt. Among the possible reactions are the hydrolysis of Cl_2 to HCl and O_2 , the action of Cl_2 on HBr , CBr_4 and CHCl_3 . The purified product contained about 0.62% HCl , a gain of 0.52%, which accounted for the disappearance of 57% Cl_2 , the remainder being used to displace Br_2 from the org. compds., which thus facilitate the removal of Cl_2 .

BASIL C. SOYENKOFF

Extraction of bromine from aqueous salt solutions. O. YU. MAGIDSON AND R. A. KONOVALA. *J. Chem. Ind. (Moscow)* 4, 153-4 (1927).—Cf. K. I. Sheidt, *C. A.* 22, 3022. To sep. Br from tribromophenol Sheidt boiled the latter with dil. HNO_3 , then distd. the Br; pure picric acid was obtained at a 90% yield whereas almost 98% Br was generated. M. and K. found that dil. or strong HNO_3 gave neither picric acid nor Br in large amts. To recover all the Br the tribromophenol would have to be fused with an alkali and thus completely destroyed. This expensive operation would make the sepn. of Br from aq. solns. as tribromophenol uneconomical.

The volumetric relations in the manufacture of hydrogen from carbon monoxide and water. ROBERT NITZSCHMANN. *Chem. App.* 15, 159-61 (1928).—Mathematical.

J. H. MOORE

A world view of nitrogen economics. JULIUS BUEB. *Chem. Met. Eng.* 35, 348-9 (1928).—An abbreviated form of B.'s paper written for the International Nitrogen Conference on the S. S. Lützow's Adriatic cruise. The assistance of governments should include cheap freight rates on all raw materials, abolition of all tariff duties, and support of suitable credit institutions. Vital statistics of the N industry since 1924 are included.

J. H. PERRY

The nitrogen problem in Brazil. JEAN P. LEHALLEUR. *Chimica industria* 1, 340-6 (1926).—An address. Brazil possesses no commercially exploitable nitrate deposits. The requirements of agriculture and national defense would best be met by synthetic NH_4NO_3 . The various processes are reviewed.

R. D. BUMBACHER

The "denitrification" of mother liquor. B. DIAZ OSSO. *Calcice* 9, 529 (1928).—This term, used by Donnan in his 1919 report, means such recovery of the residual, dissolved NaNO_3 that the mother liquor need not be reused for leaching. O. points out that the use of fresh H_2O increases the NaNO_3 extraction but gives difficulties in so

treating the mother liquor. Air agitation and evapn. in open tanks require careful control. Boiling at 110° removes sulfate and chloride by pptn., but using double effect evaporators has not proved economical. Removal of NaNO_3 from a Shanks process mother liquor by cooling tends to ppt. also Darapskite, $\text{NaNO}_3 \cdot \text{Na}_2\text{SO}_4 \cdot \text{H}_2\text{O}$. Guggenheim Brothers (Chilean patent 4594) cool to 2° a liquor satd. at 35° . It also has been suggested to mix 2 salt solns. to obtain a metastable condition of one salt, to be pptd. by seeding. Complete evapn. of the Shanks process mother liquor at atm. temp. yields 630 kg. of sol. salts per cu. m. contg. 69% nitrate. J. HOWARD FLINT

Chemical engineering may revive sublimation of sulfur. E. F. WHITE; *Chem. Met. Eng.* **35**, 355-6 (1928).—Flowers of S are preferred to the ground crude material in many industries such as rubber vulcanization, insecticides, and soil revivification. The app. developed consists of a retort and melting pan fired by a furnace contg. an air preheater. The S from the melting pan flows through a liquid seal into the retort where a const. level is maintained during the S vaporization. Flue gas from the burner heats the retort, the melting pan and the air. Three cu. ft. of the inert gas is required per lb. S, and this circulating atm. is handled by a small blower at $1\frac{1}{4}$ in. H_2O pressure. The inert gas is injected into the retort at 5 in. H_2O pressure and into the neck connecting retort and chamber. The gas leaving the chamber passes through a dust collector, through a H_2O -removal app. and back to the blower. The chamber temp. is 105°F and a volume of 10 cu. ft. per lb. S per hr. was found to be ample. The S flowers produced averaged over 97% through 200 mesh. Maintenance and depreciation are smaller; the hazard is less than in grinding, and the power costs are less. J. H. PERRY

The rotary kiln in the lime industry. T. KLEBE; *Forind-Ztg.* **51**, 1002-4 (1927). The use of rotary kilns in the lime industry is comparatively new but appears promising. H. G. SCHRECHT

Deterioration of steels in the synthesis of ammonia (Vander, *et al.* 9. Alkali, etc., works in Scotland (Young) 13.

Nitric acid. NORSK HYDRO-ELEKTRISK KVAELSTOFARBEIDNING. Brit. 281,642, Dec. 6, 1926. An app. is described in which continuous concn. of HNO_3 by boiling and rectification is carried out under reduced pressure. Dil. HNO_3 is introduced through a sealing tube into the upper part of a rectification column connected to condensers and a source of vacuum. Acid from the bottom of the column passes through a series of boilers and is withdrawn when it becomes sufficiently concd.

Sulfuric acid. H. PETERSEN. Brit. 281,551, June 7, 1927. In the use of tower-packed with small grains of quartzite, denitration is effected by cold sulfurous gases in one of the towers. The gases from the roasting oven are cooled by use in an app. for concg. H_2SO_4 and may be passed through cooling or condensing app. to a p. acid contg. water before use in the denitrating tower.

Sulfuric acid. SOC. GENERALE METALLURGIQUE DE HOBOKEN. Brit. 281,510, Feb. 19, 1927. Reaction chambers packed with small pieces of acid-resisting material (in chambers of not more than 50 sq. m. cross section) are used in producing H_2SO_4 as described in Brit. 249,914 (*C. A.* **21**, 991).

Recovering carbon dioxide. I. G. FARBENFABR. A. G. Pat. 622,664, April 12, 1927. See Brit. 271,852 (*C. A.* **22**, 1637).

Alkali compounds. ALBERT F. MEYERHOFFER. Fr. 632,890, April 14, 1927. Alkali compds. are formed from alkali salts and alk. earth compds., the reaction being carried out in a very short time and the lyes being sep'd. as soon as the reaction slackens.

Alkali metal compounds from silicates. THOMAS A. EDISON (to Thomas A. Edison, Inc.). U. S. 1,678,246, July 24. Finely divided silicate material such as feldspar or spodumene is treated with water and an alk. earth hydroxide such as $\text{Ca}(\text{OH})_2$ and heated to free the alkali metal from the silicate; the resultant mass is subjected to a head of liquid sufficient to displace the water and sol. salts. An app. is described.

Alkali metal cyanides. ROBERT W. POINDEXTER, JR., and PAUL T. DOLLEY (to Calif. Cyanide Co.). U. S. 1,677,986, July 24. An app. is specified comprising a converter for holding a fused alkali metal carbonate mixt. and a Cu tube for introducing HCN ; this tube has a protecting sheath of material such as Fe which is not attacked by fused alkali metal cyanide and is provided with a protecting tip composed of material

such as C which neither decomposes HCN nor is substantially attacked by fused alkali metal cyanide. Other structural features are described. Cf. *C. A.* **21**, 1873.

Cyanamides. N. CARO and A. R. FRANK. Brit. 281,610, Dec. 2, 1926. In prep. Ca or Mg cyanamides as described in Brit. 279,811 (*C. A.* **22**, 3024), NH_3 gas is passed over the heated carbonate at increased velocity and lower temps. may be used.

Cyanamides. STICKSTOFFWERKE GES. (to N. Caro and A. R. Frank). Brit. 281,611, Dec. 2, 1926. Cyanamides of Mg or other alk. earth metals are prepd. by treating oxides or compds. such as formates or carbonates which form oxides on heating with gaseous mixts. such as NH_3 and CO which tend to form HCN. The treatment is effected at $400\text{--}850^\circ$ and at either ordinary or increased pressure. Presence of H_2O increases formation of cyanamide. Presence of Fe is avoided and the app. used may be formed of ceramic material or Zn, and Fe carbonyl is eliminated from the gases. H_2S or CS_2 may be added to the gases or Ca sulfide or CaSO_4 to the solid materials as the S apparently serves to prevent decomp. of the product by metals present.

Anhydrous chlorides. I. G. FARBENIND. A. G. Fr. 632,503, Apr. 8, 1927. Anhydrous chlorides of Mg, Ca, Zn, Li or Ce are formed by causing the corresponding oxides as a suspension in the melted chloride or in melted mixts. of other chlorides to flow down a tower, up which a chlorinating gas such as HCl or phosgene is ascending. Carbon may be added to the oxide and the tower may contain coke.

Metallic chlorides. I. G. FARBENIND. A. G. Brit. 281,191, Jan. 7, 1927. A mixt. of gases contg. H, CO and Cl_2 , e. g., a mixt. of water gas and Cl_2 , is used for treating kaolin, chrom. Fe ore or other oxide contg. substances (suitably in a continuous manner in a rotary furnace) to form metal chlorides such as those of Al or Fe, which may be sepd. from associated HCl by dec. pptn. or partly by water-cooled condensers and further by dec. pptn. The HCl may be washed with coned. HCl to free it from metal chlorides and then absorbed in water. (*C. A.* **22**, 2444)

Alumina. T. R. K. HAGLUND. Can. 282,063, July 31, 1928. Al_2O_3 is manufd. by forming, on refining Al_2O_3 contg. raw material, a melt contg. both fused Al_2O_3 and Al_2S_3 , decomp. the sulfide by subjecting the melt to such incomplete oxidation that at least a part of the S is sepd. out as free S and carrying on the oxidation at such temp. that Al_2O_3 formed does not lose its ability to absorb H_2O but still high enough to enable free S to distil off, thereupon treating the oxidized melt with H_2O and sepg. the fused Al_2O_3 out of the treated melt.

Refining alumina. T. R. K. HAGLUND. Can. 282,064, July 31, 1928. Raw materials contg. Al_2O_3 are refined by first forming a slag contg. both Al_2S_3 and fused Al_2O_3 , decomp. Al_2S_3 with H_2O and sepg. out the fused Al_2O_3 and decomp. impurities of Fe sulfides by treating the residue with a gaseous Cl combination as HCl gas in presence of H_2O vapor and removing formed chloride combinations.

Ammonium chloride crystals. JOSEPH WILLIAM MOORE and WILFRED GUSTAV FORACK (to Imperial Chemical Industries, Ltd.). Can. 281,984, July 24, 1928. Gaseous NH_3 is allowed to react with gaseous HCl under such thermal conditions (with regard to velocity or thermal insulation) that a solid is deposited at 300° and produces a mass of tough fibrous crystals practically chemically pure.

Apparatus for producing ammonium sulfate crystals from ammonia and sulfuric acid or for similar processes. E. M. WEYMAN and R. P. WALLIS (representing G. Weyman). Brit. 281,165, Nov. 18, 1926.

Barium hydroxide. SOC. FRANÇAISE SUCRATERIES (Brevets et procédés Deguide). Fr. 633,368, Apr. 26. $\text{Ba}(\text{OH})_2$ is formed by attacking at about 1500° natural BaSO_4 with silica and grinding the product in the presence of H_2O . As by-products HCl and caustic alkalies and carbonates are prepd.

Borax. THOMAS M. CRYMER (to Pacific Coast Borax Co.). U. S. 1,678,381, July 24. In producing commercial borax from natural $\text{Na}_2\text{O} \cdot 2\text{B}_2\text{O}_3 \cdot 4\text{H}_2\text{O}$ the material is heated to about 115° to render it less resistant to soln. in water and is then dissolved and crystd.

Chromyl chloride. PERMUTIT. A. G. Fr. 633,517, April 28, 1927. See Brit. 270,711 (*C. A.* **22**, 1597).

Hexamethylenetetramine and ammonium chloride. SOC. S. KARPEN & BROS. Fr. 633,262, Apr. 23, 1927. To sep. $(\text{CH}_2)_6\text{N}_4$ from NH_4Cl formed in the reaction between CH_2Cl_2 and NH_3 , e. g., as described in Fr. 584,972, use is made of the fact that $(\text{CH}_2)_6\text{N}_4$ is less sol. in H_2O surcharged with NH_3 gas, whereas the soly. of NH_4Cl is slightly increased.

Hydrogen and carbon monoxide. MARIA CASALE-SACCHI. Fr. 632,660, April 12, 1927. In a process for prep. a mixt. of H and CO free from CH_4 from hydrocarbons or gaseous mixts. contg. hydrocarbons, oxygen and water, the reaction is carried out at a temp. above 1000° , with excess of H_2O , and at a reduced pressure.

Iron phosphates. PARKER RUST-PROOF CO. Fr. 632,340, April 7, 1927. Strongly acid orthophosphates of iron are made by projecting a concd. soln. of H_3PO_4 in a divided state on to particles of iron heated to 100° and in a gas at the same temp. They are used specially for preventing the rusting of iron.

Phosphates. PARKER RUST-PROOF CO. Fr. 632,341, April 7, 1927. A mixt. of dihydrogen phosphates of Fe and Mn is made by dissolving Fe and Mn in excess of phosphoric acid, crystallizing and drying the crystals under oxidizing conditions. It is used for preventing the rusting of iron.

Silicates. FERDINAND RICARD. Fr. 632,509, April 9, 1927. Na_2SiO_3 is formed by adding a powdered SiO_2 mineral to NaOH, which is treated with CO_2 to satn., giving a ppt. of SiO_2 , or the soln. of Na_2SiO_3 is treated with slaked lime to give $CaSiO_3$, the soln. in each step being used again in the process.

Sodium hypochlorite. MALCOLM P. APPLEBEY and CHARLES CARTER. Fr. 632,187, Apr. 4, 1927. A solid, drv and stable prepn. of NaOCl is obtained by admixture of a strong soln. or the melted crystals with wholly or partially dehydrated Na_2PO_4 or salts forming Na_2PO_4 .

Sodium sulfide. ALFRED H. WHITE (to John E. Alexander and Edward G. Goodell, Trustees for Falls Mfg. Co.). Can. 282,189, July 31, 1928. Na_2S is formed from material contg. Na_2SO_4 by heating a mixt. of such material, CaO and C to about 700° to form Na_2S and $CaCO_3$.

Zinc white. JOSEPH-MARCEL-HENRI CORNILLAT. Fr. 632,235, July 15, 1926. An app. for producing zinc white is described in which a slab of zinc is put into a furnace heated to about 1200° .

Gypsum. ARTHUR ANKER. Fr. 633,310, April 25, 1927. An app. is described for drying and reheating gypsum or the like, in which the material descends mechanically on plates in an annular space having a cylinder inside and an annular space outside for a heating fluid.

Sulfates and sulfur. CHARLES HARNIST. Fr. 633,105, April 25, 1925. Sulfates and S are obtained by heating under pressure the salts formed by the action of SO_2 in the presence of H_2O and H_2S on alkali metal, or ammonium compds. such as hydrates, carbonates or sulfides. Thus, the salts obtained when a gas contg. NH_3 and H_2S , such as the gas from coke furnaces, is led through a water saturator through which SO_2 is also passed, are so treated.

Purifying sulfur. W. BLYTHE & CO., LTD., W. H. BENTLEY and B. CATLOW. Brit. 281,133, Feb. 12, 1927. S. contg. bituminous impurities is distd. in the presence of non-volatile solid adsorbents or materials such as $CaSO_4$, bone ash, Na_2SO_4 , fine sand, kieselguhr, silica gel, pptd. silica, powdered charcoal and active C. The distn. may be carried out in a continuous manner.

Hydrogen from methane. I. G. FARBENIND. A.-G. Fr. 632,861, April 15, 1927. See Brit. 267,535 (C. A. 22, 1219).

Lithium. METALLBANK UND METALLURGISCHE GESELLSCHAFT AKTIENGESELLSCHAFT. Fr. 632,225, April 6, 1927. Li is obtained from its minerals by heating them with alkali salts to a temp. of $800-950^\circ$ in a tubular revolving furnace.

Recovering phosphorus from gases. I. G. FARBENIND. A.-G. Fr. 632,656, April 12, 1927. See Brit. 279,710 (C. A. 22, 3025).

Aldehyde condensation product. GEORGE S. SHAW (to The Can. Electro Products Co., Ltd.). Can. 281,951, July 24, 1928. An AcH condensation product is made by treating the aldehyde at 10° to 15° with 2.2 g. of alk. condensing agent per kg. of finished product, the condensing agent being in soln. of 10% concn., and then treating the resulting mass at 20° to 45° , with approx. double the amt. of the same condensing agent in soln. of approx. 20% concn.

Condensation products. PAUL HALLER and HANS KAPPELER. Can. 282,036, July 31, 1928. Aromatic amines reacting in the presence of strong mineral acids (HCl) with H_2CO form solid jellies which on treatment with inorg. or org. bases or basic, neutral or acid salts or weak acids on drying form valuable artificial masses of wood-like, bony or horny appearance.

Condensation products of phenols and aldehydes. LEONHARD DEUTSCH and ISAK THORN (to Selden Co.). U. S. 1,678,107, July 24. Light colored and color-fast, hard, infusible and insol. condensation products are formed from phenols and aldehydes such as PhOH and CH_2O by effecting condensation with an alkali and adding H_3BO_3 to the reaction product. U. S. 1,678,108 specifies molding and hardening fusible condensation products of phenols and aldehydes in an open-bottomed mold while supported on a molten alloy of low m. p. or other suitable material of higher sp. gr. than the condensation product.

Condensation product of urea, formaldehyde and a phenol. CHARLES O. TERWILLIGER (to Fritz v. Briesen). U. S. 1,678,024, July 24. In the reaction mixt. used, the ratio of 40% CH_2O soln. to urea is less than 2.5:1. Condensation is effected by heating and the product is highly resistant to water.

Hydrogenating phenol-ketone condensation products. SCHERING-KAHLBAUM A.-G. (formerly Chem. Fabrik auf Aktien vorm. E. Schering). Brit. 280,956, Nov. 22, 1926. Thymol, its isomers or homologs and their hexahydro compds. are made by hydrogenating etheric condensation products such as those from *m*-cresol and acetone or *p*-cresol and acetone.

"Artificial horn." A. JAGER and HEROLD A.-G. Brit. 281,537, May 17, 1927. PhOH 1, together with a 30% aq. CH_2O soln. 2–3.0 parts and an alkali salt of a fatty acid such as Na stearate in a quantity corresponding to at least 0.035 part of NaOH, are heated to about 70° for about 90 min. and the product is dehydrated *in vacuo* until the temp., after first falling, has again risen to about 65°. Salicylic acid 1.8 mols. for each mol. of alkali in the mixt. is then added and the mixt. is further dehydrated and then hardened by heating in open molds. Substances such as castor oil or glycerol also may be added.

Horn-like substances. DEUTSCHE KUNSTHORN G.M.B.H. Fr. 632,471, Oct. 27, 1926. Addn. to 611,342. In the prepn. of horn-like substances from albuminoids, the plastic mass is allowed to stand for some time after molding before the usual drying.

Substitute for horn, ebonite, etc. HEINO LIPPMANN. Fr. 633,591, April 29, 1927. A substitute for horn, ebonite, celluloid, etc., is made from scraps of paper or cloth mixed with a binder such as gum, resin or glue. It can be molded under pressure and heat. Other substances may be added according to the particular application of the substitute.

Treating bauxites with sulfuric acid. FRANCOIS TRAWINSKI. Fr. 633,199, April 4, 1927. In treating bauxites the bauxite in H_2O is added to concd. H_2SO_4 , thus using the heat of hydration, the heat of neutralization and of soln. of the $\text{Al}_2(\text{SO}_4)_3$.

Plastic compositions. O. MANFRED. Brit. 281,223, Nov. 26, 1926. Before or during plastification, casein, albumin or similar materials are admixed with substances which increase plasticity and release aldehydes, e. g., with aldehyde-ammonia combinations, formaldehyde-aniline or toluidine, mono- or dianhydro formaldehyde, phenylenediamine, ethyldecaniline, furfuramide, aldehyde-amino polymerization products or reaction products of aldehydes with aldehyde-amino compds. or thio compds. of similar nature, formates or methylamines or the like together with an oxidizing agent. Rubber or compds. such as isoprene, erythrene and amino acids preferably also are added and latex stabilized with a protective colloid may be sprayed into the mass.

Plastic compositions. SLUR TECHN. & CHEM. PRODUKTE GES. M.B.H. and ISAK THORN. Fr. 632,526, Apr. 9, 1927. A plastic compn. is made by mixing flour or pure starch with urea or the S. derivs. of carbonic acid or condensation products of urea and CH_2O or substances yielding CH_2O .

Plastic material. CHARLES CACHON. Fr. 633,626, April 30, 1927. A plastic material suitable for the manuf. of fancy goods is made by uniting one or several thicknesses of cloth, preferably artificial silk, between two sheets of plastic material such as celluloid or cellulose acetate, by means of an appropriate solvent which will superficially dissolve the sheets and as much as possible of the cloth.

Molding aluminous compositions. FELIX HOMBERG (to American Nuplax Corp.). U. S. 1,678,117, July 24. Cr-lined metal molds are used.

Adhesives for catching insects. V. SCHOLZ and B. EIBES. Brit. 281,068, Nov. 1, 1926. Material such as acetylcellulose, nitrocellulose or celluloid waste or decamphorated celluloid is dissolved in a solvent such as acetone or EtOAc together with a large proportion of oil such as castor oil, oxidized castor oil, oxidized linseed oil or other similar oil, with or without various other substances.

Nascent gases. SOC. INTERN. PROCÉDÉS PRUDHOMME. Fr. 632,379, July 23, 1926. To render gases such as H highly reactive, they are passed through metals or metallic oxides capable of transforming them from the mol. to the atomic state. The H may be used to ext. a metal from its compds., for the synthesis of NH_3 and for the regeneration of purifiers.

Rare gases. JEAN B. J. M. ABADIE. Fr. 633,394, Aug. 14, 1926. Rare gases are purified by alkali or alk. earth metals such as Ca which forms one or both electrodes in a tube, the metal being heated so as to have different temp. zones.

Drying gases. I. G. FARBENIND. A.-G. Fr. 632,311, April 6, 1927. Phosphoric acid contg. P_2O_5 in soln. is used as a drying agent for gases.

Separating acetylene from other gases. I. G. FARBENIND. A.-G. Brit. 280,885,

Nov. 16, 1926. The gas is washed with water or an aq. soln. under high pressure, *e. g.*, 5-25 atm., to effect selective soln. of C_2H_2 and sepn. from other gases such as CH_4 and H_2 . Na_2CO_3 , $NaCl$, $NaNO_3$ or Na_2SO_4 may be added to lessen the soly. of other gases. Separation of hydrogen from mixtures of gases. HENRI M. R. BARTOT. Fr. 632,337, April 7, 1927. See Brit. 251,988 (*C. A.* 21, 1526).

Nitrogen-hydrogen mixture. FRANS G. LILJENROTH. U. S. 1,678,518, July 24. In producing a definitely proportioned mixt. of H and N suitable for NH_3 synthesis, water is electrolytically decomposed and the O obtained is used together with steam and atm. air for continuously operating a water-gas generator; the CO of the water gas generated is converted by means of steam into CO_2 while setting H free, the CO_2 is removed and the remaining gas is mixed with the H obtained in the electrolysis.

Catalysts. I. G. FARBERMIND. A.-G. Brit. 281,218, Nov. 27, 1926. Hydrogenation-promoting metals such as Ni, Cu and Co are sepd. in finely divided form from aq. solns. of their salts by the use of Fe, Zn and Al (which may be effected in the presence of a non-metallic carrier such as kieselguhr, silica gel or charcoal) and the catalysts thus prepd. may be used in the hydrogenation of aromatic hydrocarbons or their derivs. such as toluene or phenol, in the hydrogenation of unsatd. compds. such as cinnamic acid or fats in the production of alcs. from aldehydes and ketones, conversion of quinones to hydroquinones, and in reduction of nitriles, nitro, azoxy, azo and hydrazo compds. to the corresponding amines (these reactions may be effected in the liquid phase and at comparatively low temps.). If the soln. from which the catalyst is prepd. is alk. the oxide of the more electropositive element is deposited and serves as an activator. The catalyst may be dried *in vacuo* or in a current of H before use.

Revivifying catalysts. ALPHONS O. JAEGER (to The Selden Co.). U. S. 1,678,626, July 24. In reviving catalysts such as V catalysts used for oxidizing aromatic hydrocarbons which are not injured by oxidizing agents, an inorg. peroxide such as H_2O_2 is used for treating the catalyst. U. S. 1,678,627 specifies treating catalysts such as those contg. V compds. with SO_3 or other "acidogen" which is volatile at a temp. below redness and does not leave a residue non-volatile upon treatment with O-contg. gases at elevated temps. Steam also may be used.

Catalytic gels. E. B. MILLER and G. C. CONNOLLY (to Silica Gel Corporation). Brit. 280,939, Nov. 19, 1926. A hydrogel such as that of silica or oxides of W, Sn or Al is treated with a soln. of a catalyst-yielding salt such as a salt of Cu, Fe, Al, Mn, Ni, Ag or Pt, water is removed from the hydrogel and the material is heated to decompose the impregnating salt.

Catalytic oxidation and dehydrogenation of organic compounds. A. O. JAEGER (to Selden Co.). Brit. 281,307, Nov. 26, 1926. Catalysts are used which contain 2-component zeolites obtained by reaction of a silicate with one or more "metallates" (tungstates, chromates, uranates, cerates, etc.) or one or more metal salts. An extremely large number of catalytic materials and processes in which they may possibly be employed are mentioned.

Agglomerants. RENÉ A. L. VOLET. Fr. 633,537, Apr. 28, 1927. Synthetic resins such as "bakelite" or "thiolite" are used as binding agents in making articles such as bushes or linings or dynamo brushes from substances such as graphite.

Agglomerant for powdered material. PAUL GONTIHR. Fr. 633,425, Aug. 23, 1926. Substances such as sand, SiO_2 , Al_2O_3 , clay, etc., are agglomerated by a mixt. of an acid and a chloride or a silicate, *e. g.*, phosphoric acid with $MgCl_2$ or $ZnCl_2$ or K silicate, or silicic acid with $AlCl_3$.

Hydrogenation of liquids or semi-liquids. GEORGES R. SCHUELER. Fr. 633,486, April 27, 1927. The hydrogenation catalysts are built up of a number of perforated disks, or plate-like units of interlaced wire or rods, preferably of Ni, and they may be combined on a central perforated tube. They may be corrugated or have indentations to keep them sep. The units are reactivated electrolytically, being suspended in a bath alternately with cathode plates.

Colloids. BOUTEILLE. Fr. 632,357, July 21, 1926. Colloid emulsions, particularly those to be used as conductors of heat or electricity, are stabilized by introducing one or several secondary emulsions not combining with the principal emulsion. A colloidal emulsion of C is obtained by the decompn. of org. matter by H_2SO_4 , H_3PO_4 or electrolysis.

Medium for mounting microscopic preparations. MARC-EMMANUEL-VALENTIN RONDEAU DU NOYER and HENRI BARRAL. Fr. 632,519, Apr. 9, 1927. A medium which is not affected by dampness and does not decolor the preps. is obtained by dissolving a resin in alc. and distg. in the presence of benzene or other liquid preferably at 100° .

Corrosion retarder. WALTER T. SCHREIBER (to U. S. Industrial Alc. Co.). Can. 282,175, July 31, 1928. Corrosion is inhibited on the metallic containers used to store or transport alcs. of the paraffin series that are sol. in H_2O by incorporating soaps sol. in the alc., preferably sol. alk. soaps formed from the higher fatty acids in the proportions of 2 lbs. soap to 100 gals. of the liquid.

Coating pipes or other articles with asphalt or similar rust-preventive material. E. HIMSTEDT and E. DRESCHER (to Vereinigte Stahlwerke A.-G.). Brit. 281,626, Nov. 30, 1926. Mech. features.

Gun-cleaning compound. JOSEF WAGNER. Can. 282,110, July 21, 1928. A gun-cleaning compd. contains 81.5 g. mineral oil, 15 g. alc. oleic acid alkali and 3.5 g. ethyl lactate.

Furniture polish. WILLIAM RICHTER and CARL BOUMBERGER. Can. 281,883, July 24, 1928. Furniture polish contains $18\frac{1}{2}$ oz. light separator oil, $18\frac{1}{2}$ oz. turpentine, $18\frac{1}{2}$ oz. white wine vinegar, 8 oz. beef gall, $2\frac{3}{4}$ oz. copper soln., 4 oz. butter of antimony and $57\frac{1}{4}$ oz. distd. water.

Adsorbent for water vapor. E. B. MILLER and G. C. CONNOLLY (to Silica Gel Corporation). Brit. 280,934, Nov. 19, 1926. A solid porous gel (preferably silica but possibly also oxide of W, Ti, Sn or Al) capable of absorbing at least 10% by wt. of water vapor at 30° and 22 mm. Hg partial pressure (and suitable for use in refrigerating app.) is impregnated with a dehydrating substance, e. g., H_2SO_4 , HPO_3 , $CuSO_4$, $Al_2(SO_4)_3$ or $MgSO_4$.

Rendering porous bodies impervious to liquids. RENÉ OPPENHEIM (to Soc. anon. le carbone). U. S. 1,678,405, July 24. Porous bodies, such as those formed of charcoal, which may be used as electrodes of batteries, electrolyzers or accumulators are provided with a strongly adhering sheath of air or other gas prior to use, e. g., by heating with H_2O and treating with an air current while hot.

Leak-stopping composition. GEORGE I. RAY (to The Radiator Specialty Co.). Can. 282,365, Aug. 7, 1928. A leak-stopping compn. contains a mixt. of Al, flaxseed meal, S and soap. Cf. C. A. 22, 485.

Revivifying spent decolorizing material. OSCAR L. BARNEBEY. U. S. 1,677,947, July 24. Paper pulp or other cellulose fiber is mixed with decolorizing material such as C which may have been used for treating sugar solns. and the mixt. is charred and activated with steam at 700 – 1100° .

Impregnated sheet material. GEORGE L. PREBLE (to Preble Box Toe Co.). U. S. 1,678,021, July 24. A material suitable for making box toes, etc., is prepd. by treating fibrous material such as woven fabric with a soln. of celluloid or similar substance and with a comminuted absorptive substance such as plaster of Paris and then partially drying, compacting and further drying the material in sheet form.

Free-flowing salt fused into globules and special package for dispensing. CARL E. MENSING and ROY E. WILEY. U. S. 1,678,154, July 24.

Preparing steel printing surfaces by carbonizing and etching. HELENA S. SADTLER. U. S. 1,678,231, July 24.

Portable vertical lime kiln with superposed detachable sections. T. DAND. Brit. 281,460, Nov. 10, 1926.

Removing scale from iron sulfate reservoirs. ABEL GASQUET and ARMAND BACQUÉ. Fr. 632,753, Apr. 13, 1927. To remove scale from cylindrical reservoirs used for iron sulfate liquors it is reduced to powder by the ends of branches of chain on a central rotating axle.

Photo-mechanical printing surfaces. T. E. RICHARDS. Brit. 280,958, Nov. 22, 1926. A litho stone or plate, preferably a grained metal plate, is rinsed with HNO_3 , washed and sensitized with a dichromated fish glue compn. contg. also ferric NH_4 citrate and NH_4 . The plate is exposed through a halftone negative or positive, the exposed colloid is dissolved off and the plate is coated with a compn. formed from asphaltum 1 lb., turpentine 1 gal., a soln. of transfer ink 0.5 lb. in turpentine 1 qt., elbagreen oil 1 dram and oleic acid 1 dram. The coated plate is immersed in water, the coating over the exposed dichromated glue is brushed away and the glue itself is removed with H_3PO_4 ; the plate is then washed, cleaned, heated to about 120° and after cooling is treated with gum arabic soln.

Wadding for use on metals. HENRI É. KELLER. Fr. 333,174, Aug. 12, 1926. Wadding is soaked in "Kidur" made by mixing white spirit with oleic acid and adding finely powdered silica, then liquid NH_3 and more white spirit and finally $AmOAc$.

Carbonization of algae. GEORGES J. B. CHAMAGNE. Fr. 633,167, Aug. 11, 1926. A furnace is described for the carbonization of marine algae with a view to recovering K salts, I and Br. Fr. 633,168 describes further improvements.

Insect-proof composition. SYDNEY W. KENDALL. Can. 282,081, July 31, 1928. A compn. comprising a rare element as a base radical (*viz.*, Th, Ti, Ce, La, Di, Yt, Ti, Zr and U), and as an acid radical a higher org. acid (fatty, oleic, linoleic, linolenic, clupanodonic, abietic, cocceric, ricinoleic, dihydroxystearic, jpanic, chaulmoogric, resin or gum acid series) and a varnish for use in protecting cellulosic, animal and other substances against insects, animals, vegetation and organisms. Cf. C. A. 21, 656.

Low-temperature charge for fire extinguisher. CHARLES A. THOMAS and CARROLL A. HOCHWALT. Can. 282,204, Aug. 7, 1928. A charge for fire extinguishers comprises 3 normally sepd. portions, a compd. contg. a sulfonic acid radical or halogenated sulfonic acid (as $\text{CH}_2\text{SO}_2(\text{OH})\text{COOH}$, $\text{C}_6\text{H}_5\text{SO}_2\text{OH}$, FSO_2OH), the second contg. a carbonate (as NaHCO_3) and a third a water soln. of CaCl_2 .

Fire extinguisher. CHARLES A. THOMAS and CARROLL A. HOCHWALT. Can. 282,205, Aug. 7, 1928. An anti-freeze charge for fire extinguishers comprises two normally sepd. portions, one a compd. contg. a sulfonic acid radical, and the other a soln. of a carbonate, admixed with ethylene glycol to lower the freezing point.

Fire extinguisher. ÉMILE BÉCHARD. Fr. 633,400, Aug. 14, 1926. CCl_4 or other halohydrocarbon is mixed with a mineral, animal or vegetable oil or several such substances are mixed.

Fire extinguisher. AMDYCO CORP. Fr. 632,731, April 13, 1927. Inert materials such as kaolin, talc, starch or flour are added to the ingredients which produce foam. Sulfate of Al contg. not more than 14 mols. of water of crystn. is used as one of the reagents, and the size of the particles is reduced.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

The transparency of glasses for ultra-violet radiations. B. LONG. *Science and Tech.* 12, 13-15(1928).—Glasses of a thickness of 2 mm. can be divided into: (1) Those which absorb all or the greater part of the ultra-violet spectrum. (They contain iron oxide, Ti, Cr, Ce, etc., and are mostly used for eye protection) (2) Those whose permeability is less than 10% for radiations below λ 3100 Å U. (To this class belong the dense flint and barium glasses) (3) Those which transmit rays with λ below 2900 Å U., and of small iron and titanium oxide content. Leaves of 2 mm. thickness were used in windows. Curves are included.

The light absorption of opal glass. G. GEHLHOFF and M. THOMAS. *Z. tech. Physik* 9, 172-5(1928).—For the av. absorption by opal glass bulbs was found 14 to 15% (0.8 mm. glass), the opacity being caused by fluorides. This absorption cannot be explained from the longer path of the light in the glass due to repeated reflections and absorption by the (Fe Mn) gray matter. Expts. on thick clear glass showed that this path was approx. only 3.9 times longer in opal glass. By complete removal of all Fe during the manuf. the absorption could be cut down to 11.6%, an insignificant decrease. Apparently the absorption is due to the opaque particles themselves (cf. Ryde and Yates, C. A. 21, 2365) and not to the impurities in between. B. J. C. v. d. H.

Solubility of glass ingredients. WALTER MEYER. *Chem.-Ztg.* 52, 151(1928).— Et_2O - EtOH after standing in a bottle 2 yrs. contained 0.001% of Se as H_2SeO_4 . Et_2O , MeOH , AmOH and AmOAc showed traces in 3 months and 0.001-0.002% at 0 months. Glass decolorized with Se may, therefore, contaminate neutral and non-aq. solns.

FOSTER DEE SNELL

Cause and removal of certain heterogeneities in glass. L. W. TILTON, A. N. FINN and A. Q. TOOL. Bur. of Standards, *Sci. Paper* 572, 713-36(1928).—Six Ba flint lens blanks from the same melt showed index of refraction deviations as great as 37×10^{-6} from the mean. The index tolerance of $\pm 7 \times 10^{-6}$ within a given blank was exceeded because of optical heterogeneities. Reannealing reduced the max. deviation of index to 12×10^{-6} , each blank showing a marked reduction and in some cases a reversal of sign. Further reduction to 3×10^{-6} without material change in the av. index was produced by prolonged careful reannealing under conditions of nearly constant temp. and symmetrically placed heat conducting material to decrease the temp. gradient of the furnace. Optical density variations which may occur in practically strain-free glass due to heat history differences may be removed by reannealing if the furnace temp. gradients are sufficiently low. In carefully selected glass the max. index deviations due to solely its chem. compn. should be almost negligible. H. F. KIRSON

Neutral glass for vials. MARIO GIORDANI. *Alli congresso naz. chim. pura applicata* 2, 818-29(1926).—As the result of his study of the effect of the heavy metals in glass and devitrification, G. concludes that the appearance of glass heated with water in an autoclave (etching) is not to be confused with devitrification. The ZnO content of the glass is without influence in producing either of these phenomena. The test for alkali, involving the use of HgCl_2 is not very sensitive. Heavy metals need not be prescribed for their presence confers many notable advantages upon the glass, such as greater resistance. Furthermore it has not been demonstrated that they cause devitrification. The max. sterilizing temp. for vials is 120° . L. T. F.

The solidification of amorphous matter. S. ENGLISH. *Roy. Tech. Coll. Met. Club J.* 1927-8, No. 6, 3 6(1928).—Two methods were specially developed for detg. the viscosity of glass with very great accuracy, one for use from a temp. of 1400° down to a temp. 200° above the annealing point of the glass, and the other for the range of 150° to 200° above the annealing point of the glass, the annealing point being defined as the lowest temp. at which internal strains may be removed by free movement of the glass mols. Viscosity curves for Na silicate glasses are approx. hyperbolas. Curves are also given of the mobilities of Na_2O -CaO glasses, showing that the replacement of Na_2O by CaO causes the viscosity at any given temp. to be progressively increased in proportion to the amt of Na_2O substituted. DOWNS SCHAAP

Contribution to the explanation of plasticity. W. MIEHR H. IMMKE AND J. KRATZERT. *Tonind. Ztg* 51, 1381-4(1927).—Plasticity of clays was explained by means of capillary physics. The moldability of clay may be explained by the mol. properties of the clay. H. G. SCHURECHT

Determining the compressive strength. GROOTHOFF. *Tonind.-Ztg* 51, 1418-20 (1927).—Attention is called to the fact that the compressive strength of clay products is influenced by the method of preparing specimens, moisture content, drying temp., speed of drying and construction of the testing machine used. H. G. SCHURECHT

Clay and clinker. HANS HIRSCH. *Tonind.-Ztg* 51, 1315-8(1927).—The effects of various fluxes on clinker were studied. Clinker is a vitrified brick used in Germany for building purposes as well as for paving. The addition of feldspar to brick mixts. was found to be more effective in reducing the absorption of clinker than chalk, magnesite or dolomite. MnO_2 was found to be a more effective flux than Fe_2O_3 . The effects of these fluxes on the strengths of clinker were also studied. H. G. SCHURECHT

The scientific study of the structure of brick. J. E. KIRCHNER. *Tonind.-Ztg* 51, 1475-7(1927).—The effect of the construction of the mouth pieces of auger machines on the production of laminations in brick was studied. Secondary clays are more apt to laminate than primary clays. The laminations may be broken up by putting a perforated plate in the mouthpiece of the auger. H. G. SCHURECHT

Building and paving brick. A. HIRLSCHER. *Tonind.-Ztg* 51, 1566-7, 1601-2 (1927).—The compressive strength of paving brick is 3000-4000 kg. per sq. cm., while that of granite is about 2000 kg. per sq. cm. and that of basalt is about 3000 kg. per sq. cm. H. G. SCHURECHT

Preventing scumming in the manufacture of brick. H. HIRSCH. *Tonind.-Ztg* 51, 1044-6(1928).—The addition of BaCO_3 reduces the SO_2 content of the clay by pptn. During firing the SO_2 increases to a max. at $300-400^\circ$ and becomes reduced to a min. at 1200° . High CaO clays absorb more SO_2 gases during firing than low CaO clays. Firing brick under reducing conditions tends to decompose the scum. F. G. S.

Methods of using barium carbonate for scum prevention in stiff-mud brick. L. P. COLLINS. *Investigations in Ceramics and Road Materials, Dept. of Mines, Can.*, No. 690, 5-7(1928).—Because of the increased popularity and use of rough-textured brick manufd. by the stiff-mud process, the problem of scumming or efflorescence is becoming of increased importance. In several brick plants efflorescence is prevented by the addn. of from 1 to 3 lbs. of BaCO_3 per ton of clay. The factor of primary importance is to obtain a thorough mixing of the Na_2CO_3 and clay. There is no definite evidence as to the superiority of the wet or dry method for addn. of the BaCO_3 . L. B. MILLER

The tunnel kiln in the brick and refractory industry. W. MORITZ. *Tonind.-Ztg* 51, 1634-6(1927).—The tunnel kiln is probably more efficient than the other types of continuous kilns. In comparing the fuel saved by using continuous kilns in the place of periodic kilns it is claimed that the coupled kiln system saves about 30% fuel. The chamber continuous kilns save about 30-70% fuel, while the tunnel kilns save about 57-75% fuel. H. G. SCHURECHT

Control of an old brick ring continuous kiln. P. THOR. *Tonind.-Ztg* 51, 1658 (1927).—The kiln described is 80 m. long, 3 m. wide and 2.4 m. high. It has a capacity

of 520 cu. m. and holds 136,000 bricks. About 50,000 bricks per week are fired in this kiln. H. G. SCHURECHT

Drying with moist air. E. GROSZKINSKY. *Tonind.-Ztg.* 51, 1195-6(1927).—At the entrance of the dryer the air has a temp. of 30° and is about 85% satd. The temp. of the air gradually increases until a temp. of 90° is reached. H. G. SCHURECHT

The firing of sewer pipe. SIECKENIUS. *Tonind.-Ztg.* 51, 1180-2(1927).—By scientific control of the firing of sewer pipe it was found possible to fire a 45-cu. m. kiln in 50 hrs. In 20 hrs. the temp. reached was 120°; in 30 hrs. it was 260°; in 38 hrs. it was cone 016; in 41 hrs. it was cone 06a; in 44 hrs. it was cone 01a; in 46 hrs. it was cone 3a; in 47.3 hrs. it was cone 5a; in 49.2 hrs. it was cone 7; and in 50.5 hrs. it was cone 8. H. G. SCHURECHT

The history of roofing tile. WILHELM LUDOWICI. *Tonind.-Ztg.* 51, 1297-1300 (1927).—The fact that roofing tile were used by the Romans has been revealed in excavations where they were found in a good state of preservation. Improvements have been made in the design of these tiles at different intervals, the most decided improvements having been made in 1881 when the Ludowici tile was patented. H. G. S.

Specifications for roofing tile in Czechoslovakia. O. KALLAUNER. *Tonind.-Ztg.* 51, 975-6(1927).—Roofing tile should be free from apparent defects, impermeable to water, have a uniform dense fracture free from laminations and should be capable of withstanding 25 freezings without failure. H. G. SCHURECHT

French roofing tile. ANON. *Céramique* 30, 517-37(1927). H. G. S.

Burning of roofing tile. A. NAWRATH. *Tonind.-Ztg.* 51, 1293-4(1927).—Firing roofing tile in chamber continuous kilns is described. H. G. SCHURECHT

Bibliography on refractories. ANON. *Tonind.-Ztg.* 52, 264-6(1928). H. G. S.

The present specifications for refractories. H. KNUTH. *Tonind.-Ztg.* 51, 1543-5, 1598-1600(1927).—Specifications for resistance of brick to spalling, coeff. of expansion, resistance to slag attack, and resistance to chemicals are given. H. G. SCHURECHT

Methods for conducting load tests on refractories. W. MIEHR, H. IMMKE AND J. KRATZERT. *Tonind.-Ztg.* 51, 1618-20(1927).—For conducting load tests on fire-brick cylinders about 31.7 cm. high with a diam. of 35.7 cm. are bored out of brick. The furnace used for these tests is usually 50 cm. high with a heating chamber of 25 35 cm. A pressure of 2 kg. per sq. cm. is used and the temp. is increased at a rate of 10° per hr. The data to be collected should include the temp. at which softening commences, and the temp. at which brick has become compressed about 40%. Clay and quartzite brick should withstand a temp. of 1300°, and silica brick should withstand a temp. of 1500°. H. G. SCHURECHT

Yellow discoloration on slip glazes. C. DEGEN. *Tonind.-Ztg.* 51, 1760-1(1927). The yellow discoloration which frequently appears on slip glazes was found to be due to CaFe silicates. The reduction of the lime in the glaze tends to prevent this discoloration. H. G. SCHURECHT

Decomposition of the calcium carbonate in ceramic pastes. MAURIZIO KORACH. *Atti congresso naz. chim. pura applicata* 2, 810-6(1926).—A review and discussion of the formation of craters in ceramic ware owing to the dissocn. of pockets of CaCO₃. L. T. F

Hygienic importance of the permeability of window glass to ultra violet light (EISENBERG) 14. Action of CO₂ on glass at high pressures (BOTVINKIN) 2.

ANDREWS, A. I.: **Ceramic Tests and Calculations.** London: Chapman & Hall, Ltd.; New York: J. Wiley & Sons, Inc. 172 pp. 11s. Reviewed in *Chemistry and Industry* 47, 680(1928).

Apparatus for feeding mold charges of molten glass. GEORGE E. HOWARD (to Hartford-Empire Co.). U. S. 1,678,291, July 24.

Apparatus for feeding mold charges of molten glass. LEONARD D. SOUBIER (to Owens Bottle Co.). U. S. 1,678,232, July 24.

Apparatus for molding blown articles of glass. LEONARD D. SOUBIER (to Owens Bottle Co.). U. S. 1,678,233, July 24.

Leer for annealing glassware. LEONARD D. SOUBIER (to Owens Bottle Co.). U. S. 1,678,234, July 24.

Feeding and shaping molten glass. ENOCH T. FERNGREN (to Owens Bottle Co.). U. S. 1,678,247, July 24. Mech. features are specified relating to the forming of glass articles. An app. is described.

Apparatus for delivering mold charges of glass to molds. C. H. RANKIN and RANKIN AUTOMATIC GLASS FEEDER CO., LTD. Brit. 281,382, Aug. 31, 1926.

Apparatus (of the "press-and-blow" type) for making glassware. T. C. MOORS-HEAD. Brit. 281,383, Aug. 31, 1926.

Apparatus for filling several glass molds at the same time. SOC. ANON. ATELIERS CONSTRUCTIONS MECANIQUEES ESCHER WYSS & CIE. Fr. 633,518, April 28, 1927.

Apparatus for drawing sheet glass. RAUL F. COLE. U. S. 1,678,104, July 24.

Apparatus for making sheet glass by upward drawing. JOHN L. DRAKE (to Libbey-Owens Sheet Glass Co.). U. S. 1,678,060, July 24.

Refractory material. DEUTSCHE GASLÜHLICHT-AUER-GES. Brit. 280,907, Nov. 22, 1926. In making refractory articles of oxides of Zr, Th or rare earths, mixts. of sintered and unsintered materials are heated as rapidly as possible to 1300° or higher.

Porous refractory bricks. I. SETTERBERG. Brit. 281,254, Nov. 26, 1926. Refractory materials as refractory clay, chamotte, kaolin, quartz, flint, magnesite, dolomite, ferrochrome and alundum are mixed with substances capable of evolving gas by reaction with water, *e. g.*, with powdered Al, Zn, Ca or CaC₂, then mixed with water to form a "dough," allowed to rise, dried and burned.

Filtering material. GEORGES DURRSCHMIDT. Fr. 633,018, April 21, 1927. A filtering material is made from abrasives such as corundum, emery, SiC, waste glass and porcelain which are granulated and mixed with powdered agglomerants such as clay, refractory earth borates, molded to the required shape, dried and heated to a temp at which the agglomerants will vitrify and adhere to the surface of the abrasives, leaving cavities all through the material.

Ceramic composition. R. MOHR and H. BECKER (to Patent-Treuhand-Ges für elektrische Glühlampen). Brit. 281,249, Nov. 26, 1926. A ceramic material which is fusible at a "reasonable temp." is formed from siliceous rock such as phonolite mixed with 20% or more of fluorspar or other F-contg. material. Alumina, clay or kaolin may be added; alumina favors devitrification and facilitates the obtainment of a product resembling porcelain. Alkali also may be added and by the prolonging melting operation a more glass-like product is formed.

Ceramic substances containing metals. MAX HAUSER. Fr. 633,047, April 21, 1927. Articles such as cooking utensils and chem. ware are made from an agglomerate mixt. of metals, alloys and non-metals such as oxides, silicates or borates. The mixts. are worked up as for ceramic materials and the ingredients are varied according to the articles required; the articles may be covered with a ceramic layer. Cf. C. A. 22, 1432. Fr. 633,048 describes the use of similar materials for elec. switches, tubes, plates, etc., being made up of conductors and non-conductors.

Silica ware. SOCIÉTÉ QUARTZ ET SILICE. Fr. 632,237, July 15, 1926. Vessels in silica, such as crucibles, are made slightly larger than their final dimensions, placed over a nickel shape, the exterior dimensions of which correspond to the internal dimensions of the crucibles, and heated till they soften and shrink on to the shape.

Spark-plug insulations. F. WOLFF. Brit. 281,548, June 7, 1927. The portion of the insulation nearer to the combustion chamber is formed of heat-resisting material such as porcelain, glass, mica, quartz, steatite or "fiber" and the outer portion is formed from plastic material such as artificial resin subjected to heat and pressure. Various structural details are described.

Rotary furnace for melting enamels, frits, glazes, etc. T. J. VOLKKOMMER. Brit. 280,895, Nov. 22, 1926.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Modern cements. I. White cement, waterproofed and masonry cements. P. H. BATES. *Eng. News-Record* 100, 887-90(1928).—II. High early-strength cements and standard portlands. *Ibid* 932-5.—A general discussion of the characteristics of modern cements. Data given in a tabulation of strength, characteristics of some quick-hardening cements show conclusively that the mortar test in predicting the strength of cement in concrete is valueless.

R. E. THOMPSON
The mechanism of the setting and hardening of cement. TUTOMU MAEDA. *Sci. Papers Inst. Phys. Chem. Research (Tokyo)* 8; Supplement No. 2, 5-7(1928). (In Esperanto).—1. *The reaction.*—(1) At least one constituent of cement must be unstable in a system contg. a liquid phase, and it dissolves in the liquid phase. (2) A soln. super-satd. with respect to the stable compd. then forms. (3) When a new solid phase

seps. from the supersatd. soln., it adsorbs some constituents of the liquid phase. Consequently the growth of the particles of the solid phase is hindered by the adsorbed film and there can be particles of colloidal size. (4) When the supersatd. soln. seps. a new solid phase, the unstable constituents dissolve anew. Therefore particles of the new phase continue to form as long as conditions permit. 2. *Development of strength.*—M. thinks that the particles sepd. from the liquid phase do not have a reciprocal attraction but are united by adsorbed films. When cement is pulled apart the break can occur (1) in the adsorbed film, (2) in the sepd. particles, (3) at the interface between adsorbed film and particle. Beside the relation of at. arrangement in the particle to the direction of traction, the thickness of the adsorbed film is of special importance. If the distance between particles is not mol. and there is a capillary space filled with liquid phase, the strength of the cement will be small. Factors necessary for strength are: (1) Particles sepd. from the soln. must be very small, i. e., the area of interfaces must be very great. (2) The particles must be sepd. by an adsorbed film of mol thickness, i. e., there must be no free liquid phase. (3) The reciprocal attraction between particle and adsorbed film must be large. (4) The strength of the particles must be large. S. Yamane, in the author's lab., has obtained an opalescent suspension of apparently colloidal particles by shaking 1 g. powd. hardened portland cement with 5 cc. glycerol and 30 cc. abs. alc., heating and filtering; no such result was obtained from the original cement. AUSTIN M. PATTERSON

Studies of the occurrences during the setting and hardening of hydraulic cements. K. BIEHL. *Zement* 17, 487-92, 824-8, 934-7 (1928).—Samples of portland, aluminous, and blast furnace slag cements were observed microscopically during the setting processes in the presence of H_2O , dil. H_2SO_4 , HCl , $NaOH$, $Ca(OH)_2$, $CaCl_2$, $MgCl_2$, 9 salts of H_2SO_4 , Na_2CO_3 , $(NH_4)_2C_2O_4$, gelatin, sugar, and sea water (concd. 5 times). The normal processes consist of the formation of (a) needle-like crystals, (b) platey crystals, (c) gels in droplets, and (d) finally the crystn. of these gels. The action of the solns. upon these processes may be accelerating or retarding depending on their concn. If the solns. react with the liberated $Ca(OH)_2$ the crystals of these reactions appear before the normal cement crystn. begins. This occurred with oxalate and sucrose solns. The salt solns. have in general a flocculating effect on the gels. The crystn. is of more significance to the setting process than is the gel formation, while the latter is responsible for the hardening, the slow drying and gradual increase in strength and density of the mass. The effect of gypsum is to retard both the normal crystn. due to its changed soly. product in the presence of the liberated $Ca(OH)_2$ and the gel formation. The strength which gypsum adds to the mass is due to its own crystn. This method of study clarifies the action of both admixts. or naturally encountered substances which disturb the normal set either as retarders or accelerators. H. F. KRIEGER

A plastic mortar compression test for cement. EDWARD M. BRICKETT. *Proc. Am. Soc. Testing Materials* (preprint), 1928, 11 pp.—A compression test of a plastic mortar, of a water-cement ratio approximating 7.5 gal. per sack, shows encouraging possibilities as a specification test showing the concrete-making properties of a cement. RAYMOND WILSON

Methods of obtaining strong gypsum cement. TUTOMU MADA. *Sci. Papers Inst. Phys. Chem. Research (Tokyo)* 8, Supplement No. 3, 8-9 (1928).—By replacing part of the H_2O in a cement mixt. with alc. a stronger cement should result, as the particles sepd. would be smaller. With gypsum cement ($CaSO_4 \cdot 0.5H_2O$), $EtOH$ in fact retards the rate of hardening and increases the strength. $MeOH$ has a similar but greater effect. Portland cement did not show this phenomenon. Gypsum cement heated at 120° 8 hrs. a day for 1 month gives a stronger cement than when unheated. Heating at the highest temp. of the Bunsen burner, however, lowers the strength, even though the cement so treated has the same amt. of H_2O as that heated at 120° . Expts. are being continued. AUSTIN M. PATTERSON

Resistance of portland cement concrete to the action of sulfate waters as influenced by the cement. DALTON G. MILLER. *Proc. Am. Soc. Testing Materials* (preprint), 1928, 13 pp.—Lab. and field tests of 30 portland cements indicate that standard cements from different plants may vary greatly in resistance to sulfate waters. No concordance was found between the resistance to sulfates and the results of standard physical tests or ordinary chem. analyses. RAYMOND WILSON

Increased resistance of cement conglomerates following treatment with fused sulfur. M. G. LEVI AND A. TERNI. *Atti congresso naz. chim. pura applicata* 2, 797-809 (1928).—The tensile strength of normal cement impregnated with S was increased from 2 to 5 times, while the resistance to compression was about doubled. In a cement-sand mixt. of 1:3 the resistance of the sulfured material was 4 times the normal value,

while in 1:5 and 1:7 mixts. it varied between a min. of 5 times and a max. of 10 times the original. With hydraulic cements the effect was much more marked, being 15 times the initial resistance. The resistance to attrition was very marked in sulfured cements and approached in value that of a first quality granite. L. T. F.

Identification of blast furnace slag in cements. H. W. GONELL. *Zement* 17, 437-43 (1928).—Slag cements or slag admixts. can be identified microscopically by the brown to black color produced in the particles when treated with a soln. of $(\text{AcO})_2\text{Pb}$ (2 parts 5% $(\text{AcO})_2\text{Pb}$ soln. plus 1 part 50% AcOH). Portland cement particles color only at their corners while slag particles become uniformly colored because of the more perfect distribution of S in slag. Series of photomicrographs are given to show the intensity of color produced with time. H. F. KRIEGE

Phase equilibria in the system $2\text{CaO} \cdot \text{SiO}_2$ - MgO - $5\text{CaO} \cdot 3\text{Al}_2\text{O}_3$. W. C. HANSEN. *Bur. Standards. J. Am. Chem. Soc.* 50, 2155-60 (1928).—A study of this system was made to det. the condition of MgO in cement. Samples in which the $2\text{CaO} \cdot \text{SiO}_2$ varied from 3 to 48.1%, MgO varied from 2 to 11.2%, and $5\text{CaO} \cdot 3\text{Al}_2\text{O}_3$ varied from 40.7 to 95% were melted in Pt and powdered. Portions of these samples were quenched from temps. between 1290° and 1475° . The portions were examd. microscopically. Tables and graphs report data on 42 quenchings. MgO does not form solid solns. in $2\text{CaO} \cdot \text{SiO}_2$ or in $5\text{CaO} \cdot 3\text{Al}_2\text{O}_3$ nor is it capable of replacing CaO in these comds. F. E. BROWN

Water addition of standard cement mortar mixes. H. LUFTSCHITZ. *Zement* 17, 443-6 (1928).—To obtain uniform consistencies in the mortars for cement testing L. suggests the addn. of H_2O by the formulas: (a) $W/4$, (b) $W/4$ plus $1/4(W/4)$ and (c) $W/4$ plus $1/2(W/4)$, where W is the amt. of H_2O necessary to make plastic the neat cement. Where this is 28% a calls for a 7% H_2O content giving an earth moist mortar while c allows 10.5% H_2O and gives a plastic consistency. H. F. KRIEGE

Experiments on the influence of trass powder and other stone powders on the tensile and compressive strengths, water permeability and resistance to chemical attack of cement mortars. OTTO GRAF. *Zement* 17, 432-7, 492-7, 543-8 (1928).—Moderate addns. of stone powders are beneficial to the density and compressive strength of lean mortars since these are deficient in the finer fractions. In comparison with powd. sand, limestone, slate, mica, kieselsguhr and celite, trass meal admixts. proved most beneficial in compressive, tensile and permeability tests and especially in resisting the attack of 5% MgCl_2 and 5% MgSO_4 solns. An improved consistency was noted for most of the admixts. used. H. F. KRIEGE

Increase in strength of mortar with age. F. KOLKNER. *Zement* 16, 1125-7 (1927).—Plotting the strengths observed against log. of time in days gave a straight-line relationship for compressive, tensile, shearing and flexural tests. In the general formula strength = a plus $b \log D$, the const. a is the first-day strength while b is detd. by the conditions of the test such as mix, amt. of H_2O used, type of stress applied, etc. Thus for a 1:3 mortar the relation between the tensile strength of kg./cm.^2 and the age in days is expressed by strength = 23.0 plus $8.2 \log D$. For 1:5 concrete the flexural strength attained at any age is given by strength = 95.0 plus $14.7 \log D$ under the conditions maintained. H. F. KRIEGE

Comparative strength of concrete pavement cured by three methods. SEARCY B. SLACK. State Highway Dept., Augusta, Ga. *Eng. News-Record* 101, 170 (1928).—The av. compressive strengths at 210 days of concrete pavements cured with earth-and-water, Na silicate and CaCl_2 were 4089, 3906 and 3872 lb. per sq. in., resp. The av. slab lengths after 6 months, detd. by dividing the total length of the section by the no. of cracks plus the no. of joints, were 78, 62.9 and 63.4 ft., resp. The curing methods consisted of (1) covering with 2 in. of earth kept moist for 10 days, removing the covering after 15-20 days; (2) covering with flake CaCl_2 , using $2 1/2$ lb. per sq. yd.; (3) treating the surface with Na silicate, using 1 lb. (42 5° Bé.) per sq. yd. The Na silicate was dild. with water, 3:1, to facilitate covering of the surface. No difference in surface texture could be detected by rough tests. R. E. THOMPSON

Compression strength of oddly shaped concrete specimens. BERNWARD GARRE. *Zement* 17, 273 4 (1928); cf. C. A. 122, 3030.—Test pieces of mortar were made 50 sq. cm. at the base and of varying depths. These were built up on both sides with neat cement until a thickness of 7.07 cm. was attained. The compression values obtained at 28 days can be expressed for 1:3 and 1:9 mortar, resp., by the formulas: compression strength in $\text{kg./sq. cm.} = -10.68 h + 183.8$ and compression strength in $\text{kg./sq. cm.} = -2.56 h + 30.3$, where h is the height in cm. of the mortar piece. H. F. K.

Core tests lead to proportioning by weight. C. E. FORSTER. *Eng. News-Record*

101, 19-21(1928).—Details are given of core tests made on concrete pavements by the State Highway Dept. of Michigan during 1926-7. The results obtained demonstrate the extreme variations in strength of concrete made under volumetric specifications. As a result of the study the 1928 specifications provide for proportioning of aggregates by wt. and accurate measurement of the total water content. R. E. THOMPSON

Impregnation of wood for containers in the chemical industry. FRIEDRICH MOLL. *Korrosion* 3, 25-6(1928).—Impregnation with S is not recommended. J. H. MOORE

Chemically treated fir poles have long life. ANON. *Elec. World* 92, 256(1928).—Four 1/2-inch holes are bored into the butt of a "green" pole just above the ground line. Into the holes is placed a mixture of $HgCl_2$ 1 part, As_2O_3 1 part and $NaCl$ 4 parts. The ingredients are mixed dry by weight and thoroughly blended. The holes are then closed with corks. Moisture from the earth and the sap in the pole gradually turns the mixture into a paste. After a few months the salts are detected in the pole 6 feet above the ground. A \$2 10 fir pole thus treated at a cost of 30 cts. per pole gives the same long life as a cedar pole costing \$5.86. C. G. F.

Cement. NIELS NIELSEN. Fr. 633,493, April 27, 1927. Dust rising from the slurry as it is delivered by a nozzle to a rotary cement kiln is collected and returned to the furnace just in front of the nozzle. A filter to prevent large particles reaching the nozzle is provided in the slurry tank.

Cement. PORTLAND-CEMENTWERK BALINGER, G. m. b. H. Fr. 632,633, April 11, 1927. See Brit. 269,549 (C. A. 22, 1454)

Cement for hydraulic constructions. S. L. A. ODEN, D. R. E. WERNER and STIG. GIERTZHESTROM. Fr. 633,197, Mar 29, 1927. To control the time of hardening of the binding agent it is submitted to the action of gases alone or mixed with H_2O , e. g., H_2SO_4 , HF, HCl, SiF₄, SO_2 , SO_3 and CO_2 which form a crust of matter difficultly sol. in H_2O .

Concrete. BLAW-KNOX Co. Brit. 281,138, Feb. 15, 1927. A system of detg. the voids in sand and stone is described. Sufficient mortar of cement and water is used to fill the voids and provide an excess of mortar.

Coating and impregnating concrete with pitch, etc. R. ROSTOCK. Brit. 281,241, Nov. 24, 1926. Small holes, channels or grooves are formed in the surface of the material to facilitate impregnation.

Waterproofing concrete articles. E. DOGGERT. Brit. 281,022, Aug. 27, 1926. A waterproofing compn. comprises alum and a soln. of shellac which may be dissolved with alc., HOAc, soda, borax or potash, to form a pasty mixt. to which sufficient water is added to carry the paste into the pores of the concrete.

Materials for roads, etc. SOC. ANON. KONINKLIJKE STEARINE KAARSENFABRIEK GOUDA. Fr. 632,923, Apr. 16, 1927. In a material for roads contg. crushed stone and a bituminous emulsion, substances of a sticky nature are added to the emulsion to prevent coagulation in contact with the crushed stone.

Paving blocks. FREDERICK MORTON. Fr. 632,690, April 12, 1927. See Brit. 261,260 (C. A. 22, 3443).

Artificial stone. LÁSZLÓ BOLGÁR. Fr. 632,314, April 6, 1927. Tar residues are heated with acids or acid salts and filling materials such as sand, stone, dust or graphite are added, the whole being stirred till homogeneous and then poured into molds to make drain pipes, tiles, etc.

Composite construction material. ADOLPHUS HERSCOVITCH. Can. 281,898, July

24, 1928. Articles are molded from a mixt. of saw dust, asbestos fibers, MgO, a dry color and a soln. of $MgCl_2$ at 28° Bé.

Gas-fire flue conduits. F. CORNELIUS-WHEELER. Brit. 281,392, Sept. 1, 1926. Flues are constructed of hollow units made of a cementitious compn. including an aggregate of fibrous material mineralized or impregnated by chemical treatment. Various structural features are described.

Millboard suitable for building construction. RICHARD V. MATTISON (to Keasbey & Mattison Co.). U. S. 1,678,345, July 24. A compn. is used comprising hydraulic cement, asbestos fiber and pptd. $CaCO_3$. U. S. 1,678,346 specifies a compn. comprising colloidal hydraulic cement, $Ca(OH)_2$ and $CaCO_3$, subjected to pressure before the cement sets.

Drying wood. BRUCE FORD. U. S. 1,677,963, July 24. Heat is applied to wood, *e. g.*, sheets for *storage-battery separators*, so as to vaporize moisture faster than it can escape from the pores of the wood and disruption of the latter is prevented by mech. restraining the wood, *e. g.*, clamping it between retaining plates.

Preserving wood. LEO P. CURTIN. Fr. 633,302, April 25, 1927. See U. S. 1,659,135 (C. A. 22, 1456).

Preserving wood. GILBERT GUNN. Fr. 632,917, April 16, 1927. See Brit. 273,007 (C. A. 22, 1838).

Apparatus for treating wood. JUVÉNAL MAXIMOFF ET SOC. DITE: BUSS A. G. Fr. 633,458, Aug. 30, 1926. An app. is described in which wood may be treated, either for making cellulose, impregnating it with chemicals, or washing or drying it.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

The recovery of nitrogen from fuel. C. PADOVANI AND I. MUTTI. *Atti congresso naz. chim. pura applicata* 2, 625-37(1926).—The addition of NaCl, CaO or $CaCl_2$ considerably modifies the total ammonia evolved by the distn. of lignite at 950° . A higher yield is always produced by the addn. of 5% of lime, while $CaCl_2$ depresses the yield. The ratio of volatile to fixed NH_3 (with lignite) distd. at 950° was 5.25, while the addition of 6.7% NaCl, 8.2% $CaCl_2$ and 5% CaO gave values, resp., of 0.14, 0.05 and 5.25.

L. T. F.

Some combustion problems in their relation to public health. SAMUEL W. PARR. *Ind. Eng. Chem.* 20, 454-6(1928).—The fundamental factor of life is motion which initially is mol. and has its inception in some form of chem. action. Hence, life and industries today thrive near the reserves of coal and oil, but may in the distant future center in regions now desert, but where the chem. activity of the sun will initiate the required elementary motion. The history of fuels from the discovery of coal in Illinois in 1679 to the present is briefly traced. In 1826 in the U. S. A. 11,000,000 tons of fuel were used, only 2% being smoke producing; a century later 600,000,000 tons were used per annum, 90% of it smoke making. The smoke evil and its causes, cold surfaces, overfilled combustion chambers, especially in domestic furnaces, and some remedies are outlined. The great importance, from technical and health standpoints, of sanitation of the air, reducing the quantities of soot, SO_2 and other fumes in the atmosphere is emphasized. Attention is called to the many advantages gained by complete gasification of fuels before their utilization and to the fact that chemists as well as mechanical engineers are needed to solve the problem. W. W. HODGE

Observations on Lomsakov's grates and combustion chambers. M. HAVELKA. *Paliwa a Topeni* 9, 12-4, 17-26, 33-42(1927).—The Lomsakov (Russian) grates were modified in the Ervénice power plant for use with the Czechoslovakian slate coal. The operating experiences and complete efficiency and working data are given in tables. An English translation of the complete article appears in the same numbers.

FRANK MARESH

Operating results on the Salzburg (Koppers) chamber ovens for 1926 and 1927. A. S. ROSSKOTHEN. *Z. österr. Gas Wasserfach.* 68, 117-24(1928).—A report covering a two-year operating period on a 2-chamber oven, 20 tons daily capacity. Illustrated.

Turner's low-temperature process. G. KROUPA. *Montan. Rundschau* 20, 302-3 (1928).—The results obtained by Turner (C. A. 22, 1840) with his low-temp. coal-carbonization plant, the economics and cost data for the process are given and discussed.

W. W. HODGE

Report of committee D-5 on coal and coke. A. C. FIELDNER, *et al.* *Proc. Am.*

Soc. Testing Materials (preprint) **74**, 1-4 (June, 1928).—A proposed revision of the existing ammonium molybdate standard method of test for *P* in the ash from coal and coke, and proposed new tentative standards for methods of the test for *cu. ft. wt. of coke, cu. ft. wt. of crushed bituminous coal, sieve analysis of coke and a tumbler test for coke* are given with comments. W. W. HODGE

Coals of the Sarre basin. DECIO VITA. *Atti congresso naz. chim. pura applicata* **2**, 638-55 (1926).—Descriptive and statistical discussion of the coal obtained from various mines of the Sarre basin. Analyses are reported for the various types of coal. I. T. F.

Cleaning bituminous coal. J. R. CAMPBELL. *Am. Inst. Mining Met. Eng., Tech. Publ.* No. 117, 31 pp. (1928).—The great value of preliminary studies, feed surveys, screen analyses, sink and float tests of a given coal before installing expensive washing machinery is emphasized. A procedure is outlined for washability tests, the data so obtained being plotted in 4 curves which give a very complete graphic picture of the raw coal and indicate where the impurities lie; also something as to their character, and whether profitable to wash the coal commercially. Ten tables of exptl. data and sets of curves are given for samples of coals from the Elkhorn, Pittsburgh and Kittanning seams and the results are interpreted. The forms in which S occurs in coals and the possibilities of reducing the S content by washing the coals are discussed. Methods of washing coal with water or by air flotation are outlined and flow sheets are given for a simple wet washery (American Rheolaveur Corpn.) and a simple dry-cleaning plant (American Coal Cleaning Corpn.). The relative advantages, indicated applications and references to industrial installations are given for different types of coal-cleaning machinery, launder washers, jigs, concg. tables, tubs and cones, hydraulic classifiers, the S-J. and the Y tables. Methods of drying coal cleaned by wet processes, of sludge and of dust recovery are discussed. Calcs. showing 87.6% qual and 99.76% quant. washing efficiencies, a convenient form of chem. tests data sheet for float and sink expts. at a coal washery, and complete costs data are given for coal washing, together with 4 tables of results of cleaning different coals for metallurgical purposes in 3 going wet washeries and in 1 dry coal cleaning plant. W. W. HODGE

Total carbon in coal. A. R. CARR AND A. M. RENTE. *College of City of Detroit. Ind. Eng. Chem.* **20**, 548-9 (1928).—Descriptions, drawings and manipulations are given for an app. used in detg. the total C in coal from the % CO₂ in, and the vol. of the gas formed when 0.3 to 0.6 g. coal is exploded with approx. 15 atm. of O in a Mahler type bomb. The gas is collected in a rubber balloon submerged in water which fills a large bottle; as the gas fills the balloon the water overflows into a beaker and is weighed. The vol. of gas is calcd. and added to the vol. of bomb and leads. The barometric pressure is added to the reading of the manometer on the app. to obtain the abs. pressure on the gas, and the temp. of the water is noted. The % CO₂ in the gas is detd. over Hg by using a bubbling pipet contg. caustic soln. Tests were made for total C in BzOH and in 5 analyzed samples of different-type coals secured from the Bureau of Mines. Data and calcs. from these expts. are tabulated and show that this method using inexpensive app. gives rapid and accurate results. W. W. H.

Determination of volatile matter in coal. P. S. GROOM AND F. J. WATSON. *Chem. Eng. Mining Rev.* **20**, 323-4 (1928).—In the usual method for detg. volatile combustible matter it is stipulated that the sample shall be heated for 7 min. in a Pt crucible. Expts. with porcelain crucibles show that the results are always lower if the same flame is used as that used with the Pt crucible but if a Meker burner is used the results are very close to those obtained in Pt. W. T. H.

Coal sulfur. Investigations toward the technical utilization of "Arsa coal." M. DOLCH AND E. STRUBE. *Montan. Rundschau* **20**, 213-23 (1928).—The location, properties and especially the high S content of this "Arsa" European brown coal are discussed. The chem. analyses, phys. properties and results of coking tests on 3 samples of the coal obtained from "Arsa," Trieste, are tabulated and show marked differences exist in their appearance, structure, compn., the quality of gas and coke produced and in the distribution of their S contents, i. e., 57.7, 69.0 and 74.2% combustible S; and 42.3, 31.0 and 25.8% ash S, of the total S in the coals which was 7.8, 9.3 and 10.5%, resp. A brief discussion with references is given on methods of detg. S in coals. Results of further expts. are tabulated giving the % total, sulfide, sulfate, disulfide, org. and ash S; also the % which each of these forms of S was of the total S present in a sample of Arsa-coal and in the cokes formed when the coal was distd. at 550°, 600°, 700°, 800°, 900° and 1000°. Total S in the coal was 7.8% of which 7.53% or 96.6% of the total S was org. S; at 700° the coke yield was 82.1%, total S was reduced to 5.24% and org. S to 2.97%, while at 1000° the coke yield was

45.2%, total S 6.7%, but org. S, 0.45% or only 6.7% of the total S in the coke. Results of expts. carried out to det. the effect of different rates of heating at 700° and 800° show that the method of heating is an important factor. Much of the data secured are shown graphically in 4 sets of curves and diagrams. Photographs show the appearance of cokes obtained from Arsa coal when carbonized in: the Al coking app., in a revolving furnace and in a C. T. G. oven. The results of the different expts. are discussed and the conclusion is reached that it is possible by properly coking this Arsa-coal at around 700° so to reduce the total and the org. S and change the chem. compn. and improve the form of the coal that a compression-resistant, stable formed, satisfactory "schwel" coke is produced. W. W. HODGE

The improvement of coal by cooking. FELIX BRAUNEIS. *Montan. Rundschau* 70, 285-92, 321-8(1928).—The theoretical considerations at the basis of the cooking method for coal prepn involving differences in ash and coking properties of the vitrain, clarain, durain and fusain portions of coals; the cell structure of cellulose giving porosity and capillarity to coal; the various forms in which ash, water and S occur in coal; and the colloidal nature of pure coal substance are discussed at some length. Coals from different sources were used in expts. and test runs reported and all showed marked improvement in the dried cooked, over the raw coal, one example being, resp.; water 16.2% changed from 26.7%; ash 7.7%, 13.7%; volatile 34.4%, 31%; fixed C 41.7%, 28.6%; and heating value 5042, 3851 units. Changes made in the S content and in coking qualities were noted in some of the tests. Many tables of exptl. data, computations and graphs are given, also thermal calens and a diagrammatic thermal balance sheet for the process. Sketches are given of a normal coal washery using 6 cu. m., and a coal cooker requiring only 1.6 cu. m. water per ton coal treated. Ground coal is put into boiling water, a reaction takes place such that the outgoing gases from the cooker chamber attain a temp. of around 220°. Approx. 2 hrs are required for the cooking and this is followed by a drying period. Plants have been constructed for the handling of 100, 200 and 400 tons per day. Descriptions, elevation and section drawings are given for a complete coal handling and cookery plant, for an exptl. cooker, and for an automatic industrial-sized cooker of 400-450 tons daily capacity. Costs data and calens showing the profits possible from operating the cookers on Ausrian brown coals are given. W. W. HODGE

The effect of pre-oxidation on the primary distillation products of coal. II. Controlled preliminary oxidation of the coal. JAS. T. HERD, C. HAMILTON FOOTT, HARALD NIELSEN AND JOS REILLY. *J. Soc. Chem. Ind.* 47, 139-42T(1928); cf. *C. A.* 22, 1666.—A description and drawing are given of an improved coal-oxidation app. which insures a large excess of O being always present throughout the mass of coal; the absorption as formed of CO₂; the oxidation (by passing over CuO heated to 270°) of the CO formed to CO₂ and its absorption in a 2nd weighed soda-lime-P₂O₅ tube. A 0.5 mm. constriction in the gas tube regulates the speed of circulation of the gases through the system. The results of a new series of expts. on controlled oxidation of coal, with calens. and graphs, are given. Ten-g. samples of screened 20-30 mesh, undried, Durham coal were continuously heated at 185° in a stream of commercial O (97% pure) for time periods of 1/2 hr. up to 115 hrs., an automatically controlled elec. furnace being used. Calcd. percentages based on the wt. of dry coal used for the 1/2-hr. and 115-hr. expts. were: O used by coal 1.18 and 47.15%; CO₂ evolved 0.13, 17.60%; CO evolved 0.02, 5.51%; H₂O evolved 0.72, 19.63%; O absorbed by coal substance 0.43, 13.72%; increase in wt. of coal 0.32, 4.37%; CO₂/CO ratio 1.72 (1 hr.) and 3.18, resp. Graphs plotted show that in the early stages the CO₂ and CO evolved per unit wt. "total O used" are small, but they gradually assume values proportional to "total O used;" at the same time the CO₂/CO ratio increases until it reaches a const. value of approx. 3. The H₂O evolved was at all times proportional to the "total O used." The curves for "increase in wt. of coal" and for "O absorbed by the coal" are straight lines except for sharp bends at the 3rd and 5th hr. periods, resp. These sharp bends are called "O satn. points." Wt. balances calcd. on the expts. agreed within 0.05%. III. The effect of carbon dioxide, carbon monoxide, hydrogen and nitrogen on coal at temperatures up to 200°. W. J. BARRETT, C. HAMILTON FOOTT AND J. REILLY. *Ibid* 142-3T.—In the app. previously described (*C. A.* 22, 1666), sep. 10-g. portions of Durham coal were continuously heated at 200° in circulated currents of CO₂, CO, H and N for 7 days. Methods of prep. the gases are given; each was dried over CaCl₂ and P₂O₅ before introduction to the app. Analyses of the gases in the closed glass system before and after heating showed that no interaction had taken place. Approx. similar results were obtained with each of the 4 gases, the one with N being given as typical. The water evolved at 200° was in each case slightly

in excess of the moisture as detd. at 105°, but was a little less than the loss in wt. of the coal substance. For the N expt. these values were: loss in wt. of coal 0.798%; wt. H₂O evolved 0.772%. The "wt. balance" agreed within 0.10%. IV. The distillation at 600° of the oxidized coal samples. JAS. T. DONNELLY, C. HAMILTON FOOTT, HARALD NIELSEN AND JOSEPH REILLY. *Ibid* 189-92T.—The samples of coal oxidized in Part II of this investigation were distd. in a glass retort (16 × 2.8 cm.) while N was continuously recirculated through the coal and the app. The retorts in a horizontal position in an elec. furnace were heated up to 600° in 1 hr. 20 min. and then held at this temp. for 10 min. The products evolved were collected: (1) anhyd. heavy tar in a vertical Y glass condenser kept at 101° by a boiling brine bath; (2) light tar and water in a vertical glass condenser kept at -18° by a freezing mixt. bath; (3) volatile hydrocarbons in U-tubes filled with granular activated C; (4) traces of H₂O and tar oils in P₂O₅ tubes; and (5) the gas in a graduated cylinder over Hg. Water collected in (2) was quant. detd. by Masson's CaC₂ method. A description, 3 drawings and details of manipulation of the app. are given. Distn yields obtained from the untreated coal and from 8 portions of the coal which had been pre-oxidized for different periods of time are tabulated and some graphs plotted. Coke silhouettes show how the raw coal and the cokes appeared in their glass retorts. Distn yields calcd. on % wts. on dry untreated coal indicated a gradual falling off in wt. % of heavy and light tar fractions and of volatile hydrocarbons, but higher % yields of water and gas the longer the coal had been subjected to pre-oxidation. Swelling and coking properties decreased with increase in time of oxidation; the raw coal gave a strong, highly swelled coke; the coal pre-oxidized for 1 hr. was only moderately coking and swelling, while the coal which had been pre-oxidized for 115 hrs. was non-coking. Tars from the untreated coal were unstable and rapidly darkened in air, but tars from the longer pre-oxidized coals were quite stable. A more detailed investigation of the effects of preoxidation on the compn. and properties of distn. products of coal is now in progress.

W. W. HODGE

Oxidized coking coal as a raw material and fuel. R. KATTWINKEL. *Gluckauf* 63, 160-5; *Chem. Zentr.* 1927, I, 3164-5.—Three Westphalian coking coals, 2 fat coals and a gas coal were maintained for 90 days at 80° in beds 80 mm. deep in a steam drying oven and in this way oxidized. This treatment destroyed their caking power, caused a gain in wt. of 1.75, 2.92 and 3.50%, resp., increased the O content and changed but slightly the grain. The yield of coke changed very little; the yield of tar and of C₆H₆ diminished greatly; while the yields of gas liquor and of NH₃ were greater after oxidation. With respect to the yields of gas, the different types of coal differed to the extent that after oxidation the yield from the gas coke diminished much more than did the yield from the fat coals. The decreases in the calorific values were 5.37, 5.61 and 10.03%, resp., for the 3 types of coal. The ash, m. p. and the point of flow were not changed by oxidation of the fat coals, while the ash of gas coal began to fuse 25° lower after the treatment, which is attributed to an increase of about 0.5% in the Fe content of the ash. The mineral components of gas coal are therefore affected by the oxidation.

C. C. DAVIS

The influence of oxygen upon the ignition of fluid fuels. H. PAHL. *Z. Ver. deut. Ing.* 72, 857-60(1928).—Known mixts. of O and air were purified and led through a heated Cu tube into an "ignition block" contg. an 11-cc. combustion chamber provided with a small orifice for introducing the fuel studied. The block was heated electrically and its temp. detd. by an Fe-constantan thermocouple. Curves for temps. of ignition were plotted against O content of the atm. used. Fuels studied were C₆H₆, C₂H₅OH, benzene (d. 0.725) and "American gas oil" (d. 0.859). For C₆H₆ a gradual fall of ignition temp. from 840° for 10% O to about 700° for 100% O was obtained; for allyl alc. similarly it fell in a rather regular fashion from about 450° for 20% O to 393° for 100% O. With benzene there was irregular fall from 500° for 20% O to about 300° for 33% O, and after that the ignition temp. remained const. to 100% O; for the "American gas oil" there was an irregular fall from about 500° for 20% O to 265° for 22% O, and after that it, too, remained const. These facts are explained upon the basis of cracking complex hydrocarbons into simpler ones. The time from the fall of a drop of fuel into the combustion chamber until the ignition took place was taken as the "delay" or "lag" in explosion; for allyl alc., benzene and "American gas oil" it increased with the decrease of the O content as well as with the temp. concerned. The intensity of the explosions was measured roughly by comparing the heights of the flames produced; they decreased with decreasing O content. The expts. have shown that in the case of hydrocarbons of high mol. wts. the ignition temps. and time of lag are quite different with low and high O contents; with low O content mixts.

they behave like simple compds., like C_4H_6 and C_2H_5OH , indicating that by pyrogenic reactions they are first broken down into simpler hydrocarbons and then the explosion or ignition takes place. The surroundings have a great deal to do with the temp. of ignition and the nature of the explosion, as illustrated by the conditions of the walls of the combustion chamber, the amt. of heat stored in them, etc. W. C. EBAUGH

Determination of the heating value of coal by the Geipert method. K. BUNTE AND W. ZWEIF. *Gas u. Wasserfach* 71, 629-31(1928).—Tests of the quantity and the calorific value of gas from various gas coals as made by the Geipert method (C. A. 21, 166) agree fairly well with the semi-plant scale test results on the same coals. Three 10-g. portions of the coal are gasified in a special quartz furnace. Special means are given of detg. the calorific value of the small amt. of gas in an ordinary Junkers calorimeter, slightly modified, and a measuring flask. Precautions are given for securing comparable results. R. W. RYAN

Industrial low-temperature distillation of brown coal. HUGO NOVAK. *Paliva a Topeni* 9, 26-31, 42-6, 61-4(1927).—A discussion of low-temp. distn. practised in Germany, France and America is given in complete form with suggestions for new retorts and adaptations for com. use. Suggestions follow for adapting the present retorts to Czechoslovakian brown coal which does not seem to be suited for low temp. distn. FRANK MARESH

The investigation of brown coal from new points of view, with particular reference to the volatile coal constituents. M. DOLCH AND K. GIESELER. *Universitätsinst. f. tech. Chem., Halle a. d. S. Braunkohle* 27, 581-7, 608-13(1928).—The following method is proposed in place of the combination of low-temp. carbonization tests with the crucible analysis for the detn. of gas and tar. Al is unsuitable for complete carbonization because of the high temps. required. The usual Fischer retort was therefore replaced by a steel one of similar design, sealed with Pb and heated in a specially made electric furnace so designed that the temp. could be accurately controlled for the various stages. The coal was first dehydrated in a stream of CO_2 or N_2 at 110° , then carbonized to semicoke at 530° and finally degassed at 900° . Free and combined H_2O , primary tar, low-temp. and high-temp. gas and final coke were thus detd. in a single run. The results were closely reproducible. They were compared with crucible analyses and with results from the Fischer Al retort and Strache small tube. The final coke checked the crucible-fixed C closely. The H_2O values were checked by the xylene method. The volatile was somewhat higher than by the crucible analyses, in which the final temp. has been found to be about 750° , and considerably higher than with the Al retort. Detailed results, including gas analyses, for two brown coals and a bituminous coal are given and discussed with reference to information required in industrial practice. F. S. GRANGER

Recent developments in the production of motor fuels from coal. A. C. FIELDNER. *Bur. Mines, Circ. No. 6075*, 18 pp.(1928); cf. C. A. 21, 1175. E. H.

Fuels for motor vehicles with regard to the situation in Czechoslovakia. JOSEF ZD'ARSKÝ. *Chem. obzor* 3, 15-7, 42-4, 79-84(1928).—The substitutes and admixts. of gasoline, the use of which was recommended by J. Formánek more than ten years ago are: benzene, toluene, alc., kerosene, ether, tetralin and gas oil. The first in admixt. with gasoline till to 50% (for heavy trucks) is especially suitable to give a motor fuel devoid of knocking. Another fuel, dynalkol, widely used in Czechoslovakia, originally consisted of 60% benzene and 40% of 96% alc.; at present it consists of 50% of 96% alc., 30% gasoline and 20% motor benzene. The wt. of the carburettor float must be increased 5% as the mixt. has a higher sp. gr. (d_{15} 0.806) and the opening diam. of the main carburettor nozzle must be enlarged by 8% and the air preheated. Dynalkol with abs. alc. was tried also as an airplane motor fuel with success. Other motor fuel possibilities are briefly discussed. JAR. KUCERA

Determination of gasoline, benzene, alcohol, ether and tetralin in liquid fuels for motor vehicles. II. JAR. FORMÁNEK. *Chem. obzor* 3, 33-4(1928).—Tetralin (d_{15} 0.9800, refraction of colorless 1.5440, yellow 1.5470) can be detected as a higher fraction of motor benzene or heavy gasoline b. above 200° , by purified algol red B (also BTK), which colors tetralin intensively red or by lacquer red Ciba B, by detn. of sp. gr. and refraction, or chemically by 1% KI soln. + starch + 2 drops dil. HCl (1:4). The soln. becomes instantly dark blue, after a short time violet and after restirring and 30 min. green. Kerosene gives this reaction only slightly; gasoline, benzene and alc. show no reaction. JAR. KUCERA

The sulfur content of lignites. C. PADOVANI AND S. SCHIAVI. *Atti congresso naz. chim. pura applicata* 2, 609-24(1926).—Samples were prepd. in the usual way and the moisture contents detd. Total S was detd. by several methods of which Parr's

method furnished most consistent results. In addition the combustible S, volatile S and fixed S were detd. Distinction between the various forms of S present was based upon the method of Powell and Parr. Distn. in an inert gas was investigated with a view of further sepg. the volatile S. The S that passed into the distillate at various temps. was measured. A typical lignite (Bacu Abis) showed the following sulfur picture: free S 0.31%, S as pyritic S 3.41% and org. S 4.70%. L. T. FAIRHALL

Advances in furnace construction. H. WELLMANN. *Wärme und Kälte Tech.* 28, 79-82(1926).—The chain grate described has an area of 22 sq. m., and has a special compartment in which coal falling through in the first zone is collected. E. W. T.

Preheated air for boiler furnaces. P. H. N. ULANDER. *J. Inst. Fuel* 1, 187-212 (1928).—A discussion of the use of air preheaters for boiler furnaces, particularly in conjunction with economizers. LESLIE B. BRAGG

Determination of water in combustibles with the aid of magnesium methyl iodide. A. TAUBMANN. *Z. anal. Chem.* 74, 161-7(1928).—Zerewitinov showed in 1911 that water could be detd. in substances insol. in pyridine by extg. with it and adding $Mg-CH_3I$ to the resulting soln. of water in pyridine. Water reacts with the org. Mg compd., liberating 2 mols. of CH_4 which can be measured. This method applied to the detn. of H_2O in coal, coke, peat, lubricating oil and naphtha is now found to give results surprisingly close to those obtained by vacuum drying and much more reliable than those obtained by drying in a thermostat. Moreover, since 1 mg. of water liberates about 22 ml. of CH_4 , a small wt. of sample can be used. W. T. H.

Measurement of steam flow in works practice. H. C. ARMSTRONG AND T. NORDENSON. *J. Inst. Fuel* 1, 161-86(1928).—The value of steam flow measurement as a means of obtaining valuable information as to the production or utilization of steam by the various pieces of equipment is discussed. Flow meters and the calcn. of the flow are also considered. LESLIE B. BRAGG

Operating experiences with 1300-pound steam pressure. JOHN ANDERSON. *J. Inst. Fuel* 1, 131-60(1928).—Major troubles have been experienced in the operation of the high-pressure installation at the Lakeside Station in Milwaukee, largely due to scale and corrosion, but it is felt that widespread adoption of 1300 lb. pressure will occur in the near future. The experiences are discussed in detail. L. B. B.

Operating experience with high pressure and high temperature steam. GEO. A. ORROK. *Combustion* 18, 308-10(1928).—A review of operating experience and high pressure development in the last five years. LESLIE B. BRAGG

The generation of steam in the gas plant. F. T. LEILICH. *Combustion* 18, 181-2 (1928).—A discussion. LESLIE B. BRAGG

The producer gas process. J. G. DE VOOGD. *Het Gas* 48, 214-24(1928).—The work of Haslam and collaborators is reviewed and compared with practical experience at the Rotterdam gas plant. The calorific efficiency of a producer (total cal. in gas divided by those in fuel) is the most important factor for operation; it can easily be calcd. from a gas analysis (neglecting C loss in ashes) by $70.5 (CO + H_2) / (CO + CO_2) \%$ for the upper value (liquid H_2O) or $(70.5 CO + 60 H_2) / (CO + CO_2) \%$ for the lower value. From some numerical data on a Pintsch producer it is shown that a slightly lower heating value of the gas is sometimes accompanied by higher efficiency; a gas with 6.5% CO_2 , 1071 cal. per cu. m. was made with 80.9% efficiency (lower value), one of 4.3% CO_2 , 1082 cal. per cu. m., 79.8% efficiency. Low CO_2 content is a quite unreasonable criterion for the gas quality, a 3.2% CO_2 gas is shown of 60 cal. lower heating value and 5% lower efficiency than a 6.5% CO_2 gas. Increased steaming of central or built-in producers increases the vol. of the stack gases somewhat, but at the same time it promotes better heat transfer by radiation due to the H_2O vapors (Schack). The desirability of gas of const. quality in particular for built-in producers is stressed; for the latter high const. heating value is ideal. Higher fuel bed will not increase the height of oxidation or reduction zone; higher throughput may, up to a limit (higher temps.), raise the efficiency notwithstanding a shorter time of contact (up to 300 kg. coke per hr. and sq. m.); Haslam's results on a small exptl. producer may in this respect be misleading because of his relatively much larger radiation influence. The fuel bed should be 2-4 m. high. The most efficient steam: fuel ratio appears to lie around 0.7, i. e., considerably more than formerly found (around 0.4 by Bone, Clements, etc.); it apparently increases with increasing throughput. From concurrent CO_2 content and heating value charts on a Pintsch producer it was found that high CO_2 (high steam) is usually accompanied by high calorific value (between 1050 and 1250 cal. per cu. m.) (CO_2 from 2 to 7%) and also high efficiency. Figures tabulated from tests over 3-7-hr. periods of const. CO_2 content show increases of the efficiency from 82% (4% CO_2) to 85% (6% CO_2) and decreasing N_2 . The limit, to

be expected from cooling down of the reduction zone, is apparently high. The kg. steam per kg. carbon gasified (coke 86.6% C, 10.6% ash) ran in some expts. from 0.62 to 0.82; steam decompn. 88 to 65%; cals. per cu. m. (lower value) 1050 to 1174 for CO_2 , 5.8 to 6.4%; efficiency 81.3 to 86.3%, kg. coke per sq. m. hr. 137 to 110. A sharp relation between throughput and efficiency could not be established. B. J. C. v. D. H.

Determination of the calorific value of gas with a measuring flask and a Junkers calorimeter. ANON. Gas Institut. *Gas u. Wasserfach* 71, 660-1(1928); cf. C. A. 21, 813.—The gas is collected in a 12-l. calibrated flask, preferably provided with a water jacket. Means are described for insuring a const. flow of gas to the calorimeter. A 1-mm. jet is provided in the calorimeter burner. Comparative analyses for this method and the usual Junkers method are given for city gas and coal gas and these values agree well. R. W. RYAN

Determination of carbon monoxide in flue gases. K. HOFER. *Glückauf* 63, 660-1; *Chem. Zentr.* 1927, II, 200-1.—To det. CO on the spot in flue gases, where the usual method with CuCl_2 in an Orsat app. is not sufficiently precise, it is recommended that 2 Wilhelm pipets with 90 and 110 cc., resp., of ammoniacal AgNO_3 soln. be used and the detn. carried out as a purely colorimetric method. C. C. DAVIS

Measurement of the quantity of flue gas and its calculation from the amount of combustible material and the flue gas analysis. W. POHL. *Gesundh. Ing.* 51, 433-9, 452-7, 467-73(1928).—A mathematical discussion of the subject matter. Tables of tests in which different kinds of combustible material were used are given. P. finds that in order to obtain accurate analysis of flue gas consideration must be taken of the factor g/g_0 , where g is the quantity of flue gas per unit time and g_0 the av. quantity of flue gas per unit time. With this method it was found that the max. error of the uncorrected flue gas analysis is 11%. Under these conditions the efficiency of the furnace is calcd. to be 3% higher than the true value. WAYNE L. DENMAN

Gases absorbed in coal. R. VONDRÁČEK AND B. HLAVICA. *Paliva a Topeni* 9, 2-12(1927).—Large lumps of fresh coal from Ostrava, Rosice, Nřany, and Handlová, Czechoslovakia, were finely pulverized, filled immediately into glass bombs sealed with wax and evacuated. Evacuation commenced at 20 mm. and was reduced to 1 mm. It was continued until the daily increment of the gas was 1 cc. The bomb was submerged in an oil bath at 100° and the 24-hr. fractions were analyzed in a Hempel app. The CO was detd. by absorption in acid cuprous chloride or by combustion with H over Cu_2O at 250°, or absorption with anhyd. iodine pentoxide; CH_4 and satd. hydrocarbons by combustion over Cu_2O ; unsatd. hydrocarbons by absorption in Br water. Gases found regularly were: CH_4 0.0-59%, CO_2 0.8-11.8% and N_2 34.5-93.8% of gas evacuated. H was never found—not even at 100°; CO was less than 0.1% when found; unsaturated hydrocarbons were less than 0.02% (lignite Handlova showed 0.5%). Ethane and higher hydrocarbons were not found in fresh specimens. Coking coals showed a $\text{CH}_4:\text{CO}_2$ ratio which remained around 3; while gas coals had a $\text{CH}_4:\text{CO}_2$ ratio of 15. During evacuation, CH_4 escapes more rapidly than CO_2 . The gas evolved varied from 24 to 296 cc. per 100 g. of coal. Tables of results and a complete résumé follows in French. FRANK MARESH

Concerning certain special operating methods in American oil-water-gas plants. J. GWOSDZ. *Erdöl u. Teer* 4, 354-6(1928).—A discussion mainly of the blow-run and back-run processes with statistical data. F. S. GRANGER

Oxide purification. GUSTAV OFFE. *Am. Gas J.* 129, 37-40(1928).—See C. A. 22, 1841. E. H.

Low-temperature tar. G. E. FOXWELL. *Gas World* 89, Coking Sect. 13-5(1928).—A discussion. A satisfactory return on the tar is essential to the com. realization of low-temp. carbonization. Present difficulties, which should disappear in time, are the small quantity of such tar available and the lack of uniformity of the tars from the 250 proposed processes. The present method of disposal, by tar distillers, is by concealment in relatively large quantities of high-temp. creosote. Various possibilities of utilization of the tar as a whole or of its constituents individually, and current investigations along this line, of which wood preservation has already shown promising practical results, are reviewed with particular reference to recent articles by G. T. Morgan and H. D. Savage. F. S. GRANGER

Dust and ash determination in tar. R. ARBEITER. *Chem. Ztg.* 52, 529(1928).—Tar (4-5 g.) is placed in a pleated filter sustained in a bottomless crucible on a small glass tripod. The whole is placed in a beaker contg. CCl_4 , but not enough to reach the filter. The filter is covered with a round-bottom flask through which a current of cold water is maintained. A hot plate is used to boil CCl_4 , which condenses on the bottom of the flask. To prevent the condensate from hitting the filter and damaging it,

a glass arm is used with a flattened tip; it catches the falling drops and directs them onto the filter. After 30-40 min. the filter is dried and weighed, giving the amt. of ash and dust directly.

A. L. HENNE

Coke ovens. The aspiration of gases and its automatic regulation. C. ARNU. *Tech. moderne* 20, 452-8(1928).—The various app. used for the automatic control of gas flow in coke ovens are described.

P. THOMASSET

The dry coke-cooling system of Collin. ERNST ARNOLD. *Stahl u. Eisen* 48, 903-7(1928).—The Collin dry coke-cooling system consists of cooling chambers, one for each 3 coke-oven chambers, in which the coke is cooled from 750° to 220° in about 8 hrs. by a circulating current of gas. The hot gases leaving the chambers are collected and led into the waste heater steam generator where 400 kg. steam is produced after each ton of coke cooled. This cooling system is most advantageous in plants where the steam consumption is high, such as the Heinrichshütte at Hattingen, the cooling system of which is described in detail. Plans and cost of operation are given. The dry-cooled coke is as good as, if not better than, the wet-cooled coke.

J. A. S.

Does dry or wet quenching influence the reactivity of coke? G. A. BRENDER & BRANDIS and P. VAN'T SPIJKER. *Hel Gas* 48, 208-10(1928); cf. *C. A.* 21, 2376.—Coke samples were gathered (a) from the coke crusher (wet quenched), (b) hot from the retort and cooled in a closed steel vessel, both samples being from the same charge (vertical retort). The combustion rate at const. temp. in air was detd. (vertical elec. furnace with quartz tube, filled with fireclay granules and 3-cm. coke, 2 to 4 mm. size at 575°). From the O₂ content (CO and CO₂ also detd.) of the gases leaving it follows that the samples (a) were slightly more reactive, contrary to current opinion, than (b), e. g., for 3 sec. contact of air and coke (a) gave about 6, (b) 12% O₂. At higher temps. this difference becomes negligible. The ignition temp. in air according to Bunte, detd. in the same tube, air velocity 15 l. per hr. gave for wet quenched coke 498°, dry quenched 519°.

B. J. C. VAN DER HOEVEN

The formation and structure of cenospheres. F. S. SINNATT. *J. Soc. Chem. Ind.* 47, 151-5T(1928).—The importance of different kinds of coke in modern industry, the many layers and varying quantities of vitrain, clarain, durain and fusain in coal seams and effect of these variations on the coking properties of coals are outlined. Previous investigations on cenospheres are reviewed and discussed (cf. *C. A.* 21, 3262, 3729; 22, 310). A description and drawing are given of the vertically placed silica tube (28½" × 1½") and app. used to produce cenospheres by heating powd. (60/90 or 40-50 mesh I. M. M.) coal or pitch at different temps. from 420° to 950°. The properties and appearance of cenospheres, lattices, windows and tertiary structure (window spots) are described and illustrated with 8 photomicrographs of cenospheres obtained from coal or pitch, sugar, dust from a cement works and after the original cenospheres had their windows and lattices burned out or modified by higher temp. or CO₂. With a coal of 23.7% volatile matter the temp. of formation of globules larger than the original coal particles was 530° and there was a 6.2% loss in volatile matter from the carbonized globule. Differences in appearance, diameters and coking properties of cenospheres formed at 500°, 550° and 600° from durain, vitrain and clarain are tabulated. The av. diam. of cenospheres from clarain at 800° was 0.55 mm. The smallest cenosphere had approx. the same size as the original coal particle while the largest cenosphere was about 40 times the vol. of the coal particle. The wt. of a cenosphere has been found to be approx. 2.0 × 10⁻⁶ g. The sp. gr. of cenospheres is taken to be about 0.2 to 0.5 which may account for the collection of quantities of them in the dust from locomotives, a channel steamer and from a cement works (4000 deposited per sq. ft. in 8 hrs. at ¾ mile from the works). Possible correlations between the structure and method of formation of cenospheres and of lump coke are mentioned. A general discussion follows the article.

Motor fuels. I. G. FARBENIND. A.-G. Brit. 281,247, Nov. 26, 1926. Fuels with "anti-knock" properties are made by destructive hydrogenation of highly bituminous coals or like material by extg. the bitumen before or during the treatment, *e. g.*, by use of a solvent such as benzene before the hydrogenation.

Motor fuels. RUTGERSWERKE-AKTIENGESellschaft and LEOPOLD KAHL. Fr. 632,193, Apr. 5, 1927. A motor fuel comprises a eutectic liquid mixt. of hydrocarbons individually solid at ordinary temp. either alone or mixed with benzene, etc.

Liquid fuel produced by destructive hydrogenation. L. T. BATES. Brit. 281,240, Nov. 23, 1926. Hydrocarbon oils and coal are subjected to hydrogenation together in the presence of a catalyst (in an app. which is described) to obtain a fuel suitable for use in "semi-Diesel" or "hot-bulb" engines.

Fuel briquet. ROBERT M. HALE (to Minerals Separation North American Corp.). U. S. 1,678,387, July 24. Coal finer than 20 mesh is bonded with a binder which contains a considerable proportion of oil, a considerable proportion also of sulfite cellulose residues and substantially no added inorg. material.

Fuel briquets. GEORGE A. CHAPMAN and ELTOFT W. WILKINSON (to Minerals Separation North American Corp.). U. S. 1,678,379, July 24. Briquets which are adapted when burned in a deep mass in a grate to leave an ash contg. less than 10% of unconsumed C and which burn at least nearly smokelessly and without substantial softening are formed by molding and baking a mixt. of uncoked anthracite coal substantially passing 10 mesh with a binder consisting mainly of oil residue which is less than 10% of the coal.

Fuel briquets. ALBERT L. STILLMAN (to General Fuel Briquette Corp.). U. S. 1,677,994, July 24. A mixt. of coal 90, molasses lcs 5-7 and sulfite liquor 5-3% is ground, crushed and kneaded, molded and carbonized.

Fuel packages. E. W. BOWEN. Brit. 281,411, Sept. 9, 1926. Molded block or "ovoids" of artificial smokeless fuel are packaged in a container which may be formed of paper, together with readily ignitable materials such as wood, shavings, resin, $C_{10}H_8$ and tar.

Briquetting non-caking fuels. P. FUCHS (to Friedlaender & Co.). Brit. 281,326, Nov. 27, 1926. Non-caking fuels are briquetted with a binder consisting of a mixt. of org and inorg. substances, *e. g.*, waste sulfite liquor constituents and lime or cement. $C_{10}H_8$ and lime slaked with a satd. $MgSO_4$ soln. also may be used; and MgO may be mixed with the lime before slaking in different proportions according to the hardness desired.

Synthetic fuel. SOC. INTERN. PROCÉDÉS PRUDHOMME (S. I. P. P.). Fr. 633,112, Aug. 3, 1926. See Brit. 275,585 (C. A. 22, 2259).

Distilling powdered coal. A. GAERTNER. Brit. 281,110, Dec. 29, 1926. Finely divided coal is injected into a coking chamber solely by combustion gases. H or a gaseous mixt. such as water gas, contg. H, and a catalyst such as a finely divided metal may be used or injected into the distg. chamber. An app. is described.

Carburation of methanol. ÉMILE P. DUMANOIS. Fr. 633,443, Aug. 27, 1926. To obtain a fuel having a calorific value higher than MeOH, other alcs., aromatic hydrocarbons or products from the carbonization of oil are added. An example gives a mixt. of 70% by vol. of MeOH, 15% of EtOH and 15% of benzene.

Producing or modifying oils. RICHARD FEIGE. Fr. 632,293, April 6, 1927. Combustible solids, liquids or gases or tar or tar products are submitted to a high-tension elec. current, under pressure or not, to increase the low-boiling constituents. Catalysts may be added, or the electrodes may be made of a substance having a catalytic action such as tin.

Annular rotary-hearth tunnel furnace suitable for drying or distilling coal or lignite in thin layers. TROCKNUNGS-, VERSCHWELUNGS-, UND VERGASUNGS- GES and F. BARTLING. Brit. 281,169, May 13, 1927.

Furnace. FERNAND A. MARAS. Fr. 632,654, April 12, 1927. Construction details of hearth.

Furnaces. WALLSEND SLIPWAY & ENGINEERING COMPANY, LTD. Fr. 632,673, April 12, 1927. The burner of a furnace is adapted to use either powdered coal or a liquid fuel.

Furnaces. LUCIEN BRIGANDET. Fr. 633,022, April 21, 1927. To allow of charging by gravity the hearth of a furnace is sloping downwards.

Furnaces. GUSTAVE M. RIBAUD. Fr. 632,343, April 7, 1927. Furnaces, especially *elec. furnaces*, have a liquid heating medium of greater density than the material to be heated, and this liquid is rotated at a suitable speed to form a cavity in the center of which the material tends to remain.

Dust furnaces. SIEMENS-SCHUCKERT WERKE. Fr. 633,525, April 28, 1927. The combustion air is led into the furnace with a whirling motion whereas the dust fuel is led in approx. perpendicularly to the plane of the air whirl.

Furnace for liquid fuel. STEAM PRODUCTION CORP. Fr. 633,494, April 27, 1927.

Apparatus for charging furnaces with powdered fuel. FAY HARRY ROSENCRANTS. Fr. 633,031, April 21, 1927

Vertical retort furnaces. LOW TEMPERATURE CARBONISATION, LTD., and C. H. PARKER. Brit. 281,348, June 7, 1926.

Funnel for automatically charging gas generators or other furnaces. SOC. GRILLES ET GAZOGÈNES SAUVAGEOT. Fr. 633,580. April 29, 1927.

Down-draft gas producer. K. A. WIDEGREN and E. H. WIDEGREN. Brit. 280,912, Nov. 22, 1926. Structural features.

Gas. I. G. FARBENIND. A.-G. Fr. 632,466, April 8, 1927. In producing combustible gas from granular combustible solids, the solids are maintained by gasifying agents in progressive movement during the gasification either by carrying along the combustibles by gasifying agents having a sufficient speed, or by carrying along the combustibles first with air to transform the fine particles into producer gas and then with steam to transform the remainder into water-gas. Cf. C. A. 22, 2830.

Gas. RUDOLF LEDERER. Fr. 633,470, April 27, 1927. See Brit. 270,318 (C. A. 22, 1463).

Gas. OTTO MISCH. Fr. 632,826, April 15, 1927. An app. for the production of a gas having a calorific value of 3500 to 4500 calories per cu. m. from bituminous fuel is described.

Gas purifiers. SOC. INTERN. PROCÉDÉS PRUDHOMME. Fr. 632,360, July 21, 1926. See Brit. 267,138 (C. A. 22, 1200).

Gas purification. HUMPHREYS AND GLASGOW, LTD. Fr. 632,777, April 14, 1927. The purifying soln. contg. alkali sulfhydrate is revived by a paddle turning at high speed in the soln. under which air is bubbled.

Gas purification. FREDERICK W. SPERR, JR. (to Koppers Co.). U. S. 1,677,304, July 17. A liquid such as the waste NaOH soln. from the artificial silk industry which has been used for purifying gas from acidic impurities is regenerated by the action of air in the presence of hemicellulose which serves to increase efficiency of flotation and removal of S which is liberated.

Purifying coal gas and similar gases. C. COOPER, F. B. HOLMES and W. C. HOLMES & Co., LTD. Brit. 281,474, Nov. 30, 1926. After cooling the gas to obtain an aq. condensate contg. NH_3 the gas is subjected to the conjoint action of the condensate and of CaSO_4 and CO_2 may be introduced. Numerous details and modifications are given.

Desulfurization of gas. L'AIR LIQUIDE (SOC. ANON. POUR L'ÉTUDE L'EXPLOITATION PROCÉDÉS GEORGES CLAUDE). Fr. 632,559, July 30, 1926. The process of Fr. 585,979 for the desulfurization of coke-oven and other gases is improved by replacing Na glycerolate by other org. or inorg. glycerolates, by which means not only COS but CS_2 and the mercaptans are removed.

Gas rich in carbon monoxide. H. NIELSEN and B. LAING. Brit. 281,105, Aug. 25, 1926. In producing gas rich in CO by passing CO_2 through a mass of coke at a temp. of 750–850°, the semi-coke used as described in Brit. 262,834 (C. A. 21, 4055) is replaced by high temp. coke which may be made by internal heating as described in Brit. 276,407 (C. A. 22, 2456).

Washing flue gases. M. PRETOT and F. ULLMANN. Brit. 281,651, Dec. 4, 1926. A soln. of soda or potash, or both, is used for scrubbing gases to remove solid particles. An app. is described comprising turbine blades which are caused to rotate by the flow of gas.

Scrubber for removing tar from gases produced by distillation of wood, peat, lignite, etc. H. HENNEBUTTE (to Soc. anon. la carbonite). Brit. 281,653, Dec. 2, 1926.

Gas retorts. STETTINER CHAMOTTE-FABRIK A.-G. VORM. DIDIER. Fr. 632,809, April 14, 1927. A door for a gas or coke retort is described.

Separating ammonia from gases. GES. FÜR LINDE'S EISMASCHINEN A.-G. Brit. 281,288, Nov. 27, 1926. Coke-oven gases or similar gases from which tar has been removed are compressed to 4 atm. and passed at a temp. of about 140° through a coil in a water column in which the temp. falls from 105° to 50°. C_6H_6 is continuously

discharged in liquid form through a valve and dil. NH_3 liquor passed into the gas stream entering a parallel-flow washer. A 10% NH_3 soln. collects in a separator and the gas at about 15° passes into a counter-flow washer to which a small quantity of water is supplied. Residual NH_3 is removed and the gas is further cooled to about -20° in a counter-flow cooler as described in Brit. 275,633 (*C. A.* 22, 2260) for removing C_4H_8 . Then, after passing through a separator, it is expanded and further cooled to -60° . App. is described comprising a column in which the ammonia liquor from the first-mentioned separator may be heated to evolve NH_3 , CO_2 and H_2S .

Determination of naphthalene in illuminating gas. WALTER H. FULWEILER (to The U. G. I. Contracting Co.). U. S. 1,678,591, July 24. An app. for detn. of C_{10}H_8 in gas comprises a pair of cond. cells provided with fixed electrodes and means accessible from the exterior of the cells to vary the capacity of the cells so that the consts. of the cells can be adjusted to equality.

Removing sulfur compounds from gases. E. B. MILLER and G. C. CONNOLLY (to Silica Gel Corporation). Brit. 280,947, Nov. 19, 1926. Gas such as coke-oven gas, water gas or producer gas is treated with air or other oxidant in the presence of solid adsorbent material carrying a metal oxide, e. g., silica gel impregnated with about 1% of Fe_2O_3 or CuO or both. Two layers of material may be used heated, resp., to 200 – 210° and 185 – 200° . A preliminary treatment at a higher temp. (suitably 450°) may be carried out to convert org. S compds. into H_2S .

Tar distillation. SOCIÉTÉ DES ÉTABLISSEMENTS BARBET. Fr. 632,256, July 17, 1926. See Brit. 274,513 (*C. A.* 22, 2260).

Treating tar. FREDERICK C. BUNGE and HEINRICH MACURA. Fr. 633,643, April 30, 1927. Crude tar or products sepd. therefrom are treated with halogen compds. which in the presence of OH or SH groups eliminate hydrazides. Such compds. include COCl_2 , BCl_3 , AcCl , BzCl or chlorides of P, Sn, Cr, S, Si, Sb, Bi, As.

Cracking oils and tars. I. G. FARBENIND. A.-G. Fr. 632,533, April 9, 1927. In a process for cracking oils and tars to obtain low-boiling or gaseous hydrocarbons, the oils or tars are heated by one or several elements immersed in the liquid which are heated electrically to the b. p. of the liquid and against which a current of gas contg. O or H or of gas free from C but capable of liberating H is directed.

Recovery of sulfuric acid from acid tar. C. STILL and FIRM OF C. STILL. Brit. 281,547, Dec. 22, 1926. In treating acid tar, produced in purifying "benzols" by treatment with H_2SO_4 , as described in Brit. 277,619 (*C. A.* 22, 2656), the acid tar is mixed with $(\text{NH}_4)_2\text{SO}_4$ soln. at a temp. of about 55° and the resins are not further heated until the aq. layer has been withdrawn. An app. is described.

Separating neutral products from tar. FRIEDRICH C. BUNGE. Fr. 633,542, Apr. 28, 1927. Crude tar is treated with phosphoric acid which takes up the acid products, and the neutral products sep.

Treatment of hydrocarbon residues. RALPH T. GOODWIN (to Standard Oil Development Co.). Can. 282,000, July 24, 1928. Pressure tar is stabilized by treatment with $1\frac{1}{2}\%$ to 1% by vol. of H_2SO_4 of 30 – 60° B \acute{e} , heating to 200 – 275° F. to ppt. sediment and sepg. the sediment.

Coke-oven construction. FOUNDATION OVEN CORP. *Brit. 281,403, Sept. 3, 1926.

Coke-oven construction. FOUNDATION OVEN CORP. Brit. 281,405, Sept. 3, 1926.

Coke-oven and quenching car construction. DR. C. OTTO & Co., Ges. Brit. 280,944, Nov. 22, 1926.

Vertical coke-oven construction. J. VAN ACKEREN (to Koppers Co.). Brit. 281,221, Nov. 27, 1926. Numerous structural features are specified.

Reversing valves for regenerative coke ovens. FOUNDATION OVEN CORP. Brit. 281,404, Sept. 3, 1926.

Quenching coke. FRANK F. MARQUARD. U. S. 1,677,973, July 24. The hot coke is intermittently sprayed with water for relatively short periods, between which it is permitted to drain and cool. An app. is described.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

F. M. ROGERS

Effect of volatility of petroleum fractions on detonation value. J. C. GENIESSE AND H. F. HUF. *Ind. Eng. Chem.* 20, 794-6(1928).—There is a definite relationship between the sp. gr. of a fraction from a given crude oil and its detonation value, and also between the 50% (including loss) distn. temp. of a fraction from a given crude oil and its detonation value. A graph constructed from those data makes it possible to predict what effect changing the volatility will have on the detonation value.

G. CALINGAERT

Unsaturated hydrocarbons in various petroleum products. III. G. GANE AND M. ZILISTEANU-GHEORGHIU. *Bul. soc. chim. Romania* 8, 3-10(1926); *Chem. Zentr.* 1927, II, 354-5.—In finishing a study of the I no. of petroleum products, a no. of lubricating oils from Roumanian refineries were analyzed, detns. being made of the d₁₅, flash point, viscosity, f. p. and I no. (by the Wijs method). As with light petroleum products, the I no. increased with increase in d. and b. p., i. e., with the mol. wt. The I nos. of crude distd. oils were higher than those of the corresponding refined oils, which shows that aromatic and hydroaromatic hydrocarbons, olefins and terpenes are partially removed by the refining process. To det. whether the I no. gives a quant. indication of the content of unsatd. hydrocarbons in a petroleum product, the unsatd. hydrocarbons were detd. with Hg(OAc)₂ by the method of Tauss (cf. Danaïla, Andrei and Melinescu, *Bul. chim. pura applicata* 26, 4). The method was previously tested with hexane + amylene, hexane + amylene + mesitylene, a normal benzene, and mixts. of the latter with the aforementioned hydrocarbons, and was found to be reliable. The aromatic hydrocarbons were detd. by the method of Böttcher and Krämer, 10 cc of sample being shaken for 30 min. with 30 cc. of H₂SO₄.H₂O, which destroys aromatic and unsatd. hydrocarbons, so that the former are detd. by difference. Since this method gave good results with the artificial mixts. above, unsatd. hydrocarbons in petroleum fractions were detd. Only with light fractions were satisfactory results obtained. In 1 fraction of d. 0.730 the method of Tauss showed 12.5% unsatd. hydrocarbons. With heavier oil the method failed to give good results, since the higher-boiling hydrocarbons do not distil with steam.

C. C. DAVIS

Use of the acetylene tetrachloride method of porosity determinations in petroleum engineering field studies. CHASE E. SUTTON. *Bur. Mines, Repts. of Investigations* No. 2876, 10 pp.(1928).—The vol. of a chunk sample of the oil sand 3 to 4 cc. in vol. is detd. by displacement of C₂H₂Cl₄ in a development of the Le Chatelier sp. gr. flask, adopted as the standard for detg. the sp. gr. of cement (Eckel, *C. A.* 17, 619), following the method suggested by Russell (*Bull. Am. Assocn. Petroleum Geol.* 10, 931(1926)). The sample is then crushed to its sep. grains and their vol. are detd. in the same manner as for the solid specimen. The percentage porosity, *P*, by vol. is given by the formula: $P = [(1 - V_2)/V_1]100$, in which *V*₁ and *V*₂ represent vol. of the solid specimen and the sand grains, resp. This method gives results sufficiently accurate for use in making an engineering study of underground conditions.

RAYMOND E. SCHAAED

Degree of wetting of silica by crude petroleum oils. F. E. BARTELL AND F. L. MILLER. *Univ. of Michigan. Ind. Eng. Chem.* 20, 738-42(1928).—The adhesion tension of different crude oils against silica has been detd., with a displacement cell app. similar to that of Bartell and Osterhof (cf. *C. A.* 22, 523). A simple app. was devised to measure the interfacial tension of H₂O against oil. The adhesion tension of different oils against silica was different, and the values ranged from approx. 58 to 72 dynes per cm.

T. S. CARSWELL

Dew points of air-gasoline mixtures from distillation curves. OSCAR C. BRIDGMAN. *Ind. Eng. Chem.* 20, 821-6(1928).—Gasoline was vaporized by a dynamic method in the presence of known quantities of air at temps. permitting successive approach to complete vaporization. For each mixt. and gasoline, the curve of temp. vs. percent evapd. extrapolated to 100% gave the dew-point temp. These equil. distn. values agreed well with values obtained by the method of Stevenson and Babor (cf. *C. A.* 22, 1032), and with the results of these investigators. The dew-point temps. at 1 atm. pressure, of gasoline vapor and of mixts. from 1:1 to 30:1, were found to be simply related to the 90% A. S. T. M. points, corrected for loss, and to each other.

G. CALINGAERT

Sulfur toleration in gasoline. G. EGLOFF AND C. D. LOWRY, JR. *Ind. Eng. Chem.* 20, 839-43(1928).—An analysis of gasoline consumption in relation to temp.

shows that over $\frac{2}{3}$ of the country's total consumption is used in warm weather, when there is no danger of corrosion. The sulfur tolerance in gasoline should be regulated by climatic conditions. In warm weather the sulfur limitation might be revoked entirely. Also in *Oil & Gas J.* 27, No. 12, 152, 163 (1928). G. CALINGAERT

Estimation of benzene in petrol (gasoline). STANLEY KETTLE. *Chemist-Analyst* 17, No. 3, 14(1928).—Shake 20 cc. of the gasoline in a stoppered bottle with a small quantity of one of the indanthrene blues for 2 hrs. Filter into a tall glass cylinder standing on white paper. Compare the color with that obtained from known mixts. of benzene and gasoline similarly treated. W. T. H.

Antiknock compounds. J. H. FRYDLENDER. *Rev. prod. chim.* 31, 361-4(1928).—The problem of knocking is reviewed. The anti-knock power of different compds. is compared and the manuf. and properties of $PbEt_4$ and of Fe carbonyl are described. P. THOMASSET

Engine knock and related problems. ALFRED C. EGERTON. Univ. of Oxford. *Proc. Roy. Inst. Gr. Brit.* 1928, 15 pp.; cf. C. A. 22, 1034.—Previous work (E. and Gates, C. A. 21, 2065; 22, 870) shows that the presence of antiknock compds. does not influence the position of detonation at ordinary pressure in a tube in C_2H_6 , C_4H_{10} and H mixts. dild. with A, N and CO_2 . In a long electrically heated tube provided with glass windows, increase of pressure diminishes the distance from the spark at which detonation starts up to a limiting pressure above which further increase has little effect. E. confirms Weerman (C. A. 21, 2555) in that antiknock compds. raise the ignition temp. (I. T.) of gasoline in air. The ignition-inhibiting properties of metallic vapors have been detd. by Weerman by bringing them from an arc between the metallic electrodes in an A stream into an electrically heated pot provided with a thermocouple for measuring the I. T. The metals most effective in increasing the I. T. fall in the order: Ti, K, Pb, Fe, Ni, Mn, Bi, Se, Te, Na, Cd, Ca and Sb. The ineffective elements are: Al, Mg, Hg, I, P, Au and Zn. The following metals have a doubtful effect: Sn, Ce, V, Ti, Zr, Th, Ta, W, Cr, Co and U. Antiknock substances appear to "have the common property that a state of equil. exists at the temp. at which they operate between certain products of the antiknock." In the case of K the oxides K_2O_3 and K_2O_4 have been shown to exist in a state of equil. in favor of the higher oxide at 400°. This oxide if reduced to the lower can be regenerated by the next suitable impact with an O mol. Peroxide formation (cf. Callendar, C. A. 21, 1697) with the production of centers of high energy is considered as the initial stage in the combustion of a hydrocarbon mol. Antiknock substances inhibit (cf. E. and Gates, C. A. 21, 2554) the oxidation of fuels prior to ignition evidently by breaking the reaction chains. This view is supported by Bäckström's application of the chain reaction theory (C. A. 21, 2835; 22, 717) to work on the thermal oxidation of liquid aldehydes and by Hinshelwood's explanation (*Proc. Roy. Soc. (London)* A118, 170-83(1928)) of his measurements of the rate of reaction of H and O. Also in *Nature* 122, 20-6(1928).

RAYMOND E. SCHAAD

Lubrication. Round table discussion. D. P. BARNARD, 4TH, et al. *Ind. Eng. Chem.* 20, 843-9(1928).—The main part of the paper has been published elsewhere (*J. Soc. Automotive Eng.* 22, 213(1928)). The ensuing discussion covers the influence of the pour point of oils on circulation at low temp., the effect of the surrounding atm. (air or H_2) on the friction on a bearing, and the advantage of greases melting above 320° F. over oils, as lubricants for steam-engine cylinders and journals. G. C.

Kaluga petroleum as a lubricating material. M. RAKITIN. *Nefityanoe Khozyaistvo* 12, 705-6; *Chem. Zentr.* 1927, II, 1916. E. H.

The fundamentals of semiliquid friction. S. KIESSKALT. *Z. tech. Physik* 9, 207-12(1928).—A review with 24 references of the literature of lubrication. It is concluded that the "oiliness" of lubricating oils is a function not of their surface tension against air but of the adsorption on bearing metals and of the relation between viscosity and pressure. Lubrication is a boundary phase problem. B. J. C. VAN DER HOEVEN

The alteration test of transformer oils. SOCIÉTÉ DES HUILES DE CAVEL ET ROEGIER. *Bull. fed. ind. chim. Belg.* 7, 249-59(1928).—The temp. required by the Belgian test, 170°, is too high. A test at 120° should be adopted. A. L. HENNE

Experimental oil-shale plant of the Bureau of Mines. MARTIN J. GAVIN. *Ind. Eng. Chem.* 20, 784-91(1928); cf. C. A. 21, 316.—The exptl. oil-shale plant operated by the U. S. Bureau of Mines at Rulison, Colo., during 1926 and 1927 is described. Two retorts are used for producing oil, a standard Pumpherson retort (C. A. 17, 1711) of the size and type in com. use in Scotland for 25 yrs. and a N-T-U retort, of approx. 25 tons charging capacity, similar to the units used by the N-T-U Co. at Casmalia, Calif. The analyses given show that the oils produced by the 2 retorts are essentially

similar except that the Pumpherstons oil contains a greater amt. of secondary decompn. products and is lighter. By a combination of topping and cracking operations, 52% of motor fuel, final b. p. 437° F., has been made from the N-T-U crude oil and 64% from the other. The cracked fuel from the Pumpherstons crude oil has the higher antiknock rating.

RAYMOND E. SCHAAD

Oil shale developments in Canada. A. A. SWINNERTON. *Can. Chem. Met.* 12, 220-3 (1928).

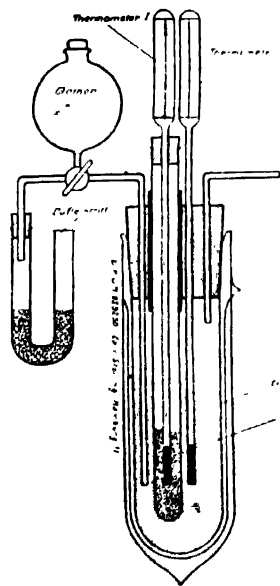

Dossor mineral oil. B. G. TUICHININ AND S. N. PAVLOVA. *Papers Karpon Chem. Inst. Bach. Memorial Vol.* 1927, 215-29.—The Dossor oil fields (in Caucasus) are disposed in 3 horizontal layers of which the 1st (upper) is not productive. The other 2 are productive and consist of asphalt-base oils contg. but very little paraffin. The oil of the 2nd layer has no benzene fraction, almost no kerosene fraction and is thick and viscous; the oil of the 3rd layer contains all the fractions. Most of the detns. were made not on the original oils, but on the mazouts obtained after distg. off the portion boiling below 300°, at which temp. they do not suffer decompn. The mazouts obtained from all the samples of the 2nd layer possess almost identical const., a circumstance which shows that the differences of the original samples taken from that layer were only due to differences in the degree of evapn. The samples of the 3rd layer have lesser sp. gr., lesser viscosity and contain less tarry asphalt than the samples of the 2nd layer. They give less mazout than those of the 2nd layer, and their mazout is lighter by 0.01-0.02 and possesses less viscosity. It is thus evident that the oil of the 3rd layer is a different oil from that of the 2nd layer since the difference between them is not merely a difference in the degree of evapn. Moreover, all the samples taken from different faults of the 3rd layer are not similar; there must have been at some spots infiltrations of the upper (heavier) oil into the lower layer. The S content is approx. the same for oils of both horizontal layers; when distg. the oils it is found that the S content increases with the b. p. of the fraction, and its max. is in the residue. The acidity and the N content also increase with the b. p. of the fraction. The content of N bases of the samples of the 3rd layer (0.016%) is about 5 times as large as that of the second layer.

BERNARD NELSON

Improved cold point apparatus for mineral oils.

ANON. *Chem.-Ztg.* 52, 520 (1928).—The app. (see fig.) is used as follows: in a first test, the air current sucked by the pump is so regulated that the temp. difference between the ether and the oil is about 5°. In a second test, the temp. difference is regulated at only 1° as soon as the cold point is approached.

A. L. HENNE

Paraffin tar. V. TVERZIN. *Neftyanoe Khozyaistvo* 11, 732-7 (1926); *Chem. Zentr.* 1927, 1, 2380-1.—Paraffin tar is the residue after distn. of 85% of the petroleum from the distn. of Grosnyi petroleum (which contains paraffin). Its f. p. (Holde) is approx. 50° and its d_4^{20} 0.986. It contains ceresin wax, but no paraffin. When oxidized with air at 250-80° it yields asphalt tar, which softens at 85-90°. Paraffin tar contains 10-13% and asphalt tar contains 20% asphaltene (benzene-insol.), which mixed with rosin or turpentine oil forms black varnishes or insulating materials. From the part of the paraffin tar remaining after removal of asphaltenes, vaseline is prepd. To this end it is treated 3 times with 0.5 part of SiO_2 gel which has been first satd. with HCl. The orange-yellow vaseline obtained can be almost decolorized with fuller's earth. The viscosities of the vaseline and of the viscosine are obtained by distg. off the lighter components between 50° and 150°. The difference in viscosities

of these products diminishes greatly with increasing temp. At 150°, at which viscosine is used, its viscosity is only slightly greater than that of vaseline. The advisability of producing viscosine is therefore doubtful. The adsorption of rosin from paraffin tar freed of asphaltenes by filtration through SiO_2 gel was measured. The adsorbing agent can be regenerated 5 times by extrn. with a mixt. of EtOH and C_6H_6 , but further regeneration is possible only through ignition.

C. C. DAVIS

Filter for lubricating oils, etc. (Brit. pat. 281,124) (U. S. pat. 1,677,892) 1. Agitator for mixing oil with chemicals (U. S. pat. 1,678,225) 1.

Cracking oils. HÉLIDOR ROSTIN. Fr. 633,127, Aug. 4, 1926. Oils are passed at a high temp. in the presence of H_2S over metals capable of combining with the S of the H_2S and liberating H, particularly alloys of Cu with Zn, Bi, Al or Fe. The metal may be regenerated by passing H or gases contg. H over it at a higher temp.

Cracking oils, etc. I. G. FARBENIND. A.-G. Fr. 632,850, Mar. 29, 1927. To avoid a deposition of C in cracking oils, the metals Co, Cr, Ni, Mn, W, Mo, Ti, Cb, Ta, Th, U, Cu, Tl and their alloys are used in the heated zone. Catalysts such as oxides or sulfides of Fe, Ni or Co may be used in the process. Cf. C. A. 22, 1847.

Cracking hydrocarbons. HENRI MARCHAND. Fr. 633,133, Aug. 5, 1926. See Brit. 275,642 (C. A. 22, 2222).

Cracking hydrocarbon oils. JAMES M. SCHOONMAKER, JR. (to The Texas Co.). U. S. 1,678,126, July 24. An app. is described in which cracking is inhibited during preliminary heating by applying pressure on the oil additional to the vapor pressure of the oil. After this heating under vapor and additional applied pressure, the oil is cracked by a reduction of pressure and further heating.

Purification of oil gases. CONSTANTIN CHILOWSKY. Fr. 632,499, Apr. 8, 1927. An app. is described for purifying gases produced by the pyrogenic transformation of heavy oils in which the temp. is maintained sufficiently high in the generator to avoid condensation of tars, and the gas is suddenly submitted on leaving the generator to a temp. below that of the condensation of the tars.

Purifying hydrocarbon oils with liquid sulfur dioxide. ALLGEMEINE GES. FÜR CHEMISCHE INDUSTRIE. Brit. 281,337, Nov. 26, 1926. A jet app. is used to produce reduced pressures and to cool the liquefied SO_2 . Cf. C. A. 22, 3042.

Treatment of hydrocarbon oils. HOWARD T. WRIGHT and FRED ESLING. Can. 281,879, July 24, 1928. Oil is preheated under pressure which inhibits vaporization and cracking, then a portion of the oil is sepd. by vaporization under temp. and pressure which inhibit cracking, the vapor is cracked, expanded into a region of relatively reduced pressure and its heavier fractions are condensed. The resulting condensate is an oil with a range of boiling points, substantially included in the boiling point range of the original stock. The condensate is cyclicly retreated.

Treatment of hydrocarbons. LOUIS BOURDELLES. Fr. 632,378, July 23, 1926. To obtain oils, heavy hydrocarbons are desulfurized and hydrogenated simultaneously by causing them to enter in the form of vapor or pulverized and mixed with a large vol. of steam, a vessel contg. divided metals heated to between 350° and 450° at approx. atm. pressure and which are regenerated periodically by changing the compn. of the vapors by the simple operation of valves.

Separating hydrocarbons by centrifuges. SOC. BERGENDORFER EISENWERK A.-G. Fr. 632,602, Apr. 11, 1927. To sep. liquid hydrocarbons by centrifuging from hydrocarbons which solidify on cooling, a liquid which is easily sol. in or readily dissolves the liquid hydrocarbons but does not dissolve the hydrocarbons to be sepd. is added to the mixt. during or after cooling, the sp. gr. of the said liquid being higher than that of the heaviest hydrocarbons to be sepd. C_2HCl_3 , C_2Cl_4 and CCl_4 are suitable liquids and hydrocarbons of a low viscosity may be added to them.

Oxidizing hydrocarbons. RHETHERFORD B. MARTIN (to Minerals Separation North American Corp.). U. S. 1,678,403, July 24. A continuous stream of vaporized hydrocarbon material such as a heavy petroleum distillate mixed with O is passed under the influence of ultra-violet rays to produce oxidation products such as are suitable for use as *frath flotation agents*. An app. is described.

Oil-shale treatment. JAMES N. VANDERGRIFF (to The American Shale Reduction Co.). Can. 282,120, July 31, 1928. Oil shale is heated to a temp. at which the volatile matter is about to be vaporized, then suddenly heated to an increased temp. to drive off the volatile matter in a body. The pyrobitumen or hydrocarbon element of the material treated is cracked, yielding products of lower sp. gr. than if vaporized at normal vaporizing temp. The unsatd. cracked vapors are hydrogenated by the H released from the decompn. of steam generated from the moisture of the shale. The hydrocarbon vapors before leaving the retort are catalyzed by passing through a shower of incandescent spent shale which takes up the excess of C in the vapors. The final product has a high percentage of satd. hydrocarbons.

Apparatus for oil-shale treatment. JAMES N. VANDERGRIFF (to The American Shale Reduction Co.). Can. 282,119, July 31, 1928. App. for the above process is specified.

Refining oils. WALTER A. PATRICK and ERNEST B. MILLER (to The Silica Gel Corp.). U. S. 1,678,298, July 24. An oil such as gasoline or kerosene is treated with a solid adsorbent material, *e. g.*, silica gel, having pores of such size that it will adsorb water vapor to such an extent as to contain not less than about 10% of its own wt. of water when in equil. with water vapor at 30° and a partial pressure of about 22 mm. Hg. An app. is described. U. S. 1,678,299 (E. B. MILLER) relates to app. for similar purposes.

Temperature-control system for separating towers used in petroleum-oil distillation, etc. RICHARD H. CARR and CORNELIUS B. WATSON (to Pure Oil Co.). U. S. 1,678,328, July 24. A preheater is placed in the tower and connections are provided for passing oil stock through the preheater or through a by-pass by automatic control according to the internal temp. of the tower

Mineral oils from peat, lignite, etc. CONSTANTIJN W. M. Bervoets. Fr. 633,623, Apr. 30, 1927. Mineral oils of the nature of gasoline are produced by the action of microorganisms on peat, lignite and other bituminous substances under favorable conditions for the growth of the microorganisms.

Sulfonating oils. I. G. FARBERNIND, A.-G. Fr. 632,633, April 11, 1927. Mineral oils, with the exception of coal tar oils, are sulfonated by means of chlorosulfonic acid. Examples are given of the sulfonation of solar oil, solar oil in solvent naphtha or chloro benzene and yellow oil in tetrahydronaphthalene. The products are wetting, emulsifying, etc., agents.

Heavy oil for furnaces. CHARLES PERDRISAT. Fr. 632,817, April 15, 1927. An app. is described for firing heavy oils for furnaces of different kinds.

Device for regulating oil burners, etc., automatically by temperature and pressure controls. SYNTHETIC AMMONIA & NITRATES, LTD., and F. E. SMITH. Brit. 280,977, June 21, 1926.

Improvements in oil burners. ALPHONSE KESSLER. Fr. 632,702, April 13, 1927.

Burners for liquid fuel, particularly mazout. JEAN A. FAUKE-HERMAN. Fr. 633,487, April 27, 1927.

Burner for insertion into oil wells to increase their production. JAMES B. GARNER and GEORGE B. LEYDEN (to Standard Oil Development Co.). U. S. 1,678,592, July 24

Thermostatic and safety control device for oil burners of domestic or other heating systems. I. E. McCABE. Brit. 281,619, Dec. 6, 1926.

Lubricants. A. HORN. Brit. 281,476, July 19, 1927. Oils such as castor oil are rendered water-sol. and miscible in all proportions with mineral oils by heating to about 300°, allowing the oil to cool, reheating to 100–110° and treating with gaseous HCl in the presence of a catalyst such as anhydrous AlCl₃, blowing with O, air or ozone at 150–200° until free from HCl and further blowing at 200° with addition of an alkali hydroxide, carbonate, percarbonate, or perborate or SnCl₂ or an org. compd. such as resorcinol, pyridine, quinone, hydroquinone, quinoline, hydroxylamine or trimethylamine. The polymerized products thus obtained may be neutralized at 50–60° with inorg. or org. bases and clarified by passing through a filter of clay coated with basic Zn acetate or Zn borate.

Apparatus for the carbonization of wood and for the distillation of wood and other substances. JEAN BONELLO and PIERRE AUBÉ. Fr. 632,377, July 23, 1926.

Lead acetate. MAX KLAR. Fr. 632,866, April 15, 1927. Lead acetate is obtained directly from pyroligneous acid from the dry distn. of wood, and impurities such as lead butyrate, condensation products of aldehydes, etc., are removed by activated carbon. Cf. following abstract.

White lead acetate from pyroligneous acid. MAX KLAR. U. S. 1,678,256, July 24. Pyroligneous acid is neutralized with Pb or a suitable Pb compd. and Pb acetate in solid form is produced from the resulting soln.; the solid Pb acetate is heated to 200–220° to render org. coloring impurities insol. in water, and the material is lixiviated with water, the soln. is filtered and crystn. is effected to obtain purified Pb acetate.

Methyleugenol. WILLIAM G. ANDREWARTHA. U. S. 1,678,416, July 24. The mill waste and topplings of Huon pine timber are treated in a closed vessel with steam under pressure for about 2 hrs. and the vapor is educted and condensed and water is sep'd. from the condensate.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Some recent developments in the cellulose industry. C. J. J. FOX AND L. HALL. *Kunstseide* 10, 10-12(1928).—A review of a paper by Cross and Bevan, giving a general discussion of recent developments in the production of cellulose and in the manuf. and application of various cellulosic products

FREDERICK C. HAHN

Degradation of cellulose by sulfite acid. W. H. BIRCHARD. *J. Soc. Chem. Ind.* 47, 49-52T(1928).—Bleached and unbleached sulfite and rag pulp, bleached soda and straw pulp, alpha fiber, and raw and purified cotton were subjected to regular sulfite cooks in an autoclave. Analysis showed that the purer the original material the greater the decrease in α -cellulose on cooking, raw sulfite losing 1%, pure cotton 30%. Microscopic examn. showed a loss in fiber length of 69-88%, but no loss in diam. Apparently the β - and γ -celluloses (dextrins and anhydro-sugars) present protect the cellulose to a greater or less extent, depending on the amt. present. The sulfite liquor in cooking breaks the cellulose mol. down into 2 compds., called β - and γ -celluloses, the reaction reaching an equil. which is maintained until the β - or γ -cellulose is destroyed. In agreement with this, β -cellulose was not affected by cooking, while pure α -cellulose was so degraded that it could not be analyzed. The fact that poplar pulp does not fit correctly into the above scheme is explained as due to the greater soly. and consequent smaller protective action of the sugars in this pulp. Mention is made of the appearance of microscopic crystals on dried slides of the recooked straw pulp, which had been thoroughly washed with distd. H_2O .

R. H. DOUGHTY

Mercerization of sulfite cellulose. II. V. I. SHAROV. *J. Chem. Ind. (Moscow)* 4, 666 8(1927); cf. C. A. 22, 2837.—Mercerization is influenced by many factors: temp., kind of alkali, presence of salts and of alcs., properties and purity of the cellulose used. KCNS is capable of mercerizing cellulose. When a mixt. of KOH and KCNS is used the effect on cellulose at lower temp. is incomparably greater than that of either of the 2 components of the mixt.; at higher temp., however, the swelling decreases; also the contrary might be supposed in view of the circumstance that hot KCNS can dissolve cellulose. Aq. LiOH has a powerful swelling effect on cellulose. B. N.

Metallic complexes of cellulose nitrate. A. APARD. *Mem. poudres* 23, 63-8 (1928).—See C. A. 22, 1511.

A. J. PHILLIPS

Dyeing celluloid. ADOLF GEBHARDT. *Deut. Färber Ztg.; Dyer, Calico Printer* 60, 34(1928).—A general description is given of the dyeing of celluloid in the production process as well as the finished product.

RUBY K. WORNER

Recent progress in the manufacture of artificial silk. J. V. G. *Rev. chim ind.* 37, 186-400(1928).—The improvements in the manuf. of silk by the different processes now in use are discussed. One of the major factors is the use of a cellulose containing a high percentage of α -cellulose.

P. THOMASSET

Investigations on viscose. MASAHARU NUMA. *Kunstseide* 9, 597-9(1928); cf. C. A. 22, 2464.—A review of work conducted on viscose at the Tokyo Imperial Ind. Lab. (see work of G. Kita and co-workers, C. A. 20, 2247-8; 21, 3457-8). Mention is made of a new method for the detn. of combined S in cellulose xanthate, which consists in treating cellulose xanthate, purified with AcOH and satd. NaCl soln., with NaOCl soln. contg. 5% available Cl and decompg. with HCl (sp. gr. 1.06), and, after 10 min., detg. H_2SO_4 by the usual method.

FREDERICK C. HAHN

Developments in the preparation of calcium-magnesium bisulfite liquors. D. W. STEWART. National Research Council, Ottawa. *Can. Chem. Met.* 12, 227(1928).

E. H.

Methods of analysis for black liquor and sulfite cooking liquors. E. ÖMAN. *Tek. Tidskr. Kemi.* 57, 51(1927).—For NaOH, 25 cc. liquor is dild. to 250 cc. with 95% EtOH and the mixt. allowed to settle to complete clarification (2 to 3 hrs.) 25 cc. of the alc. soln. is titrated with 0.1 N HCl, Nile blue (sulfate) being used as indicator. The purity of the alc. and the time of settling must be followed unconditionally. Other alcs. gave negative results. The usual method of pptg. with $BaCl_2$ is not accurate because of the large amt. of NaOH absorbed by the ppt. This method detcs. NaOH + $\frac{1}{2} Na_2S$ and about 10% of the Na_2CO_3 , if present. For Na_2S , 25 cc. of the alc. soln. is added to 300 cc. water contg. about 5 cc. 2 N acid, and titrated with I. For total S, 25 cc. black liquor is heated with an equal vol. of red, fuming HNO_3 in a distn. flask, and the gases are condensed. Heating is continued until the liquor becomes clear. The distillate is added to the liquor and the S detd. by $BaCl_2$. To show the presence of polysulfides in white liquor, \bar{O} . agitated the liquor with an excess of 95% EtOH in a

separatory funnel and obtained a yellow oil, which was sol. in water and yielded H_2S and free S on acidification. The polysulfides may be estd. by filtering, washing and drying the pptd S. When white liquor and black liquor are mixed a reaction takes place between the org. material in the black liquor and the free alkali in the white liquor. The free alkali concn. decreases considerably, lessening the severity of the chem. action on the fiber. During cooking more org. material is brought into soln., further decreasing the alk. concn. Lightly bound NaOH is liberated, aiding the digestion. The org. material also acts as a buffer for the free alkali. The relative proportions of combined and free alkali vary with the temp. The org. material reacts also with Na_2S , the reaction being dependent upon the time and the concn. of NaOH in the black liquor. C. F. PATERSON

Wood and pulp. ARTHUR ST. KLEIN. *Wochbl. Papierfabr.* 59, Sondernummer 23A, 60-7(1928).—A general review, covering the subjects of wood supply and forest management, the nature of wood substance, cellulose and lignin, and pulping processes, with numerous references to the more recent literature. R. H. DOUGHTY

Pulp freeness and the alkali solubility of pulp slimes. C. G. SCHWALBE. *Wochbl. Papierfabr.* 59, Sondernummer 23A, 107-8(1928).—There is a relation between alkali soly. and Schopper-Riegler freeness, which may be adapted to control testing. Soly. values of pulp beaten to a given freeness in a Lampen mill are lower than when the pulp is treated in the beater. The alkali-sol. material is detd. by treating a 15-g. sample with 30% NaOH and water to make a total vol. of 150 cc. 16% NaOH, pptg. the dissolved material in an aliquot with HNO_3 , adding EtOH, centrifuging for a standard time and measuring the vol. of ppt. R. H. DOUGHTY

Bleaching sulfite pulp. L. RYS. *Papier-Fabr.* 26, 256-60, 269-75, 288-9(1928); cf. C. A. 22, 2271; 21, 1711.—A large no. of lab.-scale expts. have shown that sulfite pulp is most efficiently bleached in 2 stages, using Cl water in the first and hypochlorite in the second, the ratio of active bleaching agent in the 2 stages being 3 or 4 to 1. If the pulp is treated before each stage with alkali equal to 0.5-1.0% of its wt., and thoroughly washed, the action is still further improved. This alk. extn. removes partially bleached products which are only sparingly sol. in water. Milk of lime is as effective an extn. agent as NaOH; SO_2 (sulfite liquor) soln. is valueless; addn. of bleach to the alk. soln. is of no advantage. The entire bleach is carried out at low density, the first stage at room temp., the second at about 35°. The saving in bleach over a one-stage bleaching with hypochlorite may reach 30%, being greater the more difficultly bleachable the pulp. This saving is as great as can be obtained by bleaching in 2 stages at high density. The time also is no longer than for a 2-stage high-density bleach, and might well be shortened further by catalytic acceleration in the second stage (cf. C. A. 21, 1361). The pulp produced is better in color and chem. quality than can be obtained by bleaching with hypochlorite alone under any conditions. The difficultly sol. chlorinated products formed with Cl water are also formed in bleaching with hypochlorite, but in the latter case are rapidly attacked and broken down to sol. compds., because of the alk. and strongly oxidizing nature of the soln. Since the chlorination is greater at high density, an intermediate alk. extn. should be of value in 2 stage high-density bleaching. The bleached pulps were compared for color and general purity by means of their fluorescence in ultra-violet light. Pure cellulose fluoresces a clear blue-violet, while an entirely unbleached pulp is brown. Very fine gradations in purity are clearly evident, and may be recorded photographically. R. H. DOUGHTY

A new liquor tower for sulfite pulp mills. ALOIS DANNINGER. *Wochbl. Papierfabr.* 59, Sondernummer 23A, 76-8(1928).—Three wooden towers 8 ft. in diam. are enclosed by a large iron tower, to combine max. strength, protection from weathering and acid resistance. R. H. DOUGHTY

Sulfite pulp from spruce. RAGNAR BERGQVIST. *Papier-Fabr.* 26, 440-6(1928); cf. C. A. 22, 2054.—The chem. theories of sulfite pulping (cf. Hagglund, C. A. 20, 284; Miller and Swanson, C. A. 20, 1516; Birchard, C. A. 21, 4064; 22, 084) are discussed and correlated. The cooking process may be divided into 3 steps: (I) Penetration period, from start of cook up to 100°, during which the liquor enters the chips, and sulfite addition compds. with lignin are formed. Even penetration is imperative for uniform cooking. (II) Alk. period, alkalinity being due to complete hydrolysis of sulfite to SO_3 and free base above 100° (Birchard). Carbohydrates and ligninsulfonic acids are dissolved during this period. Since temp. and OH-ion concn. are lower than in an alk. cook, the action is milder. (III) Third period, beginning when the free base is all consumed; the pH decreases slowly at first and then more rapidly, during this period, and must be closely followed if "burnt cooks" are to be avoided. The H-ion concn. of the cooking liquor appears to be a controlling factor throughout the

process. According to observations by B., resins are saponified during (II) by the free base, and reprecipitated during (III) on the fibers. The resin content during one cook decreased from 0.70% at 13 hrs. to 0.35% at 16 hrs. and rose to 0.86% at 17½ hrs. It is also suggested that the bad effect of sulfate in cooking is due to deposition of CaSO_4 in the chips, as the temp. rises, preventing penetration. R. H. DOUGHTY

Refiner calculations. N. WUNDERLICH. *Wochbl. Papierfabr.* 59, 374-7 (1928).—A mathematical analysis of the operation of the centrifugal or rotary pulp screen. The inlet conditions are more important than is generally realized; by proper subdivision of the streams at the inlet both capacity and efficiency of the machine can be increased. R. H. DOUGHTY

Synthesis of alpha spruce lignin. PETER KLASON. *Papier-Fabr.* 26, 208-11 (1928).—See C. A. 22, 1361, 1680. R. H. DOUGHTY

The size of paper fibers. PAUL KLEMM. *Wochbl. Papierfabr.* 59, Sondernummer 23A, 88-95 (1928).—The effects of length, diam. and length-diam. ratio on the character of the paper sheet are discussed theoretically. A closer study of this matter is a necessary step toward a better understanding of the relation between pulp quality, paper structure and paper quality. The present paper aims to prepare the way for such a study. R. H. DOUGHTY

Processes for the use of starch in paper. HANS WREDE. *Papier-Fabr.* 26, 301-9 (1928).—A comprehensive discussion of the importance of starch in paper, the characteristics of starch, its prepn for use and application in the beater to a variety of papers. R. H. DOUGHTY

The degree of dispersion and whiteness of paper fillers. RUDOLF LORENZ AND OTTO SEIDEREK. *Wochbl. Papierfabr.* 59, 201-5, 319-21, 377-9, 458-63 (1928).—Size-of-particle distribution for over 30 com fillers, including talc, kaolin, china clay, gypsum and blanc fixe, were detd., by an improved form of Wiegner-Gessner sedimentation app. The theory of such measurements is considered in detail (cf. also Lorenz, C. A. 20, 1519, 2746, for details of app. and theory of filling). Exptl. results confirm the general conception of the importance of degree of dispersion. Fillers may be coagulated by natural salts in water, by alum or by rosin size. NH_4OH tends to peptize them. The electrostatic theory of sizing also applies to filling; alum acts on negatively charged fillers in the same way as on size. Though the actual particle size of gypsum, as detd. in 50% glycerol-water suspension, is as small as that of kaolin, it is impossible to get a very high finish with gypsum fillers, because of rapid self-coagulation in H_2O . The same is true of blanc fixe. It is recommended that the latter be prepd. in the beater by adding rosin size, BaCl_2 and alum in the order named, with Na_2SO_4 if much ppt. is desired. Whiteness, as detd. by the Ostwald half-shade photometer, was, in %: blanc fixe >99, gypsum 99-93, china clay 94-88, kaolin 90-75, talc 95-49, the most highly dispersed samples showing the highest whiteness. The methods described furnish an accurate numerical expression of filler quality. R. H. D.

The change of breaking length, stretch, folding (and bursting) strength, and degree of sizing, with degree of finish of paper. V. POSSANER. *Papier-Fabr.* 26, 453-62 (1928).—Seventeen papers ranging from newsprint to rag bond were tested in the machine-finished condition and after 3, 6, 12 and 18 passes through a calender with a pressure of 150 kg./cm. A com. finish was given by 12 passes. The results are presented in detailed graphical and tabular form. Papers less than 60 g./sq. m. in wt. or those contg. much groundwood show but little increase in strength with increasing finish. Thicker papers and those contg. less groundwood show 5-6% increase in breaking length. Heavy papers, or those made of pure cellulose, whether wood pulp, straw pulp or rag, show increases of 9-11%. Stretch generally increased 20-30%, folds 30-50%, occasionally 100% or more. Burst increased 15-35%. A more free stock, or one contg. more ash, gave a smaller increase in strength values. The degree of sizing decreases to 70-10% of its original value on calendering. This is ascribed to breaking of the thin film of size which coats the fibers: a parallelism is drawn with glaze cracks in pottery. Repeated calendering of a few samples showed that the strength finally reached a const. high value, and did not tend to decrease. R. H. DOUGHTY

Valuation of rosin [for paper manufacture] (FILIPOVICH, TUKHOVITSEV) 26. **Estimation of starches [in bond papers]** (BOAST) 28. **Tanning materials [from cellulose waste]** (CASABURI) 29. **Determination of organic matter in mixed acid and of carbon in nitrocellulose** (CARRIERE, GILBERT) 7. **Determination of nitrites in nitrocellulose** (KOEHLER, MARQUEYROL) 7. **Detection of S and H_2SO_4** (NOLL) 7. **The uneven nitration of nitrocellulose** (BENEDICT) 26. **The status of lignin research** (JONAS) 10. **Apparatus for treating wood** (Fr. pat. 633,458) 20.

Cellulose esters. COURTAULDS, LTD. Fr. 632,636, April 11, 1927. Cellulose to be acetylated is treated with NaOH and then with a phenolic compd. such as phenol or *m*-cresol.

Cellulose esters. CAMILLE DREYFUS. Fr. 632,614, April 11, 1927. Phosphoric acid or mixts. of phosphoric acids with or without other catalysts are used in the esterification of cellulose in place of H_2SO_4 . The esterification is carried out in suspension by adding pptg. agents such as benzene or using the phosphoric acid in such strength that the ester does not dissolve. Fabric contg. cellulose or its derivs. may be so treated, after which it does not rot on exposure to sea air. Fr. 632,615 describes the esterification of cellulose by means of org. acids without the use of anhydrides or chlorides in the presence of a phosphoric acid, especially H_3PO_4 .

Cellulose ethers. CAMILLE DREYFUS. Fr. 632,616, April 11, 1927. Cellulose ethers, such as the Me, Et, Ph ethers or mixed ethers, are formed in the presence of phosphoric acids, especially H_3PO_4 with or without other catalysts.

Cellulose acetate. VERRIN CHEM. IND. A.-G. Fr. 632,619, April 11, 1927. See Brit. 269,543 (*C. A.* 22, 1473).

Cellulose derivative. GEORGE A. RICHTER, MILTON O. SCHUR and ROYAL H. RASCH (to The Brown Co.). Can. 281,946, July 24, 1928. Bleached wood fiber high in α -cellulose is treated with a soln. of caustic soda of mercerizing strength, the mercerized fiber is washed, acidified and again washed, dried and converted into cellulose derivs.

Cellulose derivative. GEORGE A. RICHTER, MILTON O. SCHUR and ROYAL H. RASCH (to The Brown Co.). Can. 281,947, July 24, 1928. Wood pulp high in α -cellulose is formed into nitration tissue, nitrated, the nitrocellulose dissolved and a nitro-cellulose product formed from said soln.

Cellulose for nitrocellulose manufacture. I. G. FARHENIND. A.-G. Brit. 280,922, Nov. 22, 1926. Cellulose is prepd. for use in making nitrocellulose by heating with water at 140–170° for a prolonged time (suitably 6 hrs.) to enable the production of nitrocellulose of desired viscosity characteristics suitable for use in making *varnishes*.

Drying cellulose films. ERNEST MULLER. Fr. 633,339, April 26, 1927. The films are dried by passing over rollers heated with H_2O , etc., and placed close together so that the surface in contact with one roller becomes exposed to the air on the next.

Swelling and loading treatment of cellulose ester films, etc. H. DREYFUS. Brit. 281,084, May 26, 1926. Fibers, films or ribbons of cellulose ester compn. or water-resistant cellulose ethers or condensation products of cellulose with polyhydric alcs. are rendered more absorbent of loading substances and their resistance to "laddering" is increased by preliminary treatment with swelling agents such as aq. glycolic acid, lactic acid, EtOH, acetone, diacetone alc., diacetyl, phenol, hydroquinone or NH_4CNS or other suitable thiocyanate; they may be further treated with loading reagents such as salts of Sn, Zn, Al, Bi, W or Sb followed by treatment with tannic acid, a phosphate or silicate or other pptg. agent.

Reduction of viscosity of cellulose esters. CAMILLE DREYFUS and GEORGE SCHNEIDER (to Camille Dreyfus). Can. 282,185, July 31, 1928. Cellulose acetate of low viscosity is obtained by acetylating cellulose in a porcelain vessel with a mixt. of 300 parts of AcOH, 400 parts of Ac_2O and 5 to 15 parts of H_2SO_4 contg. 0.2 part of $Fe(OAc)_2$, adding 25 parts of H_2O_2 (3%) after the completion of the acetylation and allowing the cellulose acetate to hydrolyze.

Increasing dielectric strength of cellulose ethers and esters. M. OW-ESCHINGEN. Brit. 281,663, Dec. 1, 1926. Films are soaked in oils such as paraffin oils, transformer oils or boiled linseed oil, preferably with accompanying use of vacuum and pressure.

Hydrating cellulose fiber. JUDSON A. DE CEW. Can. 282,228, Aug. 7, 1928. Cellulose fibers are hydrated in a beater of the Jordan type, by thickening the stock at an air dry concn. of over 4 parts of stock to 96 parts of H_2O and forcing it through the beater.

Fiber high in α -cellulose. GEORGE A. RICHTER (to Brown Co.). U. S. 1,678,230, July 24. See Can. 278,540 (*C. A.* 22, 2839).

Artificial silk. WILLIAM P. DREAPER. Fr. 632,609, April 11, 1927. In the spinning of artificial silk with a centrifuge box, collecting bobbins with a transverse guide are provided to which the thread is directed by hand while the box is being changed and a current of soln. is caused to descend the guide funnel to facilitate the restart of thread to the box.

Artificial silk from viscose. BRITISH DYESTUFFS CORPORATION, LTD., AND A. J. HALLWOOD. Brit. 281,117, Nov. 30, 1926. The caustic alkali customarily used in the prepn. of the viscose soln. is replaced, wholly or in part, by an org. sulfonium hydroxide such as Me_2SOH .

Artificial silk from viscose. L. LILIENFELD. Brit. 281,351, June 29, 1926. The process described in Brit. 274,521 (C. A. 22, 2273) is modified, when viscoses contg. not more than 5% of NaOH are employed, by using a coagulating bath contg. not less than 45% nor more than 55% H_2SO_4 . Various other details are given.

Artificial silk from viscose. L. LILIENFELD. Brit. 281,352, June 30, 1926. The extensibility of "viscose silk" or the like which may be produced according to the processes described in Brit. 264,161 (C. A. 22, 165), Brit. 274,521 (C. A. 22, 2273) and Brit. 274,690 (C. A. 22, 2273) is increased by treating them with a mercerizing agent such as an alkali hydroxide, alkali sulfide, H_2SO_4 , HNO_3 , H_3PO_4 , HCl, $ZnCl_2$ or a thiocyanate.

Rayon. GEORGE A. RICHTER (to Brown Co.). U. S. 1,678,354, July 24. See Can. 279,610 (C. A. 22, 2840).

Artificial thread. FREDERICK D. LEWIS (to Courtaulds, Ltd.). Can. 282,326, Aug. 7, 1928. In the manuf. of artificial threads from cellulose esters or cellulose ethers by a dry spinning process the soln. at the spinning nozzle and the air in the spinning chamber in the vicinity of the nozzle is maintained at the same temp. by subjecting the said soln. and the whole of the air in the spinning chamber to the action of the same supply of heat.

Artificial thread. CHARLES F. TOPHAM (to Courtaulds, Ltd.). Can. 282,327, Aug. 7, 1928. A soln. of cellulose acetate in acetone is projected vertically downward through a jet contg. a no. of fine holes into an atm. of warm air by a sudden considerable increase of pressure over that normally applied to produce artificial threads.

Artificial fibers and bands from viscose in acid baths. NAAMLOOZE VERNOOTSCHAP NEDERLANDSCHE KUNSTZIJDEFABRIEK. Dutch 18,030, May 15, 1928. Small addns. of Ni or Co salts (1%) to the usual sulfuric acid and sulfate spinning bath give in the product a greater affinity for dyes.

Apparatus for producing artificial silk by the stretch spinning method. ALBERT WAGNER (to Firm of Fr. Kuttner). U. S. 1,677,940, July 24.

Apparatus for maintaining uniform evaporation conditions in chambers of a plant for dry-spinning artificial silk. COURTAULDS, LTD., F. T. WOOD and E. G. TURNEY. Brit. 281,058, Oct. 11, 1926.

Pulp bleaching. CARL B. THORNE. Can. 282,025, July 24, 1928. Pulp mixed with a bleaching agent and H_2O is fed to the bleaching zone, and bleached at a d. of pulp 15 to 20%, and subsequently mixed again with the bleaching agent and H_2O and bleached at a d. of pulp of 10 to 5%. Cf. C. A. 22, 164.

Sulfite liquor. GEORGE A. RICHTER (to The Brown Co.). Can. 281,949, July 24, 1928. A composite cooking liquor for the production of high-grade sulfite pulp contains 1% combined SO_2 in the form of $Ca(HSO_3)_2$, about 1% combined SO_2 in the form of $NaHSO_3$ and about 5% free SO_2 .

Treatment of spent soda liquor. W. M. WALLACE and J. MACGREGOR. Brit. 281,035, Sept. 13, 1926. Spent soda liquors such as are obtained in the treatment of straw, grass or bamboo are calcined and discharged on a traveling furnace grate as described in Brit. 217,468 (C. A. 19, 383) and the calcined product is then passed to a dissolver, where large pieces are broken up; the soln. is led to a tank and thence to causticizing pots.

Treating "talloel." A. SCHULTZE & Co. (to Oel- und Fett-Chemie Ges.). Brit. 281,637, Dec. 4, 1926. A low absolute pressure such as 4 mm. or less is used in the sepn. of "talloel" into industrial fatty acids and resinic acids by vacuum distn., with or without steam. Fractionating columns are preferably used and the distn. is stopped when resinic acids begin to pass over. Cf. C. A. 22, 2676.

Paper. JOSEPH MCL. CATHCART. Can. 281,889, July 24, 1928. Water- and blood-proof paper is produced by introducing paper pulp into a beater, heating the pulp with live steam to 100°, adding 5% paraffin wax, and then passing the stock to a paper machine for completion in the regular manner.

Apparatus for drying paper webs, etc. J. G. OLSSON (to Aktiebolaget Svenska Flaktfabriken). Brit. 281,339, Nov. 29, 1926.

Apparatus for indicating and recording the moisture content of paper webs passing over drying rolls, etc. GEORGE S. WITHAM, JR. U. S. reissue 17,049, July 24. Original pat. 1,626,060 was issued April 26, 1927 (C. A. 21, 2063).

Suction rolls for paper-making apparatus. BELLOIT IRON WORKS. Brit. 281,590, June 24, 1926.

Removable type Fourdrinier paper machine. EARL E. BERRY (to Beloit Iron Works). U. S. 1,678,170, July 24.

Washable paper. LOUIS R. MÉCRE. Fr. 633,121, Aug. 4, 1926. See Brit. 275,617 (C. A. 22, 2274).

Waterproofing paper. J. REID (to Scutan Co.). Brit. 281,316, Nov. 26, 1926. Flexible sheets are produced by passing thin paper through a bath of bituminous material heated to about 120° or higher and removing it before it becomes completely satd. The waterproofing bath may be formed of "mineral rubber" 100, scale wax 10 and montan wax 10 parts.

Waterproofed paper. H. KUPPEL. Brit. 281,655, Dec. 2, 1926. Paper is treated with linseed oil, varnish or other waterproofing agent and is crimped to render it more resistant to tearing. It may be further reinforced by fabric, threads of jute or cotton, or by uniting one sheet of paper with another.

System of watermarking writing paper with parallel lines, etc. HENRY G. PROSSER (to Bermingham & Prosser Co.) U. S. 1,677,930, July 24.

Insulating papers. FELTEN & GUILLEAUME CARLSWERK A.-G. Fr. 633,540, Apr. 28, 1927. In making insulating papers the H_2O in the pulp is replaced by a solvent for phenolic resins, e. g., alc., and solns. contg. phenolic resins are added, and the resins are pptd. on the fiber by H_2O . Fr. 633,541 describes a process in which the resins are formed during the manuf. of the paper by adding phenols and aldehydes in the correct proportion to the pulp dild. in water.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

Explosives and their properties. I. GRAGEROFF. *Mining J.* (U. S.) 11, 134 (1928).—A discussion of the many known properties which enter into complete utilization of the potential power of explosives. E. M. SYMMES

The hygroscopic properties of smokeless powders. R. DIVIS. *Z. ges. Schiess-Sprengstoffw.* 23, 169 (1928).—The hygroscopicity of various types of smokeless powders was studied. Exact detns. are not practicable because of volatilization of residual solvent. Powders in the form of flakes with high content of nitroglycerin were the least hygroscopic. The higher the nitrocellulose content, the greater the hygroscopicity. Absorption of moisture begins at the surface and progresses toward the interior, while loss of moisture progresses in the reverse direction; hence, there is a constant shifting of moisture content with changes in temp. It has not been found possible to eliminate hygroscopicity by incorporation of nonhygroscopic materials; such changes in compn. alter the rate of change but not the degree. Ballistic stability is strongly influenced by evapn. of nitroglycerin. C. G. STORM

An example of the influence of climate on projectile velocity and gas pressure (of smokeless powder). FRANZ WENZEL AND W. PACHMANN. *Z. ges. Schiess-Sprengstoffw.* 23, 12-7 (1928).—Expts. were conducted at the Bogota munitions plant to det. the effect on the velocity and pressure, with a uniform charge of smokeless powder in 7-mm. rifle ammunition, of variations in atm. temp. and pressure such as exist in Columbia, where altitude varies from sea level to about 9000 ft. A uniformly loaded lot of ammunition was ballistically tested at 5 different locations where barometric pressure varied from 546 mm. to 721 mm. and temp. from 14° to 30°. Correction being made for the influence of atm. pressure, a change of 1° in temp. causes a change of 0.9 in velocity and 11.4 atm. in chamber pressure. Increased uniformity in ballistics and a saving of powder can be obtained by a proper adjustment of charge for each climatic zone in which the ammunition is to be used. The tests are described in detail and results of all firings tabulated. C. G. STORM

Dinitrobenzene as a substitute war explosive. BELOV. *Vojensko-Technické Zprávy*, No. 2 (1928); *Z. ges. Schiess-Sprengstoffw.* 23, 170 (1928).—Although not suitable for use alone as a military explosive, dinitrobenzene in mixt. with TNT is equiv. to TNT in explosive effect, and such mixts. were largely used by Germany during the World War. The manuf. of DNB is described. C. G. STORM

The use of thermite for the blasting of ice jams. J. SOUHRADA. *Vojensko-Technické Zprávy*, No. 2 (1928); *Z. ges. Schiess-Sprengstoffw.* 23, 170 (1928).—An account of unsuccessful attempts to break an ice jam on the Danube in Jan., 1928. Three charges from 20 to 62.1 kg. of thermite were used without result. Seven hrs. later the jam broke 500 m. up-stream following a river rise of 1.62 m. (cf. *J. Franklin Inst.* 203, 611-34). C. G. STORM

The action of the thermite reaction in breaking up ice jams. N. HAMPL. *Vojensko-Technické Zprávy* No. 2 (1928); *Z. ges. Schiess-Sprengstoffw.* 23, 170 (1928).—The theory of Barnes (*J. Franklin Inst.* 203, 611-34), that the effect of thermite on ice jams

is largely due to the release of heat energy, is disputed. H. believes the main component to be the wave motion set up by the reaction, and specifies optimum form of container for the charge and its proper location in the ice. C. G. STORM

The Abel test. A. KOEHLER AND M. MARQUEVROL. *Mem. poudres* 23, 11-8 (1928).—From tests on a number of lots of pyroxylin and guncotton all of which contained small amts. of CaCO_3 , it is indicated that the latter reacts with the nitrocellulose to form Ca nitrite which decomposes to NO. Therefore the higher the percentage of moisture in the nitrocellulose before drying, the greater the decompn. and the lower the stability. During the first period of drying the nitrite is formed and during the last period of drying it is decompd. Decarbonated powders are unaffected while moist powders contg. CaCO_3 stored at ordinary temps. give a lower stability test with time. Drying in a vacuum does not decompose the nitrite and it may be removed by washing with pure cold water. It is concluded that the Abel test is worthless for measuring the stability of powders and it is recommended that (a) it be replaced by the Bergmann-Junk test or the coeff. of exchange (C. A. 22, 2275); (b) that it be used as a control for the elimination of nitrite formed during manuf.; (c) that specimens be washed with cold distd. water dried in a vacuum and tested at 77° or higher and (d) that specimens be decarbonated and the moisture content adjusted to 30% before drying. [The conclusion applies to powders purified with hard water or where CaCO_3 is added during beating.—ABSTR.] A. J. PHILLIPS

The fusibility of mixtures of picric acid and nitronaphthalene. M. JOVINET. *Mem. poudres* 23, 36-42 (1928).—A eutectic melting at 49.8° is formed from a 16-84 mixt. of picric acid and nitronaphthalene. Cooling and melting curves as well as phys. appearance showed the presence of a combination of 1 mol. of picric acid with 1 mol. of nitronaphthalene (57-43), which melts and dissociates at 71°. A. J. PHILLIPS

Estimation of camphor in powder. J. DESMAROUX. *Mem. poudres* 23, 43-53 (1928).—A method based on the measurement of the surface tension of aq. solns. of camphor. A quantity of powder corresponding to 0.15-0.2 g. of camphor is saponified and decompd. by NaOH or KOH and distd. into a long-necked flask with a mark at the 300-cc. level. About 150 cc. of distillate is collected in the flask, which is surrounded by a mixt. of ice and water and the wet pasty camphor is brought into soln. by filling to the mark with water and shaking vigorously. The surface tension is measured by the wt. of a falling drop from a capillary tube which forms a drop in 10-12 secs. The tip of the capillary is cone-shaped and the end is polished optically flat. The app. was calibrated with refined natural camphor, artificial camphor and fenchone. It was found that the variation in wt. of the drops was not a linear function of the concn., the results being represented by a parabolic curve. From a mathematical discussion of the errors involved it is concluded that accurate results are obtained within the above-mentioned concns. of camphor. The presence of nitroglycerin and of diphenylamine in the powder had no effects on the results, but the soly. of the substituted ureas and their effect on surface tension prevent the method being used on powders in which they are present. A. J. PHILLIPS

The fixation of camphor by nitrocellulose. J. DESMAROUX. *Mem. poudres* 23, 54-62 (1928).—Absorption curves made by measuring the refractive indices of solns. of camphor in a satd. hydrocarbon, in contact with nitrocellulose, showed the curves to be analogous to those given by the substituted ureas (cf. C. A. 17, 3606). Camphor is not absorbed below a crit. concn. and above it the nitrocellulose is satd. with camphor. There is a discontinuity in absorption corresponding to a crit. concn. A more direct method for measuring the absorption was found by dissolving nitrocellulose in ether-alc. with varying concns. of camphor, prep. thin films on glass of the gelatinized material, heating $40 \times 40 \times 0.15$ mm. squares of the film in an oven at 50° and measuring the loss in wt. as well as the rate of loss. The latter was plotted against the concn. of camphor. Above a certain concn. the rate increases sharply. This indicates the formation of a complex between nitrocellulose and camphor. It was found that the concn. limit increased with the N content of the nitrocellulose. The presence of nitroglycerin increased the rate of volatilization of the camphor, so that the two cannot be used in the same powder. A. J. PHILLIPS

Determination of alcohol, ether and water in the solvent eliminated from powder during drying. L. A. CHENAL. *Mem. poudres* 23, 4-6 (1928).—Absorption in an atm. of N is used in order to prevent the oxidation of alc. absorbed by KOH. N is generated by the action of Cu turnings on NH_4OH , purified and conducted to the absorption app. This consists of a bulb filled with pumice stone and H_2SO_4 of known vapor pressure, so that either wet or dry N may be employed, a tube contg. the powder to be tested, a K_2CO_3 tube to absorb H_2O , a KOH tube to absorb EtOH , a U tube with pumice-

H₂SO₄ for Et₂O and a H₂SO₄ safety tube. One l. of N is passed through the powder at a known temp. and then by means of a 3-way stopcock and a side tube, a 2nd l. is passed through the saturator, by-passed around the powder tube and passed through the remaining tubes in order to clean them out. A. J. PHILLIPS

Decomposition products of amyl alcohol in poudre B. M. MARQUEYROL. *Mem. poudres* 23, 7-10(1928).—Characteristic qual. tests on Poudre B of varied compn. which has been heated at 75° for 140-170 hrs. and then exposed to air for 11 yrs. indicated that the normal decompn. of nitrocellulose in the presence of amyl alc. gives rise to the formation of amyl nitrite. This further decomposes to valeric acid, amyl valerate and amyl nitrate. A. J. PHILLIPS

Distribution of diphenyl in poudre B. J. DESMAROUX. *Mem. poudres* 23, 33-5 (1928).—Analysis of material scraped from the surface and interior of both green and dried grains showed that there is a greater concn. of diphenylamine at the surface than at the center of the grain, that it takes place before solvent recovery is completed and that it is caused by the deposition of diphenylamine from the solvent which is diffusing from the center to the surface and evapng. A. J. PHILLIPS

Determination of organic matter in mixed acid and of carbon in nitrocellulose (CARRIERE, GUIBERT) 7. Determination of nitrite in nitrocellulose (KOEHLER, MARQUEYROL) 7. The uneven nitration of nitrocellulose (BENEDICT) 26. Nitration process in general and nitration of glycerol (MASHKIN) 10. Metallic complexes of cellulose nitrate (APARD) 23.

NAOUM, PHOKION: **Nitroglycerine and Nitroglycerine Explosives.** Translated by E. M. Symmes. Vol. I of the World Wide Chemical Series. Baltimore, Md.: The Williams & Wilkins Co. 470 pp. \$7. Reviewed in *Chemicals* 30, No. 7, 8(1928).

Safety device for protecting oil-storage reservoirs from lightning. GEORGE L. TICEHURST. U. S. 1,678,539, July 24.

Safety device for drawing oil from tanks when ignited. HENRY T. SCOTT and LUCIEN E. RONE. U. S. 1,678,605, July 24. A fusible device is connected to a lever which operates a draw-off valve.

Electric fuses. W. ESCHBACH and W. FRIEDRICH. *Brit.* 281,239, Nov. 23, 1926. Igniting pellets for elec. fuses are made of material having such a short period of combustion that dynamite and fire damp will not be exploded by the material, e. g. di and tri-nitrophenols.

Protector (of a soft rubber composition) for blasting fuses. GEORGE A. LIVERMORE (to B. F. Goodrich Co.). U. S. 1,678,257, July 24.

Storing inflammable liquids or gases under pressure. SOC. L'ACÉTYL. *Fr.* 633,637, Apr. 30, 1927. Peat used in storing liquids or gases, especially dissolved acetylene, has a degree of humidity between 2 and 19% so that it does not become dusty and is not too porous to risk danger in case of explosion, and the spaces between the grains are sufficiently small to prevent an explosion centering in these spaces

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Action of ultra-violet rays upon cotton dyes. EMILIO CRISPI. *Atti congresso nat. chim. pura applicata* 2, 833-5(1926).—Many of the hypotheses regarding the nature of light and its action are insecurely founded. There is no absolute parallelism between the action of solar radiation and ultra-violet radiation. Apparently the bleaching action of ultra-violet rays is due solely to their physico-chem. nature and not to ozone formation. L. T. F.

Beam dyeing. F. H. MCCOY. *Proc. Am. Assoc. Textile Chem. Colorists* 1928, 202-3; *Am. Dyestuff Rept.* 17, 474-5. L. W. RIGGS

Dyeing cotton with alizarin dyestuffs. A JACKSON. *Dyer, Calico Printer* 59, 226-7, 252-3; 60, 16-7, 29(1928).—Practical procedures, including formulas, are given. RUBY K. WORNER

Treating and dyeing ramie. FRED GROVE-PALMER. *Dyer, Calico Printer* 59, 248-50(1928).—The cultivation of ramie in different countries, its processing and its use for textile fabrics are briefly considered. RUBY K. WORNER

The dyeing of sisal hemp. FRED GROVE-PALMER. *Dyer, Calico Printer* 60, 53 (1928); cf. C. A. 22, 2276.—A brief discussion of the cultivation and uses of sisal hemp and a description of the general procedures for dyeing it with basic, direct or acid dyes are given.

Dyeing of natural silk. A. THOMSON. *J. Soc. Dyers Colorists* 44, 202-4 (1928).—Choice of dyes and methods of application to the fiber are discussed. L. W. RIGGS

Dyeing of acetate silk and of mixed fabrics. G. RUDOLPH. *Kunstseide* 10, 53-5 (1928).—A discussion of the use of the dyes manufd. by the I. G. Farbenind. A. G., Cellit fast dyes, Celliton and Celliton fast dyes and Cellitazoles. F. O. H.

Rayon dyeing and later processes. ANON. *Textile World* 74, 187-9 (1928).—Suggestions are given for the practical dyer. RUBY K. WORNER

Dyeing and waterproofing of viscose rayon. G. RUDOLPH. *Kunstseide* 10, 13-4 (1928).—Details are given for methods of dyeing rayon with Sirius colors. A procedure is given also for waterproofing rayon fabrics using Ramasit W. D., a recent product of the I. G. Farbenind. A. G. that is rich in paraffin. F. C. H.

Dyeing lenos and nets. D. WILLIAMS. *Dyer Calico Printer* 59, 251 (1928).—Practical methods, with formulas, are given. RUBY K. WORNER

Union dyeing from a garment dyer's point of view. A. J. CROCKATT. *J. Soc. Dyers Colorists* 44, 197-201 (1928).—This subject involves the handling of an endless variety of conditions and combinations of fibers, cloth, stains, faded materials and dyes. Procedures for many particular cases are given. L. W. RIGGS

Fastness: The silk dyer's problem. RAYMOND CURTIS. *Proc. Am. Assocn. Textile Chem. Colorists* 1928, 205-8; *Am. Dyestuff Rept.* 17, 477-80. L. W. R.

Printing mixture cloths of cotton or viscose and celanese. W. BENNETT. *Dyer, Calico Printer* 59, 204-5, 230 (1928); cf. C. A. 22, 872.—Practical directions are given for printing solid, bi-color and multi-color effects on mixed fabrics of cotton or viscose and cellulose acetate. RUBY K. WORNER

Dyeworks alums from wastes. E. T. ELLIS. *Dyer, Calico Printer* 59, 212-3, 236-7 (1928).—Methods of prepn. are described. RUBY K. WORNER

Starch-converting enzymes used in the textile industries. ROBERT P. WALTON. *Am. Dyestuff Rept.* 17, 461-2 (1928).—The various trade diastases are classified according to origin as malt, pancreatic, fungus and bacterial. The fatal temps. for the first 3 are 80°, 55° and 82°, resp. Optimum temps. range from 10° to 25° lower than fatal temps. The optimum p_H for malt diastase ranges from 4.0 to 5.0, for pancreatic diastase about 7.0, fungus diastase 5.4, while bacterial diastases are effective in both acid and alk. solns. The presence of salts has an activating and stabilizing effect on the diastases. L. W. RIGGS

Structure of natural silk. P. P. V. VEIMARN. *Kolloid-Z.* 45, 162-4 (1928).—From an ultramicroscopic study of the phenomena following the fiber cleavage in the swelling and dispersion of silk fiber in salt solns., V. states that the silk fiber becomes divided into small fibrils whose dimensions are never over 200 μ , that is, they are of colloidal dimension. This study also confirms V.'s theory that the vectorial field of the dispersed particles of fibroin possess especially strong cohesion at both ends. FREDERICK C. HAHN

Acetate rayon in fabrics made from mixed filaments. JAR. FRANĚK. *Chem. obzor* 3, 12-5 (1928).—After a short historical sketch and description of characteristics of acetate rayon (I) some newer methods of dyeing are proposed. The dyeing of I differs widely from the dyeing of other sorts of rayon and for this reason a combination of 2 or 3 different fibers (cotton, viscose and I, wool and I, silk and I, cotton, silk and I and finally semiwool (wool with cotton) and I) causes the production of two-color effects. By using certain dyes one color can be obtained. JAR. KUČERA

Some possible applications of p_H control in the cotton industry. CHARLES E. MULLIN. *Proc. Am. Assocn. Textile Chem. Colorists* 1928, 197-200; *Am. Dyestuff Rept.* 17, 469-72.—An address. L. W. RIGGS

The relation between the structure of organic fibers and their elastic qualities. R. O. HERZOG. *Naturwissenschaften* 16, 420-1 (1928).—The size of the fibrils in various vegetable or animal fibers is about 0.2 to 0.4 μ ; these are considered to be formed by directional coagulation from the fiber-forming sol, the primary unit being crystallites of the dimension 100 A. U. From an equation of Becker, $D\eta = \alpha/8\phi\delta^2$, where D is the coeff. of internal diffusion, η viscosity of gel, α material const., ϕ torsion modulus, δ diam. of colloidal particles in gel, indications as to which unit det. the elastic properties may be derived. By using a δ of about 10^{-6} cm. (crystallite), $\phi = 10^{10}$ dynes per sq. cm. (empirical values are given for 10 fibers), α is found to be of the order 10^{-4} . B. J. C. VAN DER HOEVEN

Dyes. BRITISH DYE STUFFS CORP., LTD., and MORDECAI MENDOZA. Fr. 632,497, Apr. 8, 1927. New pyrazolones are produced when the hydrazines obtained by reducing diazo compds of the amino derivs of 3-carboxy-4-hydroxydiphenyl sulfide described in Brit. 260,058 (C. A. 21, 3468) are condensed with β -ketonic esters; thus the hydrazine from 2'-amino-3-carboxy-4'-hydroxy-4'-sulfodiphenyl sulfide is condensed with acetoacetic ester and oxalacetic ester to yield the corresponding 3-methyl- and 3-carboxypyrazolones. Azo dyes are obtained by coupling the above pyrazolones with diazo compds; thus, the 3-methylpyrazolone from 2'-amino-3-carboxy-4'-oxy-4'-sulfodiphenyl sulfide is coupled with diazotized sulfanilic acid, 2,5-dichlorosulfanilic acid, naphthionic acid, aminoazobenzene and benzeneazo-1-naphthylamine-6(or 7)-sulfonic acid and with tetra-azotized benzidine, and (2) the corresponding carboxypyrazolone is coupled with diazotized sulfanilic acid, 2,5-dichlorosulfanilic acid and naphthionic acid.

Dyes. C. M. BARNARD and BRITISH ALIZARINE CO., LTD. Brit. 281,114, Jan. 6, 1927. Dyes suitable for use on cellulose acetate or other cellulose esters are formed either by fusing citric acid with *p*-aminobenzeneazo- β -naphthol or other suitable azo dye contg. one or more free primary amino groups but no sulfonic group or by fusing an aromatic compd. such as *p*-nitroaniline with citric acid and then converting the product into an azo dye. Yellow and orange-brown shades are produced.

Dyes. BRITISH ALIZARINE CO., LTD., W. H. DAWSON and P. BECHIN. Brit. 281,016, Aug. 26, 1926. Non-dyeing by products obtained in the prepn of violanthrone and isoviolanthrone by alk. condensation of benzanthrone or Bz-1-halobenzantrones are converted into dyes by a further treatment with alkali at high temp.

Dyes. BRITISH DYE STUFFS CORP., LTD., JAMES BADDILEY, PERCY CHORLEY and RAINALD BRIGHTMAN. Fr. 632,740, Apr. 13, 1927. Silk fabric of regenerated cellulose, such as viscose, is dyed by the dyes obtained by combining in acid or alk. soln. 2-amino-8-naphtholsulfonic acid or their *N*-substituted derivs with diazo or tetrazo compds. Examples and the colors obtained are given.

Dyes. BRITISH DYE STUFFS CORP., LTD., and SIDNEY THORNLEY. Fr. 633,089, Apr. 22, 1927. The vat dyes prepd. by the alkali fusion of benzanthrone-sulfonic acids are treated with hydroxylamine or one of its salts to give new black or gray vat dyes. The vat dyes described in Fr. 632,671 (cf. following abstract) are so treated. According to Fr. 633,090 new vat dyes are prepd. by alkylation instead of treatment with NH_2OH . The dyes may be oxidized, or oxidized and reduced before alkylation.

Benzanthrone derivatives. BRITISH DYE STUFFS CORP., LTD., JAMES BADDILEY, ARNOLD SHEPHERDSON and SIDNEY THORNLEY. Fr. 632,671, Apr. 12, 1927. Benzanthrone is sulfonated by means of concd. H_2SO_4 or fuming H_2SO_4 with or without catalysts such as Hg. On fusing with alkalis vat dyes are obtained which readily form leuco compds. They also form starting points for new dyes. Examples are given of the sulfonation of benzanthrone and methylbenzanthrone. Cf. C. A. 22, 2470.

Dyes. I. G. FARBENIND., A.-G. Brit. 280,886, Nov. 18, 1926. Vat dyes are made by action of alk. reagents on benzanthrone-1-aminoanthraquinones alkylated at the N atom, *e. g.* *N*-methyl-Bz-1-benzanthronyl-1-aminoanthraquinone may be

heated at 98° with alc. KOH to form a product dyeing cotton in blue-green shades from the vat. *N*-methylbenzanthranyl-1-aminoanthraquinones are made by alkylating benzanthranyl-1-aminoanthraquinones or by condensing halobenzanthrones with 1-alkylaminoanthraquinones.

Dyes. I. G. FARBENIND. A.-G. Fr. 632,490, April 8, 1927. New coloring matters of the anthraquinone series are produced by introducing into the anthraquinone mol. hydroaromatic amine radicals or amino cyclic paraffins, such as hexahydroaniline or hexahydrotoluidine, *o*-aminocyclohexanol, pentamethylenamine and bornylamine. The compds. color wool blue to bluish green shades fast to light. An example is given of the prepn. of 1-amino-4-hexahydroanilinoanthraquinone-2-sulfonic acid from 1-amino-4-bromoanthraquinone-2-sulfonic acid and hexahydroaniline.

Dyes. I. G. FARBENIND. A.-G. Fr. 632,637, April 11, 1927. An alkylcellulose is added to insol. or slightly sol. dyes to preserve them in a fine state of division.

Dyes. I. G. FARBENIND. A.-G. Fr. 632,887, April 15, 1927. Artificial silk made from cellulose esters and ethers is dyed by means of monoazo dyes produced by coupling a diazo compd. of the benzene or naphthalene series contg. at the most one sulfo group, with a phenol substituted in the *p*-position.

Dyes. I. G. FARBENIND. A.-G. Fr. 633,109, June 25, 1926. Sol. dyes contg. at least 2 nitro groups in the mol. are prepd. by reaction of aromatic nitro compds. contg. an exchangeable halogen, except 1-halo-2,4-dinitrobenzene, with a mol. of 4-amino-diphenylamine or its derivs. or substitution products. Examples are given, all of which contain sulfonic groups. The products dye wool and leather.

Dyes. FABRIQUE DE PROD. CHIM. ROHNER SOC. ANON. PRATTELN. Fr. 632,577, Aug. 2, 1926. See Brit. 275,147 (*C. A.* 22, 2278).

Dyes. L. B. HOLLIDAY AND CO., LIMITED, and CECIL SHAW. Fr. 633,292, April 25, 1927. Black vat dyes which dye cotton violet and greenish blacks are prepd. by treating dibenzanthrone with energetic oxidizing agents, such as a dichromate, permanganate or chlorate in H₂SO₄. They probably contain 6 atoms more of O than dibenzanthrone as compared with the already known oxidation products contg. 4 atoms more of O than dibenzanthrone. Cf. *C. A.* 22, 2470.

Dyes. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Fr. 633,473, April 27, 1927. Sulfur dyes are prepd. by the sulfuration of the leuco derivs. of indophenols obtained by condensation of nitrosophenols with carbazole, or its *N*-substituted alkyl derivs. or a mixt. of carbazole with these derivs. in the presence of an aliphatic N compd. such as urea, dicyanodiamide, semicarbazide, guanidine or its salts, thiourea, NH₄CNS, acetamide or malonamide. Examples are given.

Dyes. A. ZINKE (to F. Bensa). Brit. 281,281, Nov. 26, 1926. Chloroperylene quinones are made by treating highly chlorinated perylenes with fuming sulfuric acid at a temp. of 130-180°. Dodecachloroperylene yields a dye giving a red color on cotton from the vat, which changes to olive-green on exposure to the air and to red or violet on treatment with metal salts such as those of Fe and Cr. Highly chlorinated perylenes are made by passing dry Cl into a soln. or suspension of perylene or a low-chlorinated perylene in an inert solvent such as PhNO₂ contg. chloride of Al or of Sb. Cf. *C. A.* 22, 2668.

Dyes; photographic developers. I. G. FARBENINDUSTRIE AKTIENGESSELLSCHAFT. Fr. 632,273, Apr. 6, 1927. Aromatic *p*-diamines used for coloring dead and living hair and as photographic developers are made stable to air by treating them in the absence of H₂O in an indifferent solvent with SO₂.

Azo dyes from 2,3-hydroxynaphthoic acid arylides. LEOPOLD LASKA and ARTHUR ZITSCHER (to Grasselli Dyestuff Corp.). U. S. 1,678,599, July 24. Dyes producing various red shades are formed by the combination of diazo compds. of 2-aminotoluene-4-sulfodimethylamide, 2-amino-1-ethoxyphenyl-4'-sulfodimethylamide or 2-aminotoluene-4-sulfo-*N*-methylaniline with 2,3-hydroxynaphthoic acid arylides such as those of 4-chloro-2-anisidine, 2 phenetidine, α - or β -naphthylamine, 3-toluidine, 4-chloroaniline, 5-chloro-2-toluidine or 5-chloro-2-anisidine. The dyes may be produced as such or on the fiber or a substratum and give dyeings fast to kier boiling.

Copper compounds of substantive azo dyestuffs. I. G. FARBENIND. A.-G. Fr. 632,941, Apr. 16, 1927. Cu compds. of substantive azo dyestuffs are prepd. by treating with a compd. yielding Cu dyestuffs produced from diazo or diazoazo compds. of such monoamines or their derivs. as contain in the *o*-position to the amino group at least one unsubstituted or substituted alkyloxy, aralkyloxy or aryloxy group. Colors of the most varied shades are obtained, very fast to light, alkali and ironing. The invention is widely applicable and several examples are given.

Indigo. CHARLES J. STROSACKER and CHESTER C. KENNEDY (to Dow Chemical

Co.). U. S. 1,678,619, July 24. A phenyl compd. and an alkali, such as phenylglycine and caustic alkalies, are placed in a container, and heated in a bath of caustic alkali or other suitable molten material of about the same m. p. as that of the alkali; the container is finally removed from the heating agent and, without material access of air, is submerged in water.

Indigoid dyes for cellulose esters. C. M. BARNARD and BRITISH ALIZARINE CO., LTD. Brit. 281,213, Jan. 6, 1927. Citric acid is fused with unsulfonated indigo or thioindigo dyes contg. one or more free primary amino groups; *e. g.*, 7,7'-diamino-thioindigo yields a product dyeing cellulose acetate violet-red.

Indanthrone and its disulfonic acids. BRITISH DYESTUFFS CORP., LTD., ARNOLD SHEPHERDSON and ANTHONY J. HAILWOOD. Fr. 632,331, Apr. 7, 1927. 1-Nitroanthraquinone-8-sulfonic acid is reduced with less reducing agent than is necessary for reduction to the amino compd. The product, probably 1-hydroxylaminoanthraquinone-8-sulfonic acid, yields indanthronedisulfonic acid on heating with alkali. The sulfonic groups can be split off by electrolytic reduction. The disulfonic acid dyes cotton from the vat in fugitive shades and wool from an acid bath.

Ketones of the anthracene series. I. G. FARBENIND. A.-G. Fr. 633,071, April 22, 1927. *meso*-Anthracyl alkyl ketones are prepd. by the action of aliphatic acid chlorides on anthracene or its homologs or derivs. with condensing agents under moderate conditions. Under more energetic conditions α - or β -anthracyl alkyl ketones are produced. Oxidation gives the corresponding anthraquinone derivs. The compds are starting materials for dyes.

Sulfur black. RAYMOND VIDAL. Fr. 633,395, Aug. 14, 1926. Sulfur black liquids are prepd. directly by the use of nitroso-*o*- (or *m*)-cresols alone or with dinitrophenol and picric acid.

Lakes. I. G. FARBENIND. A.-G. Fr. 633,028, April 21, 1927. See Brit. 270,750 (C. A. 22, 1692).

Dyeing. I. G. FARBENIND. A.-G. Fr. 633,363, April 26, 1927. An app. is described for dyeing textiles difficult to dye, in which the textiles float freely in the bath and are stirred by alternate suction and compression. In the case of vat dyes the temp. is carried to 80-90° and an aldehyde or ketone is added.

Dyeing. I. G. FARBENIND. A.-G. Fr. 633,505, April 27, 1927. Aldehydes or ketones, particularly those of low mol. wt., are added to the dye bath, to enable the dyeing to be carried out near the b. p.

Dyeing. J. I. M. JONES, W. KILBY and STANDFAST DYERS & PRINTERS, LTD. Brit. 280,983, June 28, 1926. Sol ester derivs. of leuco vat dyes are applied by padding to textile materials, which are then steamed without drying and the shade of the dye is then developed in a suitable bath. Oxidizing agents may be added to the padding bath if of such character as to be relatively inactive during steaming or acid oxidizing agents may be used in the developing bath. Examples are given.

Dyeing and printing. DURAND ET HUGUENIN SOC. ANON. Brit. 281,336, Nov. 29, 1926. In dyeing or printing textile materials with ester salts of leuco vat dyes (such as those of Brit. 186,057; C. A. 17, 343) as described in Brit. 220,964 (C. A. 19, 1058), with development by steaming, there is added to the padding bath or printing paste contg. the ester salt and oxidizing agents a substance which yields acid when heated but which does not form an insol. salt with the ester salt. Among the substances which may be used are: mono- or di-chlorohydrin, chlorethyl alc., diethyl tartrate and K, Me or Et sulfate.

Dyeing with vat and azo dyes. WILHELM WINTERHALDER (to Grasselli Dyestuff Corp.). U. S. 1,678,580, July 24. In dyeing cotton, artificial silk and silk with vat and azo dyes, the goods are grounded with an azo component and at the same time with a vat dye dissolved without esterification, and the vat dye is converted into insol. form by oxidation and the ice color developed on the fiber by a diazo soln.

Dyeing mixed textile fabrics. HERMANN WAGNER, HEINZ EICHWEDE and ERICH FISCHER (to Grasselli Dyestuff Corp.). U. S. 1,678,611, July 24. Goods comprising mixed wool and silk are dyed with a pyrazolone-azo dye contg. at least one carboxylic acid ester group in the dye mol. and contg. no free COOH group linked to the C in the 3-position of the pyrazolone ring; *e. g.*, the dye from *o*-chloroaniline and 1-(4'-sulfo-phenyl)-5-pyrazolone-3-carboxylic ethyl ester.

Dyeing "viscose silk" or similar regenerated cellulose materials. BRITISH DYESTUFFS CORPORATION, LTD., J. BADDILEY, P. CHORLEY and R. BRIGHTMAN. Brit. 281,410, Sept. 7, 1926. Level shades are obtained by the use of dyes formed by coupling diazotized aromatic amines and their derivs., such as sulfonic or carboxylic acids, with 2-amino-8-naphtholsulfonic acids or their N-substituted derivs. (other than those

described in Brit. 270,446 (C. A. 22, 1691) and Brit. 270,883 (C. A. 22, 1693). Numerous examples are given.

Dyeing furs and leather. V. ZETTLITZ and A. PFERFER. Brit. 281,592, Nov. 30, 1926. See U. S. 1,649,502 (C. A. 22, 509).

Apparatus for washing or dyeing artificial silk threads, etc. JULIUS BRENZINGER (to Max Ams Chemical Engineering Corp.). U. S. 1,678,053, July 24.

Dye-baths. MARIUS RATIGNIER. Fr. 632,252, July 17, 1926. To ensure the normal immersion of the fabric in a dye-bath the tray or screen carrying the cloth is connected by belts to a crankshaft, raising of which tips up the tray and plunges the fabric into the bath.

Copying colors. I. G. FARBENIND. A.-G. Fr. 633,311, April 25, 1927. Copying colors suitable for copying pencils are prepd. from black azo dyes obtained by diazotizing phenosafranine and coupling it with a cresol. Thus the black dye prepd. from diethylphenosafranine and *p*-cresol, and the black dyes prepd. by coupling diazotized phenosafranine with a *p*-cresol contg. an alkyl or aralkyl group in the *m*-position to the OH group, *e. g.*, 4-methyl-3-monoethyl(or benzyl)amino-1-phenol, are particularly suitable.

Producing color effects on threads. CAMILLE DREYFUS. Fr. 632,339, April 7, 1927. Cops or bobbins of thread, *e. g.*, cellulose acetate silk, are plunged into a bath contg. several colors having different powers of penetration and drawing them out before they become uniformly colored.

Mercerizing cotton and similar materials. BRITISH DYESTUFFS CORPORATION, LTD. and A. J. HALLWOOD. Brit. 281,473, Nov. 30, 1926. An alkyl-substituted sulfonium hydroxide such as Me_2SOH is used instead of part or all of the caustic alkali usually employed in mercerizing or similar processes. Cotton fiber thus treated is improved as to strength and affinity for dyes.

Treating fabrics containing cellulose esters or ethers. BRITISH CELANESE, LTD., and G. H. ELLIS. Brit. 280,989, July 27, 1926. The material is rendered resistant to "laddering" by treatment with a soln. or dispersion contg. 8% or more of substances such as oleic, stearic or palmitic acids and sulfonated derivs. such as sulforicinoleic acid or their salts such as the alkali metal or ammonium salts, sulfoaromatic fatty acids such as sulfophenylstearic acid, hydroxysulfophenylstearic acid and sulfonaphthylricinoleic acid or their mixts. or salts, or sol. resin soaps. The treatment may be effected at 80–100°. Brit. 280,990, for the same purpose, specifies the use of solns. or dispersions contg. at least 5% of various hydrocarbons such as those of the paraffin, aromatic, naphthene or terpene series, their hydrogenated or halogenated derivs., various alcs., phenols, ketones or carbocyclic sulfonic or carboxylic acids. A large number of examples are given.

Stockings from fabric containing cellulose acetate or like material. C. DREYFUS (to British Celanese, Ltd.). Brit. 281,271, Nov. 26, 1926. Knitted fabrics contg. cellulose esters such as cellulose acetate are cut or stamped with a hot tool which serves to fuse or melt the threads together and prevent "laddering."

Nacreous threads. DESPOMMIERS ET PAQUIER. Fr. 632,107, July 13, 1926. The brilliant compd. extd. from fishes or animal products and known as "Essence d'Orient" is added to threads, particularly artificial silk, during their manuf.

Method and apparatus for cleaning and separating hair. EINAR J. OLSEN (one-half to Sealy Mattress Co. of Minn.). U. S. 1,678,525, July 24. Mech. features.

Compositions for treating animal hair or wool for making hats, etc. E. BÖHM. Brit. 281,646, Dec. 1, 1926. Nascent Cl is generated in contact with the material, *e. g.*, by use of NaCl , H_2O_2 and H_2SO_4 in dil. soln., in order to increase the luster of the material. Org. substances such as aniline-HCl may be used also for evolving Cl, and the treatment may be applied to material either before or after making up into hat bodies.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Progress in painting materials. H. VOLLMAN. *Farbe u. Lack* 1928, 222–3, 226–7.—The vast majority of coating materials are colloidal and the drying process passes through the stages: colloidal soln., highly solvated gel, weakly solvated gel film. Desolvation of the film progresses with age with consequent increase in hardness. The addn. of pigments decreases water permeability by lengthening the path the water mols. must

travel and perhaps by reaction with oils to form a denser film. Deterioration often starts at points of insufficient mixing of pigment and vehicle. G. G. SWARD

Paints for the graphic industry. LEO ARNSTEIN. *Chem. abstr.* 3, 34-6(1928).—A review on mineral pigments, new combinations of earth paints (cadmium yellow, titanium white), color lakes (pptd. by tungstomolybdic and phosphotungstic acids), soots and problems of the manuf. of varnishes confronting the chemist. J. K.

Paints, pigments, varnishes and resins, 1927. Reprint from *Reports of the Progress of Applied Chemistry* 12, 346-97(1927).—For Oil, Colour Chem. Assoc. 1928. This pamphlet briefly abstracts and gives a reference list of the work published during 1927. R. J. MOORE

Standardizing dry testing of colors. II. ALBERT GRUNDER AND R. S. SHEPHERD. *Paint, Oil, Chem. Rev.* 86, No. 6, 8-11, 25(1928); cf. *C. A.* 22, 2672.—Some of the tests now commonly used for pigments are criticized and certain variations or substitutions are suggested. The tests discussed are strength, opacity, oil absorption, permanence to light, bleeding and chem. identification tests. The strength testing of yellows by rubbing up with blue instead of white is approved. Analysis is shown to be of little value in detg. color strength of a lake. The Gardner-Colman oil absorption method is criticized as is also the method of measuring the vertical flow on glass of 5 drops of the thin pigment in oil. Artificial light tests for accelerating color changes in pigments are shown to be inconsistent. They are applicable when making comparative tests on colors of the same basic type. Various methods of making bleeding tests are offered. Identification tests are discussed and a table of H₂SO₄ spot tests is given to distinguish between various organic reds. R. J. MOORE

Color standardization and testing in the paint and color industry. C. A. KLEIN, et al. *J. Oil Colour Chem. Assocn.* 10, 309-34(1927).—A discussion of color problems from a no. of different viewpoints. The need for quant. terms and more exact comparisons is stressed. Various methods for pigment standardization and color measurement are described. R. J. MOORE

Colloid chemistry of paints, varnishes and their components. R. S. MORRELL AND W. E. WORNUM. *J. Oil Colour Chem. Assocn.* 11, No. 92, 49-62, No. 93, 90-112(1928).—A review which stresses the colloidal aspects of paints and varnishes under the following headings: yield value and mobility; wetting and grinding; pigments; drying oils with respect to emulsions, surface tension, polymerization and oxidation; resins; varnishes. A reference list to these subjects is given. R. J. MOORE

Some methods of testing the suitability of paints, varnishes, and lacquers for aeronautical purposes. E. W. J. MARDLES. *J. Oil Colour Chem. Assocn.* 11, 230-59(1928).—The exptl. results relate to protective coatings for metal and wood parts and not to the tightening action on fabric. The paper is divided into 4 sections as follows: (1) *Influence of wt. of film on protection afforded*—Data are tabulated for exposure and sea water spray and immersion tests on Al alloy, mild steel and silver spruce. (2) *Mech. properties of the film*.—These were detd. by a scratch-hardness test, bending test and an abrasion or erosion test, all of which are described and the results discussed. In the erosion test silver sand, 30-60 mesh, was blown by compressed air (5 lb. per sq. in.) against a panel held at a distance of 12 in. Hard tough films such as obtained from certain cellulose lacquers were found to be less resistant to sand erosion than softer oil varnish films. Apparently, the more resilient or rubber like a film was, the greater was its resistance. (3) *Resistance of protective coatings to water, oil and gasoline, dope solvents, etc.* (4) *Methods for the detn. of drying time, viscosity and gloss*.—A panel is defined as hard dry when upon pressure with the coated surface in contact with a bed of sand, using a load of 100 g. per sq. cm., it can be freed from all sand particles with a camel's hair brush without injuring the film. A discussion follows. R. J. M.

Laboratory apparatus for preparing duplicate uniform paint, varnish, and lacquer films. J. C. BRIER AND A. M. WAGNER. Univ. of Mich. *Ind. Eng. Chem.* 20, 759-64(1928).—A mechanical app. has been devised with a doctor blade having a micrometer adjustment, by means of which a uniform thickness of film can be secured. The fluid sample is contained in a tight basket, which prevents loss of volatile matter and permits weighing of the film. T. S. CARSWELL

Antique colors and color manufacture. TH. WOLFF. *Farbe u. Lack* 1928, 190-1, 203-4 231-2, 240. G. G. SWARD

Preliminary report of the sub-committee of the Royal Academy of Arts on modern pigments and mediums. A. P. LAURIE, et al. *J. Oil Colour Chem. Assocn.* 11, No. 97, 60-9(1928).—This report treats briefly of the following: prepg. of canvas for painting, deepening of tone of paints on aging, yellowing of linseed and other drying oils, and cracking of oil pictures. Deepening in tone is due to the slowly increasing index of re-

fraction of the dried linseed oil film and its yellowing. A table is given of the pigments least affected by changes in linseed oil. A hard finishing coat, *i. e.*, one that contains either a high pigment percent or a hard gum varnish, when used over a soft undercoat, is conducive to film cracking. A table of pigments is given ranging from low oil absorption at the top to high at the bottom. Those belonging to the upper $\frac{1}{2}$ are best used in the undercoat, while the lower $\frac{1}{2}$ are rather for the finishing coat. The best varnish for protecting the surface of a picture is beeswax dissolved in turpentine, brushed thin, dried 2 weeks and polished with silk.

R. J. MOORE

Application of methods of dyestuff analysis to the examination of pigments and lakes. ARTHUR G. GREEN. *J. Oil Colour Chem. Assocn.* 11, No. 92, 38-48(1928).—The principal chromophoric divisions used in pigments and lakes are discussed. The dyestuffs used are listed under the following general groups: insol. azo, acid, basic, mordant and vat. Procedure in investigating pigments and lakes is given and a table furnishing a complete scheme of analysis.

R. J. MOORE

Manufacture and properties of superdispersed minimum. J. H. FRYDLENDER. *Rev. prod. chim.* 31, 441-5(1928).—Superdispersed red lead is obtained by evapn. and condensation of litharge. Different processes in commercial use are mentioned.

P. THOMASSET

Large scale titanium pigment production based on old laboratory process. BRUCE K. BROWN. *Chem. Met. Eng.* 35, 427-8(1928).—A description of the Blumenfeld process and plant as operated by the Commercial Pigments Corp. at Baltimore, Md.

R. J. MOORE

Chrome yellow and its practical use. C. R. HALLE. *Farbe u. Lack* 1928, 300-3.—Review and photomicrographic study.

G. G. SWARD

Painting tests on panels impregnated with zinc chloride or creosote for highway markers and factory construction. H. A. GARDNER. *Am. Paint Varnish Manufrs. Assocn. Circ.* No. 334, 588-98(1928); cf. *C. A.* 21, 180.—Examm. of test panels exposed 20 months proved that freshly creosoted wood may not be satisfactorily coated with white paints made on a linseed oil base. The application of many types of primers (red lead, Al powder, Zn dust, etc.) failed to prevent bleeding through of the creosote. It is suggested that creosoted wood which has been weathered a year or so may be painted. Many coatings used over $ZnCl_2$ -treated panels gave satisfactory results. A series of new accelerated tests to det. the efficiency of paints on impregnated yellow pine for mill construction is described.

R. J. MOORE

A photographic study of a sign board. H. A. GARDNER. *Am. Paint Varnish Manufrs. Assocn. Circ.* No. 333, 583-7(1928).—Photographs (enlarged) and photomicrographs are presented to show the protective action of painted letters on a cypress panel exposed to weathering for 11 yrs.

R. J. MOORE

Paints for shingle roofs. Results of exposure tests conducted for 11 years. H. A. GARDNER. *Am. Paint Varnish Manufrs. Assocn. Circ.* No. 332, 569-82(1928).—Tests indicate that highly pigmented linseed oil paint made with mineral pigments which are not reduced by heat will weather satisfactorily upon and preserve shingle roof surfaces. The efficiency of shingle paint is shown in a series of photographs of shingles which have been exposed 11 yrs.

R. J. MOORE

Paints for metal. Iron, steel, copper, galvanized, tinned and other metal surfaces. H. A. GARDNER. *Am. Paint Varnish Manufrs. Assocn. Circ.* No. 331, 509-68(1928).—The relative degrees of usefulness of various pigments for metal protective paints are presented. Methods of painting various types of metals are given, and results of some recent tests are illustrated with photomicrographs. A brief history is finally given of some of the important paint tests made in America.

R. J. MOORE

Chipping and abrasion tests for paint coatings on metal. A. D. CAMP. *Ind. Eng. Chem.* 20, 851-2(1928).—Chipping and abrasion tests are used to det. relative toughness and durability of paints for Al alloy. The chipping test is made by dropping on the test panel under standard conditions a series of standard tools, and observing the extent and character of the impression made on the coating. The abrasion test is made by detg. the no. of revolutions of the panel, under a standard abrading disk, which are required to wear through the paint film. Details of method, equipment and interpretation of results are given.

R. J. MOORE

Paints on Jirotko-processed light metals. G. KUTSCHER. *Farbe u. Lack* 1928, 313-4.—Al panels with and without the Jirotko treatment were painted with red lead and then immersed in the North Sea. After 8 months the former were in excellent condition while the latter were severely corroded.

G. G. SWARD

Protective coatings for duralumin and other aircraft alloys. H. A. GARDNER. *Am. Paint Varnish Mfrs. Assocn. Circ.* 330, 482-508(1928); cf. *C. A.* 21, 657.—Tabular

results are given of the relative efficiencies of over 50 protective coatings on Al alloys. Photographs and photomicrographs are used in illustration. After 2 yrs. slightly accelerated exposure the following gave good results in linseed oil vehicles: dry lamp black, Zn chromate and a mixt. of Fe_2O_3 and Zn chromate. Drying ovens or ultra-violet light are suggested to speed the drying of such paints. Special rubber-coated (electrolytic) duralumin sheets gave promising durability results. Spraying the metal with Al gave a rough, spongy surface.

R. J. MOORE
Coating for protection against rust and weather. M. BERGER. *Apparatenbau* 40, 166-7 (1928).—"Gummolin," a linseed oil prepn., has given excellent results. J. H. M.

Some questions concerning the rust prevention problem. HANS WOLFF. *Farbe u. Lack* 1928, 299.—Rust prevention is not related to weatherability or thickness of a film but probably to a layer of the effective substance deposited from the paint onto the metal as a result of interfacial forces. Wolff accounts for the abnormally high vol of highly dispersed red lead paints by the formation of soaps about the particles.

G. G. SWARD
Problems in the painting of ship bottoms. D. SCHULZ. *Farbe u. Lack* 1928, 250-2, 267, 277, 291.—A review.
G. G. SWARD

Composition of zinc chrome. B. A. ELLIS, J. J. FOX AND J. F. HIRST. *J. Oil Colour Chem. Assn.* 11, No. 96, 194-8 (1928).—The confused state of the literature as to the formula for Zn chrome is reviewed. The divergence in compn. is due to variations in manuf. and to incomplete methods of analysis. An analytical method is recommended and results are given on com. samples. So far as any formula can be assigned to Zn yellow of av. com. grade, the analyses would indicate $5\text{ZnO} \cdot 4\text{CrO}_3 \cdot \text{K}_2\text{O} \cdot 4\text{H}_2\text{O}$. The $\text{NH}_4\text{-Zn}$ yellows give approx. $2\text{ZnO} \cdot 2\text{CrO}_3 \cdot (\text{NH}_4)_2\text{O} \cdot \text{H}_2\text{O}$.

R. J. MOORE
Precipitation of zinc chromate. J. L. BUCHAN AND J. J. FOX. *J. Oil Colour Chem. Assn.* 11, No. 96, 198-202 (1928).—Methods of prepn and analysis are given for the following Zn chromes: NH_4 , basic, K, Na and mixed. A discussion follows. R. J. M.

Study of the uneven nitration of nitrocellulose. P. A. BENEDICT. *Paint, Oil Chem. Rev.* 86, No. 7, 10 (1928).—This work was undertaken to study marked variations in viscosity of nitrated cellulose when dissolved in identical solvent mixts. Sol tests on individual nitrated fibers gave varied results, some parts dissolving, some swelling and some remaining unaffected. Individual cotton fibers, both long and short, were nitrated and the action was studied by photomicrographs. The action is very uneven, some parts of the fiber being more resistant than others.

R. J. MOORE
Studies in the drying oils. VIII. Absorption of liquids by oil gels. J. S. LONG, E. K. ZIMMERMANN AND S. C. NEVINS. *Ind. Eng. Chem.* 20, 806-9 (1928).—The adsorption of various liquids by extd. heat-bodied oil gels and by extd. dry linseed oil films produces similar changes in phys. characteristics. Both show selective adsorption of fatty acids from soln. Also comparison of the heats of combustion of extd. and unextd. films and of the extd. oil offers further support to the premise that the liquid phase in a film is adsorbed rather than mechanically entrained. IX. Action of cold-blowing on linseed oil. J. S. LONG AND W. S. EGGE. *Ibid* 809-11.—Linseed oil was air-blown at 30° in the presence of various substances. Positive catalysts caused decrease in unsatn.; negative catalysts prevented this. The effect of previous heat bodying on the blowing of the oil gave results indicating that a combination of these treatments would yield a greater variety of useful industrial products. Each of these treatments accentuates a certain type of reaction. *Thioglycolic* acid is recommended as a reagent for quant. precipitation of metallic driers from oils or varnishes. R. J. M.

United States Government master specification for raw linseed oil. Bur. Standards, *Circ.* No. 361, 8 pp. (1928).

E. H.
United States Government master specifications for boiled linseed oil. Bur. Standards, *Circ.* No. 362, 8 pp. (1928).

E. H.
Oxidation of linseed oil. II. D. CHATAWAY. *J. Soc. Chem. Ind.* 47, 167-71 T, (1928).—Linseed oil in bulk was oxidized by passing O through it. The av. rate of the reaction at different temps. and the total vol. of O absorbed at time of gelling were studied. Above 100° gelation occurs immediately on the formation of a certain min. % of oxidized glycerides; at lower temps. gelation requires the formation of a larger %. Irregularities in the rate of absorption proved to be largely due to some impurity in the O, which could be removed by passing through SnCl_4 soln.

R. J. MOORE
Certain physical and chemical characteristics of flax seed and linseed oil. A. L. BUSHEY, L. PUHR AND A. N. HUME. *S. Dakota Agr. Expt. Sta., Bull.* 228, 11 pp. (1927).—The av. % of oil in flax increased regularly from the first to the last cutting. The I no. varied invariably with the oil content. Early harvested seed would have a lower

oil content, but the oil would possess better drying qualities. The oil content of 9 varieties of seed varied from 34.3 to 37.4%. J. J. SKINNER

The determination of wood oil. JOHANNES SCHIEBER. *Farbe u. Lack* 1928, 274, 286 7.—To 5 g. of the sample mixed with 5 g. of sand add with const. stirring 5–10 cc. ether contg. 2–10% SnCl_4 . Place the mixt. in a desiccator until solid (1–30 hrs.), then ext. with dry ether. The wt. of the unextd. matter represents the wood oil. Samples of less than 6% oil do not solidify but an increase in viscosity may be noted. SnCl_4 will effect solidification of wood oil in the presence of substances which inhibit the solidification with iodine. The max. error in 58 detns. was 20.4, the min. 0.0 and the av. 3.8%. G. G. SWARD

Observations on an August inspection of Florida tung oil groves and on the quality of American oil submitted to various varnish makers. H. A. GARDNER. *Am. Paint Varnish Manufs. Asscn. Circ.* No. 336, 620–36 (1928); cf. C. A. 21, 1193.—This inspection report indicates a healthy condition of the Florida tung trees with this year's crop possibly doubling last year's. Details as to soil, planting and cultivation are given together with information regarding cost factors. Reports from 25 varnish manufs. show the oil to be superior to the imported oil. R. J. MOORE

Making gloss oil in the pebble mill. D. DAVIDSON. *Paint, Oil, Chem. Rev.* 86, No. 5, 11 (1928).—A gloss oil paler in color than that produced in the varnish kettle can be made by grinding rosin, lime and thinner in a pebble mill. In making an enamel the pigment is also introduced into this initial grind. It is possible by this method to introduce more lime than is usually employed in the kettle gloss oil. R. J. M.

Chemistry of lead "soaps" made from litharge and neutral fat. S. H. DIGGS AND F. S. CAMPBELL. *Ind. Eng. Chem.* 20, 828–9 (1928).—When fats are treated with PbO in the absence of H_2O , no glycerol is formed and there is no appreciable H_2O or aldehyde liberated. The reaction, unlike that for fatty acid and PbO , is an addn. of 1 mol. of fat to 3 mol. of PbO . This addn. compound formula is in agreement with mol. wts. detd. by the f. p. method. R. J. MOORE

Malayan damars. II. T. HEDLEY BARRY. *J. Oil Colour Chem. Asscn.* 11, No. 96, 203–18 (1928).—Classification, analyses and comparisons are made of the various damars. Results are given of steam and destructive distn. of some damars. The chief obstacles to the systematic development of Malayan damars are the scattered nature of the trees and the inaccessible position of the best specimens. (Cf. C. A. 22, 2672.) R. J. MOORE

Phenol-formaldehyde resinification. I. JAN NOVÁK AND VOJTECH CRCH. *Ind. Eng. Chem.* 20, 796–801 (1928).—Three methods for the detn. of the degree of resinification are described: (1) measurement of the refractive indexes of the reaction mixt., without sepn. of the resinous part from the aq. liquid; (2) detn. of the viscosity of a soln. of the reaction mixt. in EtOH by means of the Ostwald viscometer; (3) detn. of "bromine value" of the reaction mixt. by dissolving the tested sample in AcOH , pptg. the resinous substances by the addn. of H_2O and titrating the filtered liquids according to Koppeschaar's method. The results are plotted to illustrate the course of resinification, and the mechanism of the reaction is described on the basis of these data. Condensation is found to occur almost during the whole period of resinification, while polymerization sets in after pptn. of the insol. resinous substances. The catalytic powers of different agents vary. They are divided into condensation catalysts (acidic) and polymerization catalysts (basic). R. J. MOORE

Valuation of rosin by its physicochemical constants. I. V. FILIPOVICH AND N. V. TUKHOVITZKII. *J. Chem. Ind. (Moscow)* 4, 875–80 (1927).—The criteria used for valuating rosin are chiefly color, acid number, sapon number and m. p.; in some cases moisture content, ash, insoly. in petroleum ether and alc. and I no. are also taken into consideration. Usually rosin is considered of good quality if it is of light color, has an acid no. of 145–80 (the higher the better), a sapon. coeff. differing but little from its acid no. and a high m. p. Yet all these const., even if identical for several diff. samples of rosin, do not indicate that the compns. are the same, since rosins are not definite chem. compds., but represent complex mixts. of various substances. For the purpose of finding a better-founded criterion of valuation of rosins, and being guided by the desire of getting at least an inkling of their compn., F. and T. undertook a comparative study of rosins of various origins. There were studied 7 Russian turpentine rosins, 6 Russian wood rosins, American turpentine rosins H and J and Hercules wood rosin F. The m. ps. of the American rosins were 65–72°, those of Russian turpentine rosins were 60–77°, those of Russian wood rosins 49–58°. There is no interdependence (correlation) between the m. p. of rosin and its other properties, or the proportion of its components. Thus the m. p. is not an essential criterion. The acid and sapon. values and the dif-

ferences between the 2 were then determined. The 3 American rosins had acid values 155-69, sapon. coeffs. 162-73, differences between the 2 being 4-10. Russian turpentine rosins had acid values 146-67, sapon. coeffs. 151-72, differences 3-7. Russian wood rosins had acid values 151-59, sapon. coeffs. 156-61, differences 0.8-5.0. However, it is not correct to assume that the smaller the difference between the acid no. and the sapon. coeff. the better the rosin. From the standpoint of *soap manuf.* the value of rosin depends on the quantity of its constituents which can be saponified and salted out, all the other constituents being a useless ballast; an increase of acid no. which is not due to a corresponding increase of substances which can be saponified and salted out is rather harmful and decreases the useful action of alkali. To det. the contents of substances which can be salted out, F. and T. utilizing the investigations of O. Aschan (cf. *C. A.* 15, 3097) and of E. Knecht and N. Maurice (cf. *C. A.* 20, 299) worked out the following method: Dissolve 5-10 g. rosin in 100-200 cc. of ether, pass the soln. through a weighed filter, wash the residue, which consists of mechanic admixts. and impurities, with ether, dry to const. wt. and weigh. The resinous substances are obtained from the filtrate after evapg. the ether and drying to const. wt. at 100°. Saponify the resin with double the theoretical quantity of 1% NaOH soln. and reflux 40-50 min. on a water bath. Ext. the soln. obtained 4 times with ether with energetic shaking in a separatory funnel in order to extract the unsaponifiable; wash the ether ext. with NaOH and with water, evap. the ether and dry to const. wt. at 100°. Salt out the saponified portion by means of a 36% NaCl soln., using 3 cc. of the latter to 1 g. of rosin. Filter the dry sodium abietate obtained, transfer into an Erlenmeyer flask and decompose with 1% H₂SO₄. Filter the cheese-like ppt. of resinous acids, wash with water, dissolve in ether, wash the soln. with water in a separatory funnel, transfer to a tared Erlenmeyer flask and weigh the pure saponified and salted out constituents of rosin after evapn. of the solvent and drying to const. wt. To det. the saponifiable which cannot be salted out treat the filtrate obtained after sepn. of sodium abietate 3-4 hrs. with a current of CO₂, filter the ppt. formed, transfer to a separatory funnel, treat with 1% H₂SO₄, extract with ether, wash the ethereal soln. with water, transfer into a weighed Erlenmeyer flask and weigh after evapg. ether and drying to const. wt. at 100°. The portion of the saponifiable which does not ppt. with CO₂ and thus remains in the form of Na salt of colophenic acid (O. Aschan) in the filtrate is pptd. from the latter by 1% H₂SO₄; filter by means of a weighed filter, wash with water, dry and weigh. After the sepn. of the hydroxy acid the filtrate contains the coloring matter, which can be detd. by extg. with water, washing and weighing. By this method were found the following values of the contents of substances which can be salted out: American rosins 71.44-83.40, Russian turpentine rosins 70.45-89.40, Russian wood rosins 80.03-85.92. Comparison of these figures with the respective acid and sapon. numbers showed that no adequate relationship exists; the reason is that many rosin components possessing the groups COOH and OH are not susceptible to salting out. The acid and sapon. values are even less reliable criteria than the m. p. On the other hand, the quantity of substances which can be salted out is a good criterion of rosin valuation for *soap and paper manufacturers*; it may be called the *usefulness coeff.* Another valuable criterion is the *alkali consumption coeff.*, i. e., the quantity of alkali neutralizing a given wt. of rosin; it is obtained by dividing the acid (or sapon.) number by the usefulness coeff. The petroleum ether-insol. content appears to be in some inverse relationship to the usefulness coeff. of rosin; thus, e. g., a rosin contg. 14.98% petroleum ether-insol. had a usefulness coeff. of 74.00%, whereas a rosin contg. 1.29% petroleum ether-insol. had a usefulness coeff. of 84.52, etc.

BERNARD NELSON

False equilibria with special reference to rosin solutions and gold size. R. P. L. BRITTON. *Oil Colour Trades J.* 73, No. 1540, 1220-2(1928).—The peculiarities of rosin dissolved in mineral spirits and in MeOH with reference to crystn. are discussed. Under the heading "gold size" a no. of methods of prepn. are outlined with a view to reducing the tendency of Pb linolate to yield ppts. Thermodynamic equilibria possibilities existing between the "superfused" and the cryst. varieties of varnish materials are indicated. A discussion follows.

Resinous composition. COURTNEY CONOVER (to The Selden Co.). U. S. 1,678,105, July 24. A resinous plastic compn. which is suitable for molding, coating or impregnating comprises the reaction product of glycerol, phthalic anhydride and furfural.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

The problem of methods for determining fats. A. TICHONOV. *Oil and Fat Ind.* (Russia) 1926, No. 6, 38–40; *Chem. Zentr.* 1927, I, 2869.—A study was made of ordinary methods for fat extn. by the Soxhlet app. and cold extn. to det. the part played by the time of extn. and the choice of solvent. The 2 methods give concordant results with Et_2O and with petr. ether. In the Soxhlet extn. 97.6% of the fat is extd. after 1 hr., and extn. is complete after 5–6 hrs. Cold extn. for 2–3 days exts. nearly all fat, and an additional 2 days exts. only a few hundredths of a percent more. Extn. in the Soxhlet app. is simplified by the use of a separatory funnel with a tube between flask and the Soxhlet app., which is described in the original. At the termination of the extn. the stopcock of the funnel is closed, the vapor of the solvent passes through the tube into the extn. app., and the condensed liquid collects in the funnel. The fat remaining in the flask can be weighed without transferring. Two new methods for detg. fats are also described, which give satisfactory results, but which must be perfected. The first of these serves for the detn. of the d. of extd. material in which fat or oil is present, while in the other method the fat is detd. indirectly by

weighing the extd. residue. It has the advantage that several detns. can be carried out simultaneously in a Soxhlet app. C. C. DAVIS

Method of determining fat by the residue from which the fat has been removed. N. YERMOLAEV. *Oil and Fat Ind.* (Russia) 1926, No. 10-11, 25-8; *Chem. Zentr.* 1927, I, 3157.—The oil or fat content of a substance can be detd. not only from the extd. oil or fat but also by difference of the extd. residue. A series of analyses was made with a view to detg. the precision of the difference method. The chief source of error is the increasing water content of the substance and the extn. shell before and after the extn. Since abs. drying is inconvenient because of the hygroscopic properties of the filter paper of the extn. shell, a shell contg. the extd. substance is weighed as a control. Any difference in wt. of the control shell before and after extn. is used to calc. by proportion the shell employed in the analysis, and is regarded as hygroscopic moisture. The values obtained agree well with those of the ordinary methods of detn., the deviations being less than 0.5% in 62% of the cases. The method has the advantage that several substances can be detd. simultaneously in 1 extn. if they are wrapped individually in filter paper in the extn. shell. C. C. DAVIS

The fat in the residual material remaining after the unwinding of the silk cocoon. J. JELAKOV. *Oil and Fat Ind.* (Russia) 1926, No. 10-11, 35; *Chem. Zentr.* 1927, I, 315-6.—The unwound cocoon contains about 25% of a fat with d. 0.919, sapon. no. 191.0, I no. 105.2, R.-M. no. 3.24, mol. wt. 283 and m. p. 30°. It is suitable for the production of soap, and the residue, which contains P and 60% protein, is an excellent fertilizer. C. C. DAVIS

The prevention of autoxidation of vegetable oils and their fatty acids. V. NOVIKOV. *Oil and Fat Ind.* (Russia) 1927, No. 2, 17-20; *Chem. Zentr.* 1927, I, 3155.—Oleic acid of vegetable origin always contains small proportions of linoleic acid and has a tendency to oxidize or even ignite spontaneously. The rate of O absorption by pure linoleic acid in a thermostat and the action of various org. substances in retarding this oxidation were studied. To be of use technically a substance must be active in small quantities, it must not alter the properties of oleic acid; it must wash out with water in emulsification; and it must be capable of being washed out of wood and textiles by weak alkali lyes. β -Naphthol fulfils these requirements. Even 1% of this compd. prevents entirely the oxidation of linoleic acid in pure O to 60°. Technical expts. with wool balls which were impregnated with vegetable oleic acid and were heated at 60° confirmed these facts. Linseed oil contg. 1% β -naphthol did not change in I no. or in viscosity during 2 yrs. No attempt is made to explain the action of β -naphthol. A compilation of the most important works and patents in this field is included. C. C. DAVIS

Newer opinions of the reactions in the drying of fatty oils. JOHANNES SCHEIBER. *Z. angew. Chem.* 40, 1279-85 (1927); cf. C. A. 21, 184 --A review with 81 references. S. concludes that chem. reactions are necessary to produce the nuclei about which coagulation of the oil may take place. The drying of oils is a chemical-colloidal process, instead of a colloidal-chemical one as postulated by the gas coagulation theory of Auer. G. G. SWARD

Saponification with the Twitchell and Pfeilring reagents. G. PETROV. *Oil and Fat Ind.* (Russia) 1926, No. 6, 25-8, No. 7 8, 21-7; *Chem. Zentr.* 1927, I, 3156-7.—Comparative expts. were made with various aromatic thio fatty acids prepd. according to the directions of the Twitchell patents. The results show that the aromatic thio fatty acids of anthracene, phenanthrene, C_6H_4 , and xylene are less active than those of $C_{10}H_8$. An interchange of fatty acids in the reagent showed that cleavage agents from naphthalenesulfonic acid and the fatty acids of sunflower oil, linseed oil or train oil have about the same action. Nevertheless cleavage agents with a high oleic content show a greater activity and yield lighter fatty acids besides. Data on the Pfeilring cleavage agent, its methods of prepn. and its activity, and directions for the use of both reagents are included. C. C. DAVIS

The oil, candle and soap industry at the present time. S. FACHINI. *Atti congresso naz. chim. pura applicata* 2, 929-35 (1926).—A statistical review. L. T. F.

Further data on the necessity for drying seed. A. LOBASHOV. *Oil and Fat Ind.* (Russia) 1926, No. 1, 42-6; *Chem. Zentr.* 1927, I, 2251.—A predrying of flaxseed at 130-50° and a corresponding reduction of the water content to 1.5-2.5% diminishes by about 1% the quantity of oil retained in the oil-cake. Furthermore the seed may then be ground finer by milling. If the drying operation is carried out rapidly enough, drying of the oil in the seeds need not be feared. C. C. DAVIS

The distribution of oil in oil cake. A. LAPTEV. *Oil and Fat Ind.* (Russia) 1926, No. 10-11, 30-1; *Chem. Zentr.* 1927, I, 3154.—The oil content is in general higher in the middle than at the edges (0.7%) of oil cake. When cakes were pressed with a filter

cloth on one side only, the oil content was 6.8–7.4% higher on the side without the cloth. The thicker, longer and wider a cake is, the more the oil which remains in it. Filter cloth is very essential for obtaining a cake poor in oil, since it facilitates the draining of the oil.

C. C. DAVIS

The problem of obtaining average samples of oil cake. F. GOGOLEV. *Oil and Fat Ind.* (Russia) 1926, No. 4–5, 46–9; *Chem. Zentr.* 1927, I, 2783.—The variations in the oil content in the middle and on the edges of oil cake, and in cakes from various positions in open Anglo-American presses with 16 plates, were investigated. The oil content is highest in the middle of the cake and diminishes away from the middle. In the cases investigated it was 7.03% in the middle and 8.03% at the edges. Oil cakes from different positions in the press showed the same oil content up to the uppermost layer, in which the oil content was approx. 0.5% higher than in the others. A further investigation of the influence of the time of pressing and of the kind of channeling of the plates is advisable.

C. C. DAVIS

Volumetric analyses of oil cakes for their oil content and moisture. A. LAPTEV. *Oil and Fat Ind.* (Russia) 1926, No. 4–5, 49–52; *Chem. Zentr.* 1927, I, 2869.—The finely divided substance is covered with Et_2O in a Soxhlet app. and let stand overnight. By doing this the time of extn. is reduced from 8 to 3–3.5 hrs. At the bottom of the app. is placed some wadding (with fat removed), which prevents carrying away of solid particles with the liquid, so that the latter need not be filtered. The Et_2O with its extd. oil is collected in a previously weighed flask, from which the Et_2O is expelled after the extn. The last traces of Et_2O are expelled in a drying oven by means of a current of CO_2 , after which the flask with the extd. oil can be weighed. The ability to weigh the extd. oil in the flask and not be obliged to transfer it to the weighing vessel means a great saving of time. The extn. app. and the drying oven are heated with incandescent lamps, so that danger of ignition is practically avoided, and the app. can be left to itself.

C. C. DAVIS

Oil from apricot stones. V. TEMNOV. *Oil and Fat Ind.* (Russia) 1926, No. 10–11, 67–8; *Chem. Zentr.* 1927, I, 3155.—Expts. started for the first time in Russia on the production of oil from apricot stones showed far from satisfactory results, since the material to be pressed which had been previously disintegrated was squeezed out between the plates. After double pressing the yield of oil was 37%, while 10% remained in the oil cake. The oil had the following const.: d. 0.915, I no. 101.4, sapon. no. 196, acid no. 311.

C. C. DAVIS

Avocado oil. GEORGE S. JAMIESON, W. F. BAUGHMAN AND RAYMOND M. HANN. *Oil and Fat Ind.* 5, 202–7 (1928).—The pulp of the varieties grown in Cal. and Fla. constitutes from 65 to 85% of the fruit and contains at least 80% fat on the dry basis. The refined and bleached oil is too dark for edible purposes. The const. are: d_{20}^4 0.9132, n_{20}^D 1.4700, acid no. 2.8, sapon. no. 192.6, unsapon. 1.6, I no. 94.4, acetyl no. 9.2, R.-M. no. 1.7, Polenske no. 0.2, satd. acids 7.2%, unsatd. acids 84.3%, I no. of unsatd. acids 101.2. The compn. of the oil from the cull avocado fruit in % of fatty acids is as follows: oleic 77.3, linolic 10.8, myristic trace, palmitic 6.9, stearic 0.6, arachidic trace, unsapon. 1.6. It could be used for soap.

E. SCHERUBEL

Determination of the oil content of flaxseed by the results of mechanical analysis of the purity. I. ORLOV. *Oil and Fat Ind.* (Russia) 1927, No. 1, 1–16; *Chem. Zentr.* 1927, I, 2783–4.—To save time and to avoid extn. analysis, a method of calcn. was devised for detg. the oil content of flaxseed. The values of the mech. purity test of the seeds were converted into the oil content, on the basis that 1% purity corresponds to 0.35% oil, so that seeds of 100% purity contain 35% of oil and 11% moisture. This relation is the av. of numerous analyses. An error enters into the calcns. because allowance is not made for oil-free impurities and other seeds (rapeseed, etc.). A modification of the formula is, therefore, recommended, in which the oil content is $0.355a + 0.05b$, where a is the content of pure flaxseed and b is the content of other seeds contg. oil.

C. C. DAVIS

The oil of lemon seed. FRANCESCO OCCHIPINTI. *Atti congresso naz. chim. pura applicata* 2, 945–50 (1926).—The oil extd. from the seeds of *Citrus limonum* has an amber-yellow color somewhat obscured by a greenish fluorescence. It is sol. in the common fat solvents and responds to the color reactions of Heidenreich, Bach, Hauchecorne and Brullé. O. obtained the following principal physical and chem. const.: d_{15}^4 0.922; congealing point -6° ; n_{20}^D 70.8; acid number 21.1; I no. 173.5; drying property 5%. The solid fatty acids which were sepd. by a modification of Varentrapp's method melted at 55.5–56°, had an acid number of 221.7 and a mean mol. wt. of 263.8. The liquid fatty acids had an I no. of 134.3, an acid no. of 199.4 and a mean mol. wt. of 181.3.

L. T. F.

The composition of hydrogenated rapeseed oil. ANON. *Oil and Fat Ind.* (Russia) 1926, No. 2-3, 51; *Chem. Zentr.* 1927, I, 2251-2.—The compn. of a hydrogenated rapeseed oil from Odessa was investigated (1) by the Reimer and Will method involving extrn. of the Zn salts of the fatty acids with Et_2O , and (2) by sepgg. the fatty acids with a satd. soln. of stearic acid in EtOH , according to the Hehner and Mitchell method. The sample contained 10.4% behenic acid, 33.8% stearic acid, 41.6% erucic acid and 11.3% rapinic acid. Data on the phys. and chem. const. of the oil are given in detail in the original.

C. C. DAVIS

Purification of sunflower oil by means of clays. L. M. LYALIN AND N. A. VARIGIN. *J. Chem. Ind. (Moscow)* 4, 882-5(1927).—The purpose was to study the adsorptive capacity of various clays in relation to sunflower oil, the best conditions of purification and the change of properties of the oil after the action of the clays. The expts. have shown that Glukhov white kaolin had the greatest adsorption capacity, and Glukhov yellow kaolin the next. The 2 Glukhov clays also had the greatest bleaching power; the power of floridin was weak. The clays used should be as finely pulverized as possible, since expts. show that their adsorbing power is thereby greatly increased. The quantity of clay used need not be above 10% of the quantity of oil, as expts. show that an increase beyond this proportion has little effect. The most favorable temp. for the bleaching operation is 75-90° for sunflower oil and 40-60° for cottonseed oil. It is advisable to neutralize the oils before bleaching. The best temp. for drying Glukhov kaolin before use is 275-400°. It is sufficient to stir Glukhov kaolin with sunflower oil for 30 min.; a more prolonged contact has no effect. The contact of the air in the course of the bleaching operation has no unfavorable effect. After use, the clays can be regenerated by boiling with NaOH for an hr. followed by repeated washings with water and drying by calcination. Sunflower oil, after being bleached by clays, has a lower acidity, whereas the sapon. coeff. and I no. remain unchanged. If the oil acquires an unpleasant taste and odor on being bleached with clays, this can be remedied by blowing superheated steam through the oil.

BERNARD NELSON

Wood oil and its many uses. WALTER OBST. *Allgem. Öl-Fettztg.* 24, 401-2; *Chem. Zentr.* 1927, II, 1631.

F. H.

Cod-liver oil. E. M. BAILEY, HELEN C. CANNON AND H. J. FISHER. *Conn. Agr. Expt. Sta., Bull.* 295, 334-7(1928).—Twenty samples of cod-liver oil were examd. with reference to I and sapon. nos., free fatty acids, unsaponifiable matter and vitamin content. The chem. data were inconclusive. The Drummond color test for vitamin A was found to correlate fairly well with vitamin A potency as detd. by standard U. S. P. animal feeding tests. The color technic may be relied upon to give indices of relative concns. of vitamin A in cod-liver oil. Six samples gave a color value of 5 or less; 9 samples ranged from 5 to 10; 2 samples ranged from 10 to 20, and 3 samples showed color values above 20. The color values could be checked very closely on repeated tests. One cod-liver oil ext. which gave no color with SbCl_3 was found to be of very low vitamin A potency. The basal test ration as now recommended by the U. S. P. assay method could be improved by the addn. of vitamin A-free fat or oil. The present ration was not eaten well by exptl. animals, especially when they were in a weakened condition.

C. R. FELLERS

Halphen's reaction. J. PIERAERTS AND ÉMILE SIMAR. *Mat. grasses* 20, 8222-4 (1928).—The use of open tubes causes the emanation of harmful gases, to which the operator is inevitably exposed. An app. permitting the collection of gases under water or by condensation complicates the reaction to a too great extent. P. and S. recommend the use of sealed tubes immersed in a const.-level water bath kept at boiling temp. for one hr. Results obtained by this method (of which the details are given) on oil from fresh seeds of *Hibiscus manihot* are reported.

P. A. THOMASSET

Studies in photochemistry. I. The Halphen reaction. A. J. PACINI AND R. W. CROSBY. *Clin. Med.* 35, 403-6(1928).—Cottonseed oil exposed to infra-red radiations loses its ability to give the Halphen reaction. The phenomenon appears to be related to the intensity of the radiation and to the time of exposure.

M. H. SOULE

Sulfonation of textile oils. E. L. FLETCHER. *Proc. Am. Assoc. Textile Chem. Colorists* 1928, 203-5; *Am. Dyestuff Rept.* 17, 475-7.—The procedure of sulfonation is described. Turkey Red oils must be of a high purity to meet the present conditions of storage and usage. The current Turkey Red oils are judged mainly by their ability to stay in soln. in acid and salt solns. This, however, is not sufficient. The max. amt. of the original glyceride should be broken up and this necessitates carefully designed processing units and ample technical supervision.

L. W. RUCOS

Determination of the water content according to Markussön. A. LAPTEV. *Oil and Fat Ind.* (Russia) 1926, No. 10-11, 31-2; *Chem. Zentr.* 1927, I, 3157.—To test methods

which are based on the expulsion and distn. of the water with xylene, comparative detns. were made with the drying oven. The results show that both methods give values which differ by 0.3% at the most. One condition conducive to precise values is to weigh as large a sample as practicable with a large quantity of xylene. C. C. D.

Progress reports in the soap industry. II. Yellow spots. J. DAVIDSOHN. *Chem. Lab. Berlin Schöneberg. Chem. Umschau Fette, Öle, Wachse u. Harze* 35, 166-9 (1928); cf. C. A. 22, 1697.—A review of the literature in which the following causes of yellow spots are non-critically discussed; the use of lavender oil as perfume; the use of hardened oil and of cottonseed oil; sudden chilling in the cooling presses; traces of heavy metals (Cu, Fe) and incomplete sapon. D.'s method of cold sapon. is said to assure complete sapon. P. ESCHER

Analysis of soap. J. DAVIDSOHN. *Oil and Fat Ind. (Russia)* 1926, No. 6, 31-6; *Chem. Zentr.* 1927, I, 2870.—The paper deals with sampling, detns. of moisture, total fat and free fatty acids, and the calcn. of the yields of soap from 100 kg. of fat. II. *Ibid* No. 7-8, 42-9; *Chem. Zentr.* 1927, I, 1386-7; cf. C. A. 20, 2912.—Methods of analysis are given comprising detns. of unsaponified fat, unsaponifiable components, alkali combined with fatty acids and with resin acids, total alkali, pure soap, free alkali, alkali carbonates, fillers, silicates, NaCl, KCl and rosin. The importance of the detn. of combined and total alkali in soap analyses is discussed. C. C. DAVIS

Special manufacturing of soft soaps. I, II and III. ROBERT KRINGS. *Allgem. Öl- Fettztg.* 24, 110-11, 140-1, 197-9; *Chem. Zentr.* 1927, I, 2783.—The material should not contain more than 1% unsaponifiable matter and be free of "distillation odor" since it is not easily covered. The importance of using the correct quantities and of carefully operating are emphasized. A. L. HENNE

Soap and washing powders. F. KASSATKIN. *Oil and Fat Ind. (Russia)* 1926, No. 10-11, 57-8; *Chem. Zentr.* 1927, I, 3157.—The works of Markuse and of Shadin are criticized. Washing powders contg. Cl or O are objectionable because of their destructive effect on clothes. Pure soap chips or flakes, with, if desired, the addn. of soda, are recommended. C. C. DAVIS

The problem of the preparation of washing powders. M. MARKUSE. *Oil and Fat Ind. (Russia)* 1927, No. 1, 27-9; *Chem. Zentr.* 1927, I, 2869.—Calcns. show that it is disadvantageous to use pure soap powders for washing clothes, since a great part of the soap soln. is consumed by the Ca salts of the wash water. The prepn. of compounded soap powders which contain not less than 25% fatty acids is recommended. Several analyses of "Persil" are shown for comparison. C. C. DAVIS

Suitable soaps for silk mills. FRED GROVE-PALMER. *Oil and Fat Ind.* 5, No. 7, 194-201 (1928).—No soap which has a hard fat for a base can safely be used for silk and no soap whose 1% soln. will jelly when cool is suitable. Likewise rosin soap is injurious on account of yellowing the fiber. Three kinds of soap have proven excellent for boiling off silk: (1) A pure oil soap analyzing 65% fatty anhydrides, 8% combined alkali, 25% H₂O and 0.3% or less free NaOH. (2) Monopol soap, made from sulfonated castor or linseed oil, analyzing as follows: fatty anhydrides 65-75%, combined alkali 3%, free alkali none, H₂O 12-15%. (3) Marseilles soap, made from olive oil foots and analyzing 60-63% fatty anhydrides, 7% combined alkali, not over 0.3% free NaOH, and 26-30% H₂O. E. SCHERUBEL

Detergent experiments on cotton. ROBERT M. CHAPIN. *Oil and Fat Ind.* 5 No. 7, 208-12 (1928); cf. C. A. 22, 2284.—Cotton fabric was soiled with an ointment of lamp black and vaseline, lard, or medicinal mineral oil; after washing in a special machine the residual soil was evaluated by a colorimeter used as a reflectometer. Of pure Na laurate, myristate, palmitate, stearate and oleate the latter was the most powerful up to 40° while palmitate took first place at 60° and stearate at 80°. Addition of sufficient appropriate fat solvent enhanced detergent power. In parallel with C.'s findings on emulsification, excess fatty acid enhanced detergent power while excess alkali decreased it. Other resemblances between emulsification and detergency were not distinct. E. SCHERUBEL

Biological assay of cod-liver oil (ADAMS, McCOLLUM) 11B. Valuation of rosin [for soap manufacture] (FILIPOVICH, TUKHOVITZKI) 26. Agitator for mixing oil with chemicals (U. S. pat. 1,678,225) 1. The chemical study of Malvaleae (Pieraerts, de Winter) 11D.

Extraction of oils. PERFECTION COMPANY. Fr. 632,853, April 13, 1927. An app. is described for extg. oil from animal matter such as waste from butcheries, the waste being reduced to small pieces, heated to below 100°, macerated and filtered.

Apparatus for extraction of palm oil or other oils with solvents. C. DOWNS and R. A. BELLWOOD. Brit. 280,986, July 21, 1926.

Apparatus for extracting oil from cod livers by treatment with steam. JAMES A. PATCH. U. S. 1,678,123, July 24.

Sulfonation of oils, etc. CHEM. FABRIK STOCKHAUSEN & CIE. Fr. 632,738, April 13, 1927. Sulfonated oils, fats, etc., are treated with weak saponifying agents such as dil. acid or H₂O. The sulfonation may take place in the presence of indifferent solvents such as C₂HCl₃, and the acid of above 30°C is added as quickly as possible with intensive cooling.

Soap. ARTHUR E. HATFIELD and EUSTACE A. ALLIOTT. Can. 281,881, July 24, 1928. Oleic acid is treated with an alk. soln. (K₂CO₃, Na₂CO₃, KOH, NaOH or NH₄OH) and there is incorporated a mixt. of cyclohexanol and a chlorinated hydrocarbon as stabilizing agent.

Soap. ADOLF WELTER. Can. 282,112, July 31, 1928. A dry non-caking and readily sol. soap in the form of threads formed by forcing pure curd soap through nozzles of at most 1.5 mm. diam.

Flakes of soap and other products. JACOTIN and BINOCHÉ FILS. Fr. 632,413, July 27, 1926. Soap and other products are made into rectangular flakes by spreading in a layer on a traveling band and cutting in parallel lines, after which the soap leaves the band and is cut perpendicularly by blades on a wheel rotating at an appropriate speed.

28 SUGAR, STARCH AND GUMS

F. W. ZERBAN

Calcium-free juices. L. VAN DER HEIDE. *Chem. Weekblad* 25, 274 (1928).

The relation between the p_H and the Ca content of solns. contg. (a) lime, (b) lime and soda, (c) lime and Ca salt and (d) lime, Ca salt and soda, and through which CO₂ is passed has been calcd. It has been found that: the min. Ca content in c is not always reduced to the min. found in a on the addn. of the equiv. quantity of soda; the p_H near which the min. Ca content is found in c is dependent on the nature and quantity of salt present, and, in general, is not equal to the p_H in a . A high value for the min. Ca content does not require a low p_H ; the further the p_H in c is from the p_H in a the less is the equiv. quantity of soda sufficient to remove the Ca completely from the soln.; the p_H in a is little influenced by the addn. of the soda required for the removal of the Ca. The possibility is suggested of treating Java cane juices with soda in order to obtain Ca-free juices.

A. L. HENNE

Electrical installations in sugar mills from the standpoint of safety. G. JÖBIS. *Arch. Suikerind.* 36, 383-412 (1928).—Precautions for installing and manipulating elec. plants in sugar mills are discussed.

P. R. PEKELHARING

The factor of the Siegert formula for bagasse. G. J. SCHOTT. *Arch. Suikerind.* 36, 420-8 (1928).—The factor in the Siegert formula is const. for coal, but variable for bagasse on account of the high moisture. A graph computed from the moisture of the bagasse and the CO₂ of the flue gases is given.

P. R. PEKELHARING

The reducing capacity of adsorption carbons. JOSEF VASATKO. *Z. Zuckerind. cecho-slovak. Rep.* 52, 221-6 (1928).—The importance of activated carbons for the sugar industry lies in their great adsorption capacity, their action as an efficient filter aid and the important property of possessing a marked power of reduction. In a former study (*C. A.* 22, 2287) V. observed that the reducing power of adsorption carbons may play an important role to explain the decompn. of sucrose. In the purification of sugar liquors adsorption of coloring matter is accompanied by simultaneous reduction reactions which place the sucrose, especially at higher temp., in danger of decompn. V. decided to measure the reducing power by treating 1-6 g. of each of the 12 carbons under consideration for 3 hrs. at 20° with 100 cc. of an acidified soln. of FeCl₃ contg. 103.5 mg. of Fe^{III} and detg. in the filtrate the relative proportion of

Fe^{III} and Fe^{II}. Carbons distinguished by a higher power of decompn. of sucrose were characterized by a lower reducing power for ferric salts and *vice versa*. He divides the carbons into two groups. To the first, of higher reducing power, belong: Carbo Animalis Supra Norit 2 x, 3 x, 5 x, Polycarbon, Standard Norit and Superior Norit. This group comprises only gas activated carbons. The second group, of lower reducing power, includes: Anticromos, Carboraffin, Blood char, Carboraffin H, Bone char K. In this group with the exception of 2 animal carbons, all carbons are made by impregnation processes. Great importance should be laid in the selection of an activated carbon by also considering the reducing power. F. R. BACHLER

Yield formula Winter and P. G. H. C. PRINSEN GEERLIGS. *Arch. Suikerind.* 36, 59-62(1928).—Comments on Sylmans' formula expressing the tech. result (C. A. 22, 1699). Postscript. C. SYLMANS. *Ibid* 62-4.—Reply to Prinsen Geerligs. H. C. PRINSEN GEERLIGS. *Ibid* 367.—Answer to Sylmans. P. R. PEKELHARING

Commercial dextrin. S. R. TROTMAN. *Dyer, Calico Printer* 60, 36, 59(1928).—A general article, dealing with the different types of dextrin, methods of analysis and manu. RUBY K. WORNER

Note on the estimation of starches. W. H. BOAST. *Chemist-Analyst* 17, No. 3, 15(1928).—To det. starch in bond papers and in patent, white-fiber boards, the usual practice is to follow directions furnished by the Technical Association of the Pulp and Paper Industry. Difficulty was encountered in the final titration with Fehling or Benedict reagents. The following procedure although somewhat longer has been found more satisfactory. Ext., hydrolyze and neutralize as in the standard method. Transfer 2 ml. of the hydrolyzed starch soln. to a Folin sugar tube. To a similar tube add 2 ml. of standard sugar soln. contg. 0.2 mg. of dextrose. To each tube add 2 ml. of alk. Cu tartrate soln. Place both tubes in boiling water and keep them there for 6 min. Cool with cold water and add 2 ml. of alk. phosphate molybdate soln. After the Cu₂O has dissolved, dil. to the 25-ml. mark, mix and compare the color of the unknown soln. with the standard in the colorimeter set at 20 ml. Calc. the dextrose found in terms of starch. W. T. H.

The chloroform test for the valuation of the quality of various starches. WILHELM PLAHL. *Z. Untersuch. Lebensm.* 55, 295-6(1928).—A brief discussion. W. J. H.

Grating machines in the manufacture of potato starch. SPROCKHOFF. *Z. Spiritus-ind* 51, 180-1, 188(1928).—A discussion of the possibilities in this field when fine grinding with the Excelsior mill is carried on. The mfg. processes which have com. application are also considered. C. N. FREY

Influence of oil-containing incrustations in the steam chambers of evaporators on the heat transmission and the capacity of the evaporators (SPOELSTRA) 13. Gas distribution in liquids by means of a rotating sieve (PSENICKA) 13. The occurrence of starch in oil-bearing edible nuts (GRIEBEL) 12.

HIRSCHFELD, W.: Tabelle zur Berechnung der Schmutzprozente bei Zuckerrübenlieferungen, Kartoffeln u. a. landwirtschaftlichen Erzeugnissen von 2 bis 65 Prozent für 500 bis 50,000 kg. Magdeburg: A. Rathke. 131 pp.

29—LEATHER AND GLUE

ALLEN ROGERS

Critical study of the biochemistry of soaking. II. Effect of time, temperature and hide proportion upon soak waters. EDWIN R. THEIS AND ELLIOTT LEE MCMILLEN. Lehigh Univ. *J. Am. Leather Chem. Assn.* 23, 372-97(1928); cf. *C. A.* 22, 2681.—Soak waters were analyzed to show state of combination of their N_2 content, N_2 distribution according to Haussman's scheme, and biochem. O_2 demand. Increasing time of soaking increases total ammonia, amino, and org. N. Protein N remains fairly const. Nitrates first decrease and then increase. Nitrites increase slightly. Melanin N decreases; basic N is practically const.; amide N increases; and non-basic N decreases with time. O_2 consumption increases. Soak waters are strongly reducing in character. With increased ratio of hide to water, all constituents increase in concn., without much change in their relations among themselves. All components are increased with increasing temp. H. B. MERRILL

Sulfide stains on white hides. G. W. SCHULTZ. *J. Am. Leather Chem. Assn.* 23, 356-61(1928).—These stains are commonly attributed to formation of FeS . While hides that have come in contact with Fe always show stains when treated with Na_2S , Fe is not the cause of most stains observed in practice. Stains are most noticeable in poorly cured skins, and the proportion of stained skins increases with the length of time the skins are stored. By pretreating skins with dil. $NaOH$ or sulfide-free $Ca(OH)_2$ soln. before putting skins in a sulfide lime, stains can be entirely prevented. This pretreatment cannot remove Fe, and skins deliberately treated with Fe are not improved by the treatment. *Conclusion:* Sulfide stains are caused by the interaction of S^{--} and some decompn. product of hide H. B. MERRILL

Comparison of several methods of hydrolysis in determining nitrogen in leather. R. W. FREY, L. J. JENKINS AND H. M. JOSLIN. Bur. of Chemistry. *J. Am. Leather Assn.* 23, 397-402(1928); cf. *C. A.* 22, 192.—Samples of 5 leathers were digested for 0.5-3.5 hrs.; using (1) the A. L. C. A. method (no catalyst), (2) HgO , (3) $CuSO_4$, and (4) $KClO_4$. Addn. of each catalyst decreased the time for complete digestion by about 1.5 hrs. Otherwise the results were identical by all 4 methods. H. B. MERRILL

The effect of free sulfuric acid on leather and methods for its determination. M. KEH AND G. LAUFEROWNA. Lab. Poln. Gerbereibetriebe Krakau. *Przemysl Chemiczny* 11, 389-96; *Chem. Zentr.* 1927, II, 661. H_2SO_4 in leather was detd. by extg. with distd. water in a separatory funnel until the tannin test was negative, then titrating with $NaOH$ (rosolic acid as indicator), and finally pptg. as $BaSO_4$. Precise results are, however, obtained only by the method of Balland-Maljean, which must always be used when the SO_4 concn. exceeds 0.25%. C. C. DAVIS

The dyeing of leather. J. W. LAMB. *Dyer, Calico Printer* 59, 228-9; 60, 8, 9, 50, 1(1928).—A general article, dealing with the difficulties of leather dyeing, selection of dyestuffs and methods of application. Some typical recipes are included. RUBY K. WORNER

Topping black leathers. CHAS. A. MCNEIL. *J. Am. Leather Chem. Assn.* 23, 361-72(1928).—A discussion of different methods of operating and of the dyes employed therein. H. B. MERRILL

Tanning materials. VITTORIO CASABURI. *Atti congresso naz. chim. pura applicata* 2, 972-91(1926).—A review of the application of cellulose waste (waste sulfite liquor and soda cellulose liquor) to tanning and a discussion of the application of "Alphachrom" for which the author claims superior results. L. T. F.

Some aspects of tanning, coloring, and fat-liquoring. AUGUST C. ORTHMANN. *J. Am. Leather Chem. Assn.* 23, 351-5(1928).—A discussion of these operations with reference to chrome calf leather. H. B. MERRILL

Tannin content of Alaskan mountain hemlock (*Tsuga mertensiana*). P. B. DAVIDSON AND E. C. SHERRARD. U. S. Forest Products Lab., Madison, Wis. *J. Am. Leather Chem. Assn.* 23, 371-2(1928).—Pieces of bark 6 in. \times 6 in. were cut from 4 sides and 4 heights on 16 trees, making 256 pieces. The entire sample was ground and mixed. The sample was extd. by the A. L. C. A. method. Eight analyses of the ext. show the following averages: solids 26.81, sol. matter 21.39, non-tannin 9.18, tannin 12.21%. H. B. MERRILL

The drying of glue and gelatin. F. SAUER. *Kunst-dünger- u. Leim-Ind.* 24, 143-5, 171-2; *Chem. Zentr.* 1927, II, 663.—Diagrams show the influence of temp., size of batch and concn. of gelatin or glue on drying, in which the abscissas represent the no. of hrs. and the ordinates the diminishing wt. The results of Gerike (*Kolloid-Z.* 17,

78) show breaks in the dehydration curves at 70% and at 94% dry gelatin content on account of a firm union of water, and correspondingly in the present work the drying of larger sheets of glue involves at least 2 stages. Preliminary channel drying first at low temp. and then at 60° is recommended because of the lower m. p. of the glue or gelatin with an initial high water content.

C. C. DAVIS

Tanning with mixed tanning agents. R. ALCALAI. Brit. 281,292, Nov. 23, 1926. Vegetable tanning materials are mixed with a normal Cr salt and with an Al salt in such proportion as would be insufficient for tanning if used alone.

Wool and hair stripping. ROGER CAUJOLLE, LOUIS BARRIÉ and GEORGES DE CROZALS. Fr. 632,558, July 30, 1926. A compn. used for stripping skins of hair or wool contains KOH, vegetable oil, ammonia, oil of turpentine, oil of mirbane and talc.

Glue. MARCEL KOVÁCS and MICHAEL MESANAVITS. Fr. 632,380, July 23, 1926. Glue is made by adding flour of chestnuts to the ordinary constituents.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Patent review. CARL BÖHM V. BORNEGG. *Kautschuk* 1928, 134-6; cf. C. A. 22, 2489.—Numerous recent patents of various countries on the use of latex, raw rubber, mixing, vulcanization and manufactured products are itemized. C. C. DAVIS

The influence of some gas blacks on the properties of rubber mixtures. [FIRMA] ANTON ANDRÉ SOHN. *Kautschuk* 1928, 139.—Measurements of the particle size of C blacks gave the following values: Brand M and St. (A.A.S.), 60% of 15-40 μ , 38% of 40-90 μ ; Brand No. 200 (A.A.S.), 30% of 15-40 μ , 68% of 40-70 μ ; American, 65% of 15-40 μ , 35% of 40-70 μ ; Thermax, 20% of 15-40 μ , 73% of 40-100 μ . It is claimed that the A.A.S. blacks impart just as good properties to rubber mixts. as American blacks.

C. C. DAVIS

Yellow ochre in the presence of hydrogen sulfide. GORDON EASTWOOD AND A. M. MUNRO. *Chem. Eng. Mining Rev.* 20, 322-3 (1928).—In some expts. on compounding yellow ochre into rubber, one of the rubber compds. came out gray in color instead of yellow. This was apparently due to the formation of a film of Fe₂S₃. On standing in the air this tends to revert back to Fe₂O₃.

W. T. H.

Behavior of rubber-plated apparatus toward organic solvents (BRESSER) 1. Benzine and alcohol recovery equipment (MÜLLER) 1.

Rubber. SOC. DU CAOUTCHOUC ANODEX. Fr. 632,144, April 5, 1927. To prevent liberation of gas at the cathode in the electrophoretic deposition of rubber, the surface of the cathode is formed of an easily reducible metallic oxide such as PbO₂ and the cathode itself is preferably of Pb. An app. is described.

Rubber. THE B. F. GOODRICH CO. Fr. 632,474, Oct. 30, 1926. Addn. to 599,561. Fragments of rubber are treated with a sulfonyl chloride such as *p*-toluenesulfonyl chloride to produce a product plastic when heated.

Treating rubber latex. OMAR H. SMITH (to General Rubber Co.). U. S. 1,678,022, July 24. Latex is thickened with a buffer soln. such as a mixt. of primary and secondary Na phosphates, water-sol. substances are sepd. by stratification and a purified dispersible product is obtained.

Deposition of rubber. SOC. DU CAOUTCHOUC ANODEX. Fr. 632,143, April 5, 1927. The deposition molds used in the electrophoretic deposition of rubber are treated after use to recover their efficiency. If of unglazed clay they are heated to incandescence, or they are placed in an electrolytic bath contg. no colloid and current is passed in the opposite direction to that of the deposition, or they are washed under pressure with an alk. soln. or with the same electrolyte used for the impregnation of the molds in such a way that the liquid passes through the mold from the side which is turned towards the anode in the bath. If Ca salts have been added to the electrolytic bath the molds are washed with HCl. The amount of Ca salts required may be reduced by adding Mg compds.

Preserving rubber. J. TEPPERMA (to Goodyear Tire and Rubber Co.). Brit. 281,616, Nov. 30, 1926. The aging qualities of rubber are improved by the addition

of reaction products of phenols and amines such as phenyl α - or β -naphthylamine, α,β -dinaphthylamine, β,β -dinaphthylamine or diaminodiphenyldi- β -naphthylmethane. Directions are given for making these compds. and tables are given showing their effects when used with rubber.

Rubber composition. LORIN B. SEBRELL (to The Goodyear Tire and Rubber Co.). Can. 282,347, Aug. 7, 1928. Rubber is preserved by vulcanizing in the presence of a reaction product of an aldehyde and an amine formed at a temp. of approx. 0° and which is substantially a non-accelerator.

Rubber composition. LORIN B. SEBRELL (to The Goodyear Tire and Rubber Co.). Can. 282,348, Aug. 7, 1928. Vulcanized rubber is preserved by incorporating therein a reaction product of a crotonaldehyde and an aromatic amine, which is substantially a non-accelerator.

Rubber composition for facing molds. ADRIAN BAISH. U. S. 1,677,881, July 24. Molds suitable for forming rubber balls or other articles are faced with a compn. of rubber, S, Zn dimethyldithiocarbonate, methyl mustard oil, a filler, a "lightener" and a drier, *e. g.*, lime, clay, ZnO, MgO or MgCO₃ or asbestos.

Regeneration of waste rubber. WALDEMAR SCHEITHAUER. Fr. 632,990, April 20, 1927. See Brit. 270,675 (C. A. 22, 1706).

Vulcanizing rubber. WINFIELD SCOTT (to Rubber Service Laboratories Co.). U. S. 1,678,084, July 24. The CS₂ deriv. of the reaction product of diethylamine with paraformaldehyde is used as an accelerator in vulcanizing rubber with S. U. S. 1,678,085 specifies the similar use of the CS₂ deriv. of the reaction product of piperidine and furfuraldehyde.

Making and vulcanizing inner tubes of pneumatic tires. ERNEST W. MELVIN (to Fisk Rubber Co.). U. S. 1,678,015, July 24. Mech. features.

Rubber substitute. MORTIMER T. HARVEY. Fr. 632,454, Oct. 20, 1926. Addn. to 622,963. Cashew nut oil and glycerol are mixed and heated to about 245° to obtain a product similar to rubber, which can be vulcanized.

CHEMICAL ABSTRACTS

Vol. 22.

OCTOBER 10, 1928

No. 19

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

A colorimeter. KARL S. FELIX, HELMRICH AND WANDERSCHECK. *Wochschr. Brau.* **45**, 312-6(1928).—An app., fitted with a photoelectric cell, to det. color in malt worts and beers is described.

Extraction apparatus for liquids. J. FRIEDRICH. *Chem. Fabrik* **1928**, 91.—A new app. is described in which the usual glass spiral is replaced by a porous filter plate.

A continuous-extraction apparatus. H. L. MAXWELL. *Purdue Univ. Ind. Eng. Chem.* **20**, 871-3(1928).—The app. consists of two flasks connected together by a siphon and a vapor tube. A reflux condenser is in the neck of one flask. Solvent is placed in the flasks and the siphon tube filled. The flasks are then heated to boiling, after which the operation is automatic.

An automatic sample-collecting vacuum pump. E. R. WEAVER AND MARTIN SHEPHERD. *Bur. of Standards. J. Am. Chem. Soc.* **50**, 1829-35(1928).—The app. is an automatic Hg Topley pump, which acts as the backing unit to a high-speed Hg-vapor pump. The automatic control is accomplished by an arrangement of Hg displacement within an auxiliary cycle, which can be operated by a H₂O aspirator or a motor-driven vacuum pump.

New apparatus for boiling-point determinations. W. SWIENTOSLAWSKI. *Warsaw Polytechnic School. J. Chem. Education* **5**, 469-72(1928).—The app. consists of a Pyrex bulb connected with a vapor chamber, into which are inserted the thermometer and reflux condenser. Vapor bubbles in the bulb carry the liquid up and throw it out on the thermometer. In an improved form of the app., a Hg-filled glass thermometer well extends into the vapor space, so that any contact of the vapor with cork is eliminated. The app. is sensitive to 0.002°. In another form, the app. is provided with 2 consecutive vapor chambers, so that the boiling temps. of the soln. and of the pure solvent may be detd. simultaneously.

An efficient dehydrating apparatus for general use. WILBUR D. COURTNEY. *Oregon State Agr. College. Science* **67**, 653-4(1928).—To construct this unit, one end of a glass tube, bent into a U, is welded to the bottom outlet of a separatory funnel. The other end of the tube is welded to the small end of a test-tube (magazine tube). Near the top of this, and a little above the level of the stopcock in the separatory funnel, is inserted an overflow tube. Evapn. is minimized from the open end of the magazine by a cork, removable for charging or discharging purposes. At the bottom of the U is a drain-tube having a stopcock, allowing of complete drainage. The app. is best constructed of Pyrex glass, all rubber connections being eliminated, and is properly mounted on a ring-stand. Depending upon the size of the material to be dehydrated, object-glasses or cheese-cloth bags serve as containers, these being inserted in the magazine when filled. The stopcock in the separatory funnel may be so regulated that fluid passes through at the desired rate (a few cc. to l. per day) and into a dish.

The Rhode gas analyzer. RIZ. *Industriell. Norden*, No. 39, 309-10(Sept. 28, 1927); *Chimie et industrie* **19**, 1072-3(1928).—An illustrated description of the construction and operation of the app.

The Féry refracto-dispersometer. C. CHÉNEVEAU AND C. VAURABOURG. *Chimie et industrie* **19**, 787-92(1928); *Bull. soc. chim.* **43**, 374-84.—After a discussion of the importance and value of the detn. of n and of refractory dispersion, C. and V. describe the principle of the refractometer and of the refracto-dispersometer. The Féry refracto-dispersometer is essentially a refractometer with a chromatic objective, in which the ocular is provided with a small rotating disk perforated with holes which are covered by suitably selected monochromatic screens (corresponding more particularly to the green and indigo lines of the H γ spectrum). By turning the disk, any one of the screens

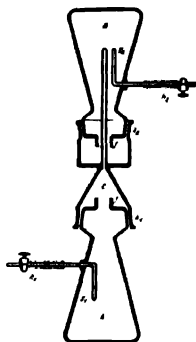

may be brought in front of the ocular and the n detd. for that particular wave length.

A. PAPINEAU-COUTURE

Apparatus for working with the exclusion of air or in a neutral atmosphere. P. DICKENS. Kaiser Wilhelm Inst. für Eisenforschung. *Instruments* 1, 311-2(1928).—

The app. can be evacuated through tube g_1 or filled with an inert gas through tube g_1 . The soln. to be treated enters the app. through g_1 . By reversing the app. the soln. can be filtered. Its use is suggested for the detn. of silica in carbon and low-silicon steels according to the Br method; of carbide C; of Cu, Zn and Mn as sulfide, for the formation of the addition products of CNBr to tertiary arsines, for the production of triphenylmethyl, etc.

D. GORDON

Automatic vacuum gages. L. SMEDE. Research Lab. Westinghouse Co. *Elec. J.* 25, 437-40(1928).—The development of the steel tank rectifier has created a demand for several types of automatic vacuum gages. The purpose of such gages is to turn on the vacuum pumps when the pressure reaches a certain definite value, prevent the power from being connected to the tank when the vacuum is too high, and cut the rectifier tank off of the line in case the pressure in the tank should rise to a dangerous value. Various types were investigated but the glow discharge type was found to be the best and was developed. The gage operates on

the principle of the variation of breakdown voltage of a gas with pressure. By properly choosing the distance between the electrodes and their size and shape, the gage can be made to operate over a range of from 1 to 40 microns. An Al cylinder 3 in. long and 1 in. in diam. is used as one electrode. The other electrode is a small cylindrical cap of graphite, about $1/16$ in. in diam. mounted on a small W rod sealed into the glass. In order to take care of irregular breakdowns which occur, a slow acting relay is used. Further details are given.

C. G. F.

A new model of condensation hygrometer. L. MARTINOZZI. *Staz. Aerologica Sperimentale Ufficio Presagi. Atti accad. Lincei* [6], 7, 389-93(1928).—The app was designed to eliminate the sources of errors inherent in hygrometers of the types of Regnault, Chistoni, etc. (cf. Ranzi, *Nuovo cimento* 4, (N. S.), No. 4 (1927)).

C. C. D.

Theory of magnetic separation. B. W. HOLMAN. *Trans. Inst. Chem. Eng.*, (advance proof), March, 1928, 3-11.—Theories of magnetism are briefly discussed in relation to the operation and design of magnetic separators, particular consideration being given to the influence of particle size, the shape of the pole pieces, the design of electro-magnets, the use of flux-meters and the detn. of permeability. B. C. A.

Dialysis of putrescible liquids. O. M. URBAIN. *Ind. Eng. Chem.* 20, 811(1928).—The app consists of a dialyzing tray of parchment paper contained in a metal dialyzing compartment, the lid of which is sealed in, and from which the air is aspirated by a current of N. The app. is kept at 0° by an ice jacket. The H₂O fed to the app. is first boiled to expel the O.

T. S. CARSWELL

Washing or dissolving various melts with water (VASSERMAN) 13.

Thermometer suitable for use on radiators of internal-combustion engines. C. L. BREEDEN. Brit. 281,781, Sept. 13, 1926. Structural features.

Use of substances of definite melting point, etc., in calibrating thermometers and pyrometers. N. M. HOPKINS. Brit. 282,424, Dec. 20, 1926.

Filter construction (with leaf filters carried on frames). J. H. DINE and C. H. BILLINGTON. Brit. 282,542, Nov. 15, 1926.

Filter for oil or other liquids. ERNEST J. SWEETLAND. U. S. 1,680,029, Aug. 7.

Filter for water or other liquids. GEORGE C. LEWIS (to Darco Sales Corp.). U. S. 1,678,676, July 31. See Brit. 262,328 (C. A. 21, 3493).

Filter for liquids or gases. A. PAHL. Brit. 281,879, Dec. 29, 1926. A woven wire screen is dipped in "liquid glass" or liquid enamel and then treated with charcoal, chalk or lime. After the coating has hardened it may be further treated with a reagent which will assist in the purification of the material to be treated or filtered. Exhaust gases from internal-combustion engines may be passed through filters some of which have been treated with caustic alkali and others with a soln. of Cl.

Fluid filter for absorption of "thermally active" rays. LOUIS BELL and WALTER

G. WOLFE. U. S. 1,681,276, Aug. 21. A soln. of ferrous NH_4 sulfate is used together with a soln. of $\text{Co}_2(\text{SO}_4)_3$, in "chromatic balance."

Bag filters for removing suspended particles from gases. MASCHINENFABRIK BETH A.-G. Brit. 281,994, Dec. 11, 1926. Structural features.

Apparatus for filtering and washing air or other gases. D. HALL, J. H. KAY and HALL & KAY, LTD. Brit. 282,233, Feb. 9, 1927.

Apparatus for cooling, humidifying and washing air. J. A. BROOKS. Brit. 281,914, March 21, 1927.

Centrifugal apparatus for removing dust from air, etc. WOODALL-DUCKHAM (1920), LTD., S. N. WELLINGTON and A. SCOTT. Brit. 282,258, April 5, 1927.

Suction device for removing dust from air or other gases. GEORG BÜHLER. U. S. 1,678,932, July 31.

Scraper for rotary continuous filters. ALBERT L. GENTER (to United Filters Corp.). U. S. 1,678,639, July 31.

Apparatus for washing and separating materials of different densities. FIRMIN BASCOUR (to Soc. anon. Cribla). U. S. 1,681,164, Aug. 21. An app. is specified which is suitable for treating coal to sep. it from shale.

Disintegrating and separating. ÉTABLISSEMENTS PILLARD FRÈRES. Fr. 633,996, May 6, 1927. An app. is described for disintegrating by shocks a soft material contg. harder granular particles with a view to sepg. the particles without destroying them. The shocks are caused by beveled knives turning at a high speed on an axle in a cylindrical container.

Heat exchange apparatus suitable for preheating air. NELS R. FORSSBLAD. U. S. 1,680,145, Aug. 7. Structural features.

Apparatus for distilling tar or other viscous materials on the surface of a heated coil. J. F. CARMICHAEL and J. F. CARMICHAEL & Co., LTD. Brit. 282,525, Oct. 28, 1926.

Dome construction for stills for tar, oils or other substances or for paper pulp digesters. BEACON OIL CO. and H. H. HEWETSON. Brit. 281,928, April 20, 1927. The main portion of the still is completely filled with liquid undergoing treatment, so that corrosive fumes are confined to the dome.

Apparatus for drying bagasse or other materials. FRANK L. ALLEN and ARTHUR D. FLOWER (to Edge Moor Iron Co.). U. S. 1,680,274, Aug. 14.

Apparatus for drying paper or other materials in long lengths. O. MINTON. Brit. 282,032, Dec. 10, 1926.

Heat exchange apparatus suitable for recording calorimeters. CHARLES V. BOYS. U. S. 1,680,850, Aug. 14.

Continuously operating flow calorimeter and indicator for gases. EDWIN X. SCHMIDT (to Cutler-Hammer Mfg. Co.). U. S. 1,678,918, July 3. A pair of positive displacement pumps serve to proportion the flow of a main stream of gas and of a test stream or continuous sample and a calorimeter and indicator indicate directly the caloric value of the sample.

Apparatus for regulating proportionate supply of chemical reagents. CHARLES H. SMOOT. U. S. 1,680,750, Aug. 14.

Apparatus for adding chemical reagents in regulated quantities to soften water or for other purposes. H. S. HATFIELD and UNITED WATER SOFTENERS, LTD. Brit. 282,168, Sept. 18, 1926. An analyzing or testing app. such as described in Brit. 264,237 (C. A. 22, 4) is combined with an app. for controlling the quantity of reagent added in accord with results of the test analyses. Numerous details are described.

Automatic recording apparatus for indicating proportionate changes in hardness of water (or other changes in liquids) by electrical conductivity tests. H. S. HATFIELD. Brit. 282,170, Sept. 20, 1926.

Apparatus for mixing different flowing liquids in determined volumetric proportions. H. KAUWERTZ. Brit. 282,503, Sept. 24, 1926.

Apparatus for making solutions. H. FRISCHER. Brit. 281,695, Dec. 6, 1926. Concentric perforated drums for material to be dissolved are placed within an outer vessel and may be surrounded with filtering material and provided with agitating blades. A plurality of drums may be used in series.

Perforated tube and associated apparatus for preventing froth being carried off with vapors from evaporating apparatus. SOC. DES CONDENSEURS DELAS. Brit. 282,022, Dec. 21, 1926.

Heat exchange device suitable for cooling compressed air. SVEN T. NELSON (to Sullivan Machinery Co.). U. S. 1,679,134, July 31.

Chemical autoclaves or other apparatus heated by electric induction. ARCHIBALD H. DAVIS (to National Aniline & Chem. Co.). U. S. 1,680,595, Aug. 14.

- Device for testing the heat conductivity of solids or fluids.** FRANCIS M. ROWAN. U. S. 1,680,638, Aug. 14.
- Continuous recuperator for use with various types of furnaces.** W. H. FITCH. Brit. 282,443, Dec. 18, 1926.
- Cooling drum for fatty emulsions or similar materials.** WILHELM G. SCHRÖDER. U. S. 1,679,685, Aug. 7.
- Electrically indicating apparatus for determining the moisture content of travelling webs of material.** A. ALLEN (to Atlantic Precision Co.). Brit. 281,693, Dec. 2, 1926.
- Spraying apparatus for coating metal, stone or other surfaces with glass, enamel or other coating materials.** A. PAHL. Brit. 281,885, Jan. 7, 1927.
- Apparatus for testing tensile strength and elongation.** ROBERT P. STEVENSON (to Henry L. Scott Co.). U. S. 1,679,751, Aug. 7.
- Gas-analysis apparatus.** SIEMENS & HALSKE A.-G. Brit. 282,080, Dec. 10, 1926. Structural features are specified of an app. for detg. the proportion of combustible gas in flue gases or other gas mixts. by burning them on an elec. heated wire and detg. the resistance of the wire.
- Gas-analysis apparatus.** CLARENCE H. PORTER. U. S. 1,681,047, Aug. 14. A single galvanometer is actuated by the combined effects of elec. devices responsive to the thermal cond. of burned and unburned portions of a gas sample.
- Apparatus for automatic control of valves of gas-producing plants, etc.** N. E. RAMBUSH and POWER-GAS CORP., LTD. Brit. 282,505, Sept. 27, 1926.
- Device for removing impurities from gases by centrifugal action.** L. L. BEURRIER. Brit. 282,420, Dec. 15, 1926.
- Catalytic apparatus for reactions between gases or vapors.** HANS HARTER. U. S. 1,678,778, July 31. An app. suitable for oxidizing NH_3 or for other reactions between gases or vapors comprises a propeller carrying Pt or other catalytic material with which the reacting materials are brought into contact.
- Gaseous discharge apparatus suitable for use as a rectifier.** CHARLES G. SMITH (to Raytheon Inc.). U. S. 1,679,449, Aug. 7. An anode comprising Ta is used with a coated cathode and an atm. of He.
- Apparatus (with superposed compartments and rotary atomizers) for effecting contact of liquids with gases.** S. WRIGHT. Brit. 281,958, June 9, 1927.
- Apparatus for treating gases with a counterflow of liquids.** E. M. SALERNI. Brit. 282,493, Sept. 21, 1926. Gas passes through a rotating spiral scroll of sheet metal or the like which may contain contact materials such as Fe filings, turnings or coke.
- Apparatus for gaseous reactions.** HANS HARTER. Fr. 634,582, Dec. 18, 1926. To facilitate the reaction of gases or vapors, rotating paddle wheels or screws are provided for mixing the gases. The vanes of the wheels, etc., may carry catalytic material.
- Preventing leakage of ether or other treating fluids from cyclic treating systems.** JESSE M. COAHN (to Olean Sales Corp.). U. S. 1,680,452, Aug. 14. A system such as an app. using ether to ext. HOAc from pyroligneous acid is vented to the atm. and treating fluid such as ether tending to escape through the vent is absorbed in material to be treated. An app. is described.
- Apparatus for leaching caliche or other materials with circulating liquid in successive stages.** WALTER L. REMICK. U. S. 1,678,787, July 31.
- X-ray tube.** GUSTAV BUCKY. U. S. 1,679,804, Aug. 7. Structural features.
- X-ray tube.** GUSTAV BUCKY. U. S. 1,679,332, July 31. Structural features.
- Röntgen-ray apparatus.** F. S. SMITH. Brit. 282,020, Dec. 8, 1926.
- Röntgen-ray apparatus.** SIEMENS-REINIGER VEIHA GRS. FÜR MEDIZINISCHE TECHNIK. Brit. 282,009, Dec. 8, 1926.
- Luminous discharge tube containing rarefied argon and mercury vapor.** RAYMOND R. MACHLETT (to Rainbow Light, Inc.). U. S. 1,680,271, Aug. 7.
- Luminous tubes.** RAYMOND R. MACHLETT (to Rainbow Light, Inc.). U. S. 1,680,272, Aug. 7. The tubes contain a rare atm. gas such as Ne under reduced pressure and electrodes which may be mainly formed of graphite and which contain occluded alkali metal vapor, e. g., Cs. Cf. C. A. 21, 1035.
- Electric discharge tubes.** SIEMENS-SCHUCKERT WERKE GES. M.B.H. Fr. 634,022, May 7, 1927. The walls of the tube are covered on the parts facing the electrode conductors with a conducting lining joined to the electrode conductors to avoid a discharge on the leads.
- Luminous electric discharge tubes.** F. MEYER, H. JOACHIM and E. GERMER (to Naamloze Vennootschap International Octrooibureau). Brit. 282,064, Dec. 10, 1926. In order that luminous discharge tubes may be operated at ordinary voltages,

they are provided with a highly active cathode which may comprise alk. earth oxide or similar active material. Various structural details are given.

Electronic discharge apparatus. LA RADIOTECHNIQUE. Fr. 634,551, April 21, 1926. A rigid supporting frame for a cathode having several elements in parallel is described.

Bolting machines. CHARLES A. GESNEL. Fr. 634,009, May 7, 1927. The material to be bolted is caused to strike the bolting cloth at an angle which varies according to the degree of fineness required.

Furnaces. GEOFFREY MARTIN. Fr. 634,013, May 7, 1927. In a shaft furnace for lime, gypsum and cement and for calcining ores, a preheating or decarbonating zone and a clinkering zone are provided. The cross-sectional area of the preheating zone is much greater than that of the clinkering zone so that the speed of the ascending gases in the clinkering zone is at least four times that of the gases in the preheating zone.

Thermionic valves. A. JUST (to General Electric Co., Ltd.). Brit. 282,539, Nov. 10, 1926. A thermionic cathode is formed with a metallic core such as W, Mo, Ni, Pt or an alloy, permeated or coated with a mixt. of oxides which may comprise mainly an alk. earth metal oxide together with a smaller proportion of other oxides such as those of Cr, U, Th, Nd, Pr or Sm or La. The oxides may be obtained from the corresponding azides.

Thermionic valves. W. C. SPROESSER (to Westinghouse Lamp Co.). Brit. 281,687 Dec. 1, 1926. An electron-emitting body is formed with a core of metal such as W treated with electron-emitting material such as Th, Zr, U or V. The materials may be heated together in H at 1150° for 1 hr. in an elec. furnace.

Thermostatic controls for electric resistance heaters. IRVIN G. THOMAS (to Westinghouse Elec. & Mfg. Co.). U. S. 1,678,885, July 31.

Thermostatic control system for resistance heaters, etc. ROLLO B. LINCOLN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,678,865, July 31.

Thermostatic device for controlling electric circuits. JOHN L. BROWN. U. S. 1,679,070, July 31.

Thermostatic device for regulating electric circuits. AUGUST J. MOTTLAU (to Westinghouse Elec. & Mfg. Co.). U. S. 1,680,428, Aug. 14.

Thermostatic control for electric switches. JOEL R. COOK (to Westinghouse Elec. & Mfg. Co.). U. S. 1,679,649, Aug. 7.

Thermostatic electric switch. HOWARD D. MATTHEWS (to Westinghouse Elec. & Mfg. Co.). U. S. 1,680,426, Aug. 14.

Thermostatic control and safety device for gas burners. MILEY W. THOMAS and PAUL H. HAMILTON (to Sands Mfg. Co.). U. S. 1,678,658, July 31.

Thermostatic valve for gas water heaters or other apparatus. CLARENCE H. MORROW (to Hotstream Heater Co.). U. S. 1,679,165, July 31.

Bimetallic thermostatic devices. VICTOR G. VAUGHAN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,678,889, July 31. One thermostatic element is formed of Ni steel and the other of an alloy of Co and Fe. Cf. C. A. 22, 2498.

Drying apparatus with air circulation controlled by a thermostat and hygrometer. A. F. WRIGHT. Brit. 281,785, Sept. 14, 1926.

The pressure transitions of the rubidium halides. P. W. BRIDGMAN. Harvard Univ. *Z. Krist.* 67, 363-76(1928).—The transitions which occur at high pressures are not what would be expected, and do not give rise to modifications of the CsCl type. L. S. RAMSDELL

The theory of plastic deformations. FRIEDRICH KÖRBER AND ERICH SEIBEL. *Naturwissenschaften* 16, 408-12(1928).—It is assumed that plastic deformations take place by 2 equiv. systems of slip planes with their axes perpendicular to an external main stress direction and crossed over an angle depending on the av. main stress. Each system consists of 2 perpendicular sets of slip planes at a 45° angle with the external main stress direction. The theory is essentially an elaboration of that of Roß and Eichinger. The slip planes are not crystallographic planes but av. empirical ones. The theory accounts for observations on contraction of stressed flat bands. B. J. C. VAN DER HOEVEN

X-ray investigation of some univalent perchlorates. W. BUSSEM AND K. HERMANN. *Z. Krist.* 67, 405-8(1928).—The perchlorates of NH₄, K, Rb, Cs and Tl form an isomorphous series, and crystallize in orthorhombic bipyramidal class. The unit cell dimensions (*a*, *b* and *c*) are 9.22 Å. U., 5.80, 7.42, 8.85, 5.66, 7.24; 9.27, 5.81, 7.53; 9.82, 6.00, 7.79; and 9.42, 5.88, 7.50, resp. These values agree with the axial ratios, except that the length of *a* is doubled. There are 4 mols. in the unit cells, which belong to space group *V_h¹⁶*, as is usual for compds. of type ABO₄. L. S. RAMSDELL

The crystal structure of the monopropylammonium halides. STERLING B. HENDRICKS. Rockefeller Inst. *Z. Krist.* 67, 465-71(1928); cf. *C. A.* 22, 2861.—The structures of propylammonium chloride, bromide and iodide are detd. by means of Laue and spectrum photographs. There is 1 mol. in the unit cells, which have the following values for *a* and *c*: (Cl) 4.48, 7.40 Å. U.; (Br) 4.57, 7.36; (I) 4.85, 7.33. L. S. RAMSDELL

The crystal structure of the triethylammonium halides. STERLING B. HENDRICKS. Rockefeller Inst. *Z. Krist.* 67, 472-81(1928).—The Et₃NH halides are hexagonal, and belong to space group 6c-4. There are 2 mols. in the unit cells, which have values for *a* and *c* as follows: (Cl) 8.38, 7.08 Å. U.; (Br) 8.56, 7.49; (I) 8.78, 7.74. L. I. R

The crystal structure of bixbyite and artificial manganese oxide. WM. ZACHARIA SEN. Univ. Oslo. *Z. Krist.* 67, 455-64(1928).—The structure of bixbyite is isomor-

phous with that of Mn₂O₃, showing that the formula is (Fe, Mn)₂O₃ rather than FeMnO₃. The space group is *T_h⁶*. There are 16 mols. in the unit cell, which has *a* = 9.35 ± 0.02 Å. U. An analysis of bixbyite is given. L. S. RAMSDELL

X-ray investigation in the system lead-thallium. F. HALLA AND R. STAUFER. *Z.*

Krist. 67, 440–54(1928).—A mixed crystal contg. 35 at. percent Pb and 65 at. percent Tl has a cubic space lattice with $a = 4.871 \pm 0.007$ A. U. The structure is identical with that of Pb, with slightly smaller spacing. There is no evidence of any intermetallic compound, the Tl being in solid soln. in the Pb. A new detn. for Pb gives $a = 4.924 \pm 0.010$ A. U.

L. S. RAMSDELL

Crystal data on cardiazole, pentamethylenaminotetrazole and dilaudid (of the Knoll Co.). H. STEINMETZ. *Z. Krist.* 67, 434–9(1928).—Cardiazole, or pentamethylenetetrazole, is monoclinic prismatic, with $a:b:c = 1.8171:1.15690$, $\beta = 120^\circ 15'$, $n_D = 1.617$. Pentamethylenaminotetrazole is monoclinic, $1.6455:1.24725$, $\beta = 95^\circ 23'$, $n_D = 1.592$ m. 91° . A hydrated form has $a:b:c = 0.5368:1:0.5943$, $\beta = 95^\circ 52'$, m. 58. Dilaudid ($C_{17}H_{15}NO_3$) is orthorhombic, with $a:b:c = 0.75:1:0.49$. L. S. RAMSDELL

Deformation of a single crystal of copper under tensile test. KEIJI YAMAGUCHI. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 327–33(1928); *Abstracts* 1, 29–30.—From measurements of the 3 sides of a triangle drawn on one face of the test piece, the directions of the intersections of this face with the unextended cone were calcd., and since one of these intersections agrees with the direction of the slip-bands appearing on the face, it is concluded that the deformation is of the nature of a shear. The plane of the shear is one of the octahedral planes of the deformed crystal; its direction is one of the diad (110) axes on that face. The deformation occurs in the same manner as that of an Al crystal, which has a like structure.

A. L. HENNE

Molecular structure and the scattering of x-rays. G. W. STEWART AND M. MANNHEIMER. *Z. anorg. allgem. Chem.* 171, 61–72(1928); cf. Stewart and Morrow, *C. A.* 21, 3551.—A bibliography of the scattering of x-rays by non-cryst. substances is given. S. and M. doubt the assumption of crystal structure in liquids because the length of the C chain for liquid $C_{11}H_{23}OH$ calcd. by Sherrer's equation from their data is less than that observed for solid $C_{11}H_{23}OH$ by Bragg's method. The intensity of x-ray scattering of the hydrocarbons from C_4 to C_{12} , of the monobasic fatty acids from C_4 to C_{11} , of the normal primary alcs. from C_4 to C_{11} , and of several isomers is plotted to show the regular change of the curves with the change of chem. structure. MALCOLM DOLE

The active radius of lattice particles in crystals. W. F. DE JONG. *Physica* 8, 129–36(1928).—A table is given with the active radii for some 60 elements in at. or ionic state as detd. by several authors. The different values as derived from various structural types in numerous recently detd. minerals are compared and discussed on the basis of Goldschmidt's hypothesis of ball packing and polarization influences. J. finds, however, the exptl. evidence insufficient for definite support of this theory. It is suggested that an explanation of the interatomic distances on the basis of deBroglie's wave theory may finally appear as definite soln. of the problem. B. J. C. VAN DER HOEVEN

Molecular theoretical basis of the physical properties of crystalline substances. ADOLF SMEKAL. *Z. Ver. deut. Ing.* 72, 667–73(1928).—A discussion of the properties of a substance as related to cryst. structure and the lattice theory, with particular reference to the distinction between the "ideal crystal" and the "real crystal." A photoelec. method of detecting a loosening in the mol. structure of individual crystals is discussed with reference to the relation between such loosening and the properties of the material.

H. STOERTZ

Separation of mixed crystals from solution. G. TAMMANN AND A. YA. ZVORUKIN. *Z. anorg. allgem. Chem.* 173, 73–80(1928).—A discussion of the mechanism of the sepn. of mixed crystals from soln. The sepn. curves are detd. by growth characteristics and the protective action of one salt upon the other rather than by thermodynamic considerations. If the surface of the crystals has a uniformly inoculating action upon the soln., the sepn. curve runs very close to the diagonal of a square, and this is generally the case with salts contg. water. But if the inoculating action is located only at particular spots on the surface of the crystals, as is generally the case with anhyd. salts, then crystals sep. of such compn. as is protected against the action of the soln.; mixed crystals of 0–0.8 mol. of the more difficultly sol. component sep. from solns. with 0–0.8 mol. of the more sol. component, and the sepn. curve is far removed from the diagonal of the square.

H. STOERTZ

The lead tree. V. KOHLSCHÜTTER. *Festschrift A. Tschirch 1926*, 425–30; *Chem. Zentr.* 1927, I, 3178.—A review of the complicated origin of the lead tree, which is formed through interrelated chem. and morphological processes. The sepn. of Pb from the soln. is considered to be an electrochem. phenomenon: $Zn + Pb^{++} \rightarrow Pb + Zn^{++}$, in fact as *electrolytic crystn.* The motive force is a resultant of the soln. pressure of the Zn and the tendency of the Pb to sep., and also depends upon the concn. of both ions in the sphere of action and therefore diminishes with progress of the reaction. The local changes of concn. caused by the sepn. of Pb govern in part the external form of

the Pb tree, while the internal structure depends upon the manner in which the cryst. nuclei develop and the crystals grow. The character of the structure which develops is related to the crystallographic properties of the metal. Moreover secondary chem. reactions between the sepd. metal and dissolved salts and the formation of hydrolytic cleavage products exert an effect on the development of the Pb tree. Difficultly sol. basic salts sep. and the adsorption film and membrane which form change the potential and influence in a purely mech. way the distribution of nuclei and the growth of crystals. The first phenomenon leads to the formation of concd. chains and the so-called "auto-genic Pb tree formation."

C. C. DAVIS

An accurate method for comparing the compressibilities of gases below atmospheric pressure. C. G. ADDINGLEY AND R. WHYTLAW-GRAY. *Trans. Faraday Soc.* 24, 378-87(1928).—A differential app. is described for comparing the compressibilities of gases at pressures lower than 1 atm. in which equal vols. of 2 gases are expanded by known amts. until the pressures are again equal. By a repetition of this process the vols. at a series of equal pressures are compared. Two similar cylindrical volumeters contain the gases confined over Hg with 2 dead spaces forming the upper extremities of a short Hg manometer. The total gas-filled space is equalized on both sides of the manometer to the same pressure, and the Hg is then accurately withdrawn from the volumeters in order to expand the gases until they again exert equal pressures. The advantages of the method and app. are: (1) compactness, rendering accurate temp. control easy; (2) elimination of const. errors; and (3) increased accuracy of vol. measurement. The ratio of the compressibility coeffs. of H_2 and O_2 was found to be: $(1 + \lambda) O_2 / (1 + \lambda) H_2 = 1.00148$.

J. H. PERRY

Mutual attraction and repulsion of gas molecules and their relation to the theory of internal friction. LEON SCHAMES. *Physik. Z.* 29, 91-4(1928).—Mathematical. The potential energy (ϕ), between 2 mols., represented by the equation: $\phi = -(A/r^m) + (B/r^n)$ for the attractive and repulsive forces, resp., gives, for He, the values $m = 8$ and $n = 8$.

J. H. PERRY

The influence of glass upon vapor pressure. JACOBUS RINSE. *J. Chem. Soc.* 1928, 1442-9.—A detn. of the vapor pressure of HgI_2 showed a continuous passage from the satn. curve to the Gay-Lussac line similar to that previously found by McHaffie and Lenher (*C. A.* 19, 3188; 20, 3367; 21, 1576) for water and benzene. The deficiencies in vapor pressure were much greater with HgI_2 . The effect is independent of the degree of dryness and of the smoothness of the glass receptacle, and is augmented by the presence of glass powder. No reaction between glass and HgI_2 could be detected. If the phenomenon is one of adsorption, the layers would have to be 500 mols. thick, which is regarded as improbable.

C. H. GREENAWALT

Composition of vapors from boiling binary solutions. D. F. OTTHER, Eastman Kodak Co. *Ind. Eng. Chem.* 20, 743-6(1928).—A new app. is described for detn. of the relation between vapor and liquid compn. in boiling binary solns. New data are given for mixts. of H_2O and $AcOH$, C_6H_6 and $AcOH$, HCl and H_2O and Me_2CO and $MeOH$.

T. S. CARSWELL

The separation of constant-boiling mixtures; a problem for students of physical chemistry. ARTHUR A. SUNGER. *J. Chem. Education* 5, 879-81, 884(1928). Suppose a fair quantity of a const.-boiling mixt. must be sepd. into its components, pure A and pure B, what general phys. methods are available to accomplish this? Student answers include the following: (1) gaseous diffusion, since from the general gas equation $pV = \frac{1}{2} nmu^2 = RT$, and at const. temp. for 2 kinds of mols. the speeds of the mols. will vary inversely with the square roots of their mol. wts.; (2) non-equil. evapn., since $m_1/m_2 = p_1/p_2 \sqrt{M_1/M_2}$, and therefore with unequal vapor pressure sepn. ought to be possible; (3) thermal diffusion; (4) change vapor pressure of the soln. by addn. of a liquid or solid solute, as illustrated by certain methods for prep. abs. EtOH from the 95% grade; (5) change the pressure to something other than normal and then distil since the vapor pressure relations under the new conditions will not be the same as they were for the const.-boiling mixt.; (6) f. p. alterations—in reality an application of vapor pressure relations. A problem like the above stimulates thought on the student's part, particularly as not much can be found in the literature bearing on the subject.

W. C. EBAUGH

The vapor pressures of binary systems. II. Gold and mercury. ALFRED W. PORTER. *Trans. Faraday Soc.* 24, 405-7(1928); cf. *C. A.* 22, 3075.—An expression $\log(a_1/a_2) = \beta\mu_2^2/(1 + \rho\mu_2)^2$ has been fitted to exptl. detns. of the vapor pressure of Au in Hg. As this equation is of a form forbidden by Margules' equation, important properties of the mixt. are not brought out and the following equation is offered: $\log a_1 = a \log \mu_1 + \beta\mu_2^2 + \gamma\mu_2^3(4 - 3\mu_2)$. This satisfies the exptl. data under certain con-

ditions. The curve obtained from the data is discussed. III. Calcium chloride and water. *Ibid* 407-8.—From the data obtained by Harrison and Perman of vapor pressures of water in equil with sols. of CaCl_2 it has been found impossible to fit the exptl. values to the equation above except by employing 4 terms. Equations for 80° and 40° are given and the curves for these are drawn and discussed. Since at least 4 terms are necessary with substances like CaCl_2 it is not surprising that so little success has been achieved in the past in obtaining formulas for satn. G. H. W. LUCAS

New azeotropes. I and III. MAURICE LECAT. *Ann. soc. sci. Bruxelles* 45, 169-76, 284-94 (1926); *Chem. Zentr.* 1927, I, 2282-3; cf. *C. A.* 21, 1583, 2834.—Seventy-five binary systems were studied to det. whether const.-boiling, homogeneous mixts. (azeotropes) were formed. Glycol (b. 197.4°) showed a surprising behavior, for it gives in part heterogeneous const.-boiling mixts. with considerable lowering of the b. p., and in part homogeneous const.-boiling mixts., a behavior which is attributed to the mol. assocn. of the glycol. Azeotropes with increased b. ps. are comparatively rare. The following data show the b. ps. of the individual compds. used and the b. ps. of their mixts.: 22% CHBrCl_2 (90.2°) + trichloroethylene (86.95°), 86.7° ; 46% BzOMe (199.5°) + Et malonate (198.9°), 198.2° ; 40% glycol (197.5°) + linalool (198.7°), 182.2° ; 36.5% glycol + PhCH_2OH (205.1°), 193.1° ; 53.5% glycol + *p*-cresol (201.6°), 195.2° ; 46% glycol + guaiacol (205.1°), 190.4° ; 15% glycol + pentachloroethane (161.95°), 154.5° (heterogeneous); 25% glycol + *o*- $\text{BrC}_6\text{H}_4\text{Me}$ (181.75°), 166.8° (heterogeneous); 51% glycol + C_{10}H_8 (218.05°), 183.9° (heterogeneous); 20% glycol + camphene (159.5°), 152.5° (heterogeneous); 59% glycol + PhNO_2 (210.85°), 185.9° ; 24% glycol + PhNH_2 (184.35°), 180.55° ; 15% glycol + cineole (176.4°), 164.75° (heterogeneous); 28% cineole + PhOH (182.2°), 182.85° ; 57% cineole + AcOEt (180.4°), 168.8° ; 9.3% α -pinene (155.8°) + MeOH (64.7°), 64.55° ; (α -pinene with EtOH shows contrary to Maumené (*Compt. rend.* 57, 955 (1863) no azeotropy); 22% α -pinene + *iso*- AmOH (130.8°), 129.1° ; 25% α -pinene + CHBr_3 (149.3°), 146.5° ; 62% α -pinene + furfural (161.4°), 143.4° ; 63.5% α -pinene + α , α -dichlorohydrin (175.1°), 150.4° ; 50.2% α , α -dichlorohydrin + Et lactate (153.9°), 143.1° ; 56% C_{10}H_8 (218.05°) + $\text{PhCH}_2\text{CH}_2\text{OH}$ (219.5°), 214.2° ; 45% C_{10}H_8 + terpineol (217.8°), 212° (C_{10}H_8 shows no azeotropy with Me salicylate or $\text{ClCH}_2\text{CO}_2\text{H}$); Me salicylate (222.3°) shows no azeotropy with PhNO_2 or with safrol; 71% Me salicylate + AcNH_2 (220.9°), 205.8° ; 37% Me salicylate + terpineol (217.8°), 216.0° ; 43.5% camphene + cyclohexanone (155.6°), 150.7° ; 44% camphene + PhBr (156.15°), 155.0° ; 59% camphene + cyclohexanol (168.7°), 151.9° ; 45% camphene + Et lactate (153.9°), 144.95° ; 58% camphene + Me oxalate (163.5°), 146.65° (sep. at 62.6°); 60% camphene + furfural (161.4°), 146.75° (sep. at 48°); cyclohexanol + 55% furfural (161.4°), 155.55° ; C_6H_6 gives with CHBrCl_2 and with chloral no azeotropy; 20.5% EtOH + PrBr (71.0°), 62.75° ; 55% *iso*- AmOH (130.8°) + CHBr_3 , 129.9° ; 65% *iso*- AmOH + paraldehyde (124.0°), 122.9° ; 17% *n*-octyl alc. (195.15°) + PrNH_2 (184.35°), 183.95° ; 97% AcMe (56.3°) + PrBr , 56.15° ; 5% AcOEt + *iso*- Am butyrate (178.6°), 173.2° ; 73% tetrachloroethane (146.25°) + $\text{ClCH}_2\text{CO}_2\text{Et}$ (143.6°), 147.45° ; chloral (97.75°) + 40% *iso*- Bu formate (146.25°), 147.45° ; chloral + 49.5% AcOPr (101.6°), 102.55° ; pyrrole (129.2°) + 51% Et_2CO_3 (125.9°), 131.0° ; pyrrole + 67% ethylene bromide (131.45°), 131.0° ; 39.5% CH_3NO_2 (101.15°) + methylcyclohexane (100.95°), 81.25° (heterogeneous); 18% *iso*- AmI (147.65°) + *iso*- Am acetate (142.1°), 141.7° (cf. Holley, *J. Am. Chem. Soc.* 24, 448, the data of H. are incorrect for *iso*- AmOH - CHBr_3 as well). PrNH_2 b. 221.9° and not 213° as usually recorded. In the original are the temp. increases of mixts. and curves of the crit. soln. temps. of the system: MeOH - α -pinene. The earlier expts. were continued with 150 more systems. Amides readily give azeotropes with large depression of the b. p. Systems with lowered b. p. (A temp. marked ξ refers to the temp. of sepn.).—24% AcNH_2 (220.2°) + PhNEt_3 (217.05°), 198.05° , ξ 179° ; 27.2% AcNH_2 + C_{10}H_8 (218.05°), 199.5° , ξ 148.05° ; 16% AcNH_2 + carvene (177.8°), 169.2° (heterogeneous); 36% AcNH_2 + pulegone (224°), 205.9° , ξ 65.9° ; 16.3% AcNH_2 + acetophenone (202.5°), 197.45° , ξ 36.8° ; 28% AcNH_2 + α -terpineol (217.8°), 205.2° , ξ 46° ; 77% AcNH_2 + PhNO_2 (210.75°), 201.65° , ξ 54.6° ; 31.5% PrNH_2 (222.1°) + C_{10}H_8 , 204.65° , ξ 75.0° ; menthol gives with C_{10}H_8 , PhNO_2 , Me salicylate and $\text{PhCH}_2\text{CH}_2\text{OH}$ azeotropes with slight depression of the b. p.: 70% camphene (159.6°) + AcOEt (180.4°), 156.15° ; 87% camphene + PhNH_2 (184.35°), 157.5° , ξ approx. 30° ; 74% camphene + Et malonate (181.4°), 154.6° , ξ 55.4° ; 52% Et malonate + carvene (177.8°), 167.3° ; 78% Et malonate + α -pinene (155.8°), 151.5° ; 56% glycol + α -terpineol (217.8°), 189.55° ; 69% glycol + $\text{PhCH}_2\text{CH}_2\text{OH}$ (210.4°), 194.4° ; 67.5% glycol + geraniol (229.7°), 194.65° ; 54.2% glycol + borneol (213.2°), 198.25° , ξ 99° ; 47.5% carvene (177.8°) + methylheptenone (173.2°), 170.9° ; 72% PhNO_2 + tetra-

pineol (217.8°), 209.5°; 22% PhNO₂ + citronellal (207.8°), 206.8°; 56% PhCH₂OH (205.15°) + citronellal, 202.9°; 75% PhCH₂OH + *p*-IC₆H₄Me (213°), 203°; 12% PhCH₂OH + perchloroethane (185°), 182.0°; PhCH₂OH + 12% PhNH₂ (184.35°), 176.75°, ξ 101°; PhCH₂OH + 49.5% AcOEt (180.4°), 172.5°, ξ 86°; 25% PhCH₂OH + ClCH₂CO₂H (189.35°), 171.2°; 24.5% ClCH₂CO₂H + *p*-C₆H₄Cl₂ (174.1°), 167.55°; 56% *iso*-AmOAc (142.1°) + Me lactate (143.8°), b. 138.5°, 47% ClCH₂CO₂Et (143.0°) + Pr butyrate (142.8°), 141.7°; 66% *n*-heptane (98.45°) + Me butyrate (102.65°), 94.9°. Systems with increased b. ps.—40% Cl₂CCHCl₂ (161.95°) + mesitylene (164.6°), 166.0°; *p*-ClC₆H₄OH (219.75°) + Et succinate (217.25°), 231.8° (the compn. was uncertain); *p*-ClC₆H₄OH + 45% AcOCH₂Ph (214.9°), 226.5°; *p*-ClC₆H₄OH + 72% bornyl acetate (227.7°), 232.7°; *p*-ClC₆H₄OH + 50.2% α -terpineol (217.4°), 225.7°; *p*-ClC₆H₄OH + 42.5% menthol (216.4°), 223.5°; *p*-ClC₆H₄OH + 47.5% borneol (213.2°), 222.5°; *p*-ClC₆H₄OH + 8% PhNO₂ (210.75°), 219.9°; 62.5% thymol (232.8°) + PhCH₂CO₂Et (228.75°), 235.75°; 60% thymol + bornyl acetate (227.7°), 235.6°; 55% thymol + PhCO₂Pr (230.9°), 235.5°; 57.5% thymol + geraniol (239.6°), 235.6°; 60% thymol + *n*-decanol (232.5°), 234.5°; 52% thymol + carvone (230.95°), 238.55°. Non-azeotropic systems are also listed, which in part can be classified on a basis of their isobars. IV. *Ibid* 47, 21-7.—The expts. continued with an investigation of 104 more systems. Noteworthy in particular was the large depression of the b. p. of systems contg. glycol. With glycerol, 2 azeotropes with esters and 4 eutectics with hydrocarbons and ethers were observed. As in the preceding work, the following data represent only the more important compds.: 52% glycol (197.4°) + acetophenone (202.05°), 185.65°; 22.5% glycol + methylheptenone (173.2°), 168.1°; 9% glycol + (CHCl₃)₂ (146.35°), 145.05°; 7% glycerol (290°) + PhCH₂CO₂Et (228.75°), 228.6°; 10% glycerol + bornyl acetate (227.7°), 226.0°; 75% PhCH₂Cl (179.3°) + ClCH₂CO₂H (189.35°), 173.8°; azeotropism with *iso*-Am butyrate was doubtful, and with ClCH₂CO₂H there was a reaction at the b. p.; approx. 35% chloropicrin (111.85°) + EtOH (78.3°), 77.4°; 33.5% chloropicrin + *iso*-PrOH (82.45°), 82.0°; 58.5% chloropicrin + PrOH (97.2°), 94.0°; 67.5% chloropicrin + *iso*-BuOH (107.85°), 102.05°; 61% Et borate (118.6°) + Et butyrate (120.0°), 117.55°; Et borate forms other azeotropes with *iso*-BuOAc, *iso*-AmBr, chloroacetone. 71.5% PhMe (110.75°) + chloroacetone (119.7°), 109.2°; 22% PhOH (182.2°) + camphene (159.6°), 156.1°; approx. 1.8% ClCH₂CO₂H (189.35°) + (CHCl₃)₂ (146.35°), 146.25°; 9.9% ClCH₂CO₂H + Cl₂CCHCl₂ (161.95°), 158.65°; 78% ClCH₂CO₂H + C₁₀H₈ (218.05°), 187.1°; 39.5% *p*-BrC₆H₄Me (185°) + (CCl₄)₂ (185°), approx. 183.5°; 63.5% PhCO₂Me (199.45°) + glycol (197.4°), 182.2°; 39% cyclohexanone (155.6°) + trichlorohydrin (156.85°), 160.0°; 55% cyclohexanone + (CHCl₃)₂, 159.1°; 32% *iso*-AmOAc (142.1°) + (CHCl₃)₂, 150.1°; Approx. 13% PhOH (182.2°) + 1-octanol (195.15°), 1195.4°; 71% PhOH + pinacene (174.35°), 185.5°. Change of the surface tension of mercury by the addition of small quantities of alkali and alkaline-earth metals. FRANZ OPPENHEIMER. Frankfurt-A.-M. *Z. anorg. allgem. Chem.* 171, 98-101 (1928).—O's. work is in conjunction with that of Fraenkel and his co-workers on reaction velocities between 2 liquid phases (*C. A.* 18, 1774; 22, 3334). The capillary-height method of measuring surface tension was employed with the use of a perfectly transparent quartz app. The amalgams were prep'd. free from oxide with difficulty, but suitable materials were finally procured by electrolysis of highly viscous salt-paste electrolytes, with a Hg cathode; they were purified by filtration *in vacuo*. While only relative values were sought, the surface tension of Hg was det'd. as 437 dynes/cm.; this may be offered as a standard of comparison. Amalgams of Ca, Li and Na in varying concns. were measured and found to have tensions lower than that of Hg. A table is given. The surface tension of bromoform is raised by the addn. of diazo-acetic ester.

Observations on the state equation of the adsorbed phase. II. BUN-ICHI TAMAMUSHI. *Bull. Chem. Soc. Japan* 3, 142-6 (1928), cf. *C. A.* 22, 706.—The following data refer to butyric, valeric, caproic, caprylic, capric and lauric acids, resp.: i (Rideal equation) = 0.73, 0.63, 0.43, 0.40, 0.35, 0.23; η = 1- i : 0.27, 0.37, 0.57, 0.54, 0.65, 0.77; P , in dynes/cm. = 10.6 31.4, 11.0 33.6, 9.2 34.3, 11.0 27.0, 14.9-24.7, 10.2-19.8; r = $\sqrt{A/N}$, where A is calcd. from P , and $P, A/RT$ or directly measured, and N is the Avogadro no. 6.5×10^{-8} , 6.0×10^{-8} , 5.6×10^{-8} , 5.5×10^{-8} , 5.5×10^{-8} , 5.5×10^{-8} ; μ in electrostatic units $\times 10^{-18}$ = 17, 18, 20, 19, 21, 22.

A. L. HENNE

The density of anhydrous chromic chloride and adsorption of water vapor from the atmosphere by the same. M. CRESPI. *Anales soc. españ. fis. quim.* 26, 152-63 (1928).—CrCl₃ adsorbs H₂O vapor, which causes a variable d. of the product. The adsorption is analogous to that of gases on glass walls, according to the equation $dx/dt = 1/(at + b)$.

The amt. of H_2O adsorbed exceeds 0.5 mol. of H_2O per mol. of $CrCl_3$, and mol. vol. increases with increase in H_2O adsorbed. $CrCl_3$ must be heated above 100° in a current of dry air to become dehydrated. Under such conditions it has a d. of 2.916. R. M. S.

Influence of viscosity on the rate of absorption of carbon dioxide by solutions of neutral sodium carbonate. PAUL RIOU AND PAUL CARTIER. *Compt. rend.* 186, 1727-6 (1928); cf. C. A. 22, 3079.—A previous report covers the effects of glycerol, dextrose and sucrose on the rate of absorption of CO_2 in solns. of neutral Na_2CO_3 (C. A. 21, 1576). Tabulated results are now given for the effects produced by the addn. of various concns. of ethylene glycol, levulose, MeOH, EtOH, HCHO and lactose. Taken in connection with the previous results R. and C. conclude that: (1) While viscosity has some influence on the rate of absorption of a gas by a liquid, it is in no case the principal factor involved. (2) The chem. function of the added org. crystalloid plays a very important, if not the preponderant, role in influencing the rate of absorption. (3) Org. crystalloids, not producing combinations with neutral Na_2CO_3 , increase the rate of absorption even though they increase the viscosity. MeCHO at a concn. of 0.0037 g. per 100 cc. of soln. increases the rate from 43.4 to 50. At a concn. of 0.3 g. the rate is increased to about 130. These results suggest catalytic action and might lead to interesting industrial applications in the washing of gas. This is to be investigated further. W. W. S.

The liquid-crystal state as a general property of material. VI. The liquid-crystal state of natural silk. P. P. VON VEIMARN. *Kolloid-Z.* 45, 161-2 (1928).

J. H. PERRY

The change of the hydrogen-ion concentration of stable kaolin suspensions due to mechanical agitation in capillary tubes. ALICE JEPPESEN. *Kolloid-Z.* 45, 156-8 (1928).—The decrease in the pH of kaolin suspensions with time is attributed to an increase of the adsorbing surface.

J. H. PERRY

The velocity of sedimentation of nickel hydroxide. HITOSI TOMINAGA. *Bull. Inst. Phys. Chem. Research (Tokyo)* 7, 298-301 (1928); *Abstracts* 1, 26-7.—The velocity of sedimentation of $Ni(OH)_2$ in various concns. depends on the concn. In contradiction with Perrin's experiments on gamboge, it is necessary to take the concn. into account to deduce the sizes of the particles from the sedimentation velocity. The sizes of the particles directly measured with a microscope are in good agreement with those deduced from the sedimentation velocities.

A. L. HENNE

Interpretation of the analysis of a hydrosol of arsenic trisulfide. VITTORIO GAZZI. *Zymologica chim. colloidi* 2, 10-2; *Chem. Zentr.* 1927, II, 27; cf. C. A. 22, 525.—In an analysis by Murphy and Matthews (cf. C. A. 17, 928) of a colloidal As_2S_3 , calcn. of the trisulfide from the total S minus the S in the H_2S gave smaller values than that calcd. from the As content of the $Mg_3As_2O_7$ ppt. From this M. and M. advance the hypothesis that a complex compd. of the As_2O_3 (As_2S_3)_n type exists in the soln. Contrary to this, G. maintains that a mixt. rather than a complex is present, because (1) when the II is expelled on prolonged heating, the ratio of the quantity of decompd. trisulfide to the total quantity slowly increases, and (2) As_2O_3 can be sepd. from the hydrosol by dialysis and ultra-filtration. The calcns. and the preps. of M. and M. are included.

C. C. DAVIS

Some properties of silicic acid gels. PAUL BARY. *Rev. gén. colloides* 6, 85-9 (1928); cf. C. A. 22, 2003.—Silicic acid gels prepd. by adding acid to solns. of Na_2SiO_3 in a tube coated with vaseline form hard transparent cylinders. When such silicic acid gels are dried in air until the H_2O content is between 27.2 and 35.1%, the gel is pulverized when thrown into water, slightly acidulated water, or ether. The density of the powder is 1.722. For a sample whose compn is SiO_2 1.5 H_2O , a reasonable distribution would be SiO_2 , 69%; combined H_2O , 20.7%, free H_2O , 10.3%; space filled by air 6%. When liquids whose surface tension is strong surround such a gel, the pressure exerted by the air compressed in the capillaries is sufficient to pulverize it.

F. E. BROWN

Stability of dispersoid systems. F. N. GAPON. *Ukrainskii Khim. Zhurnal* 3, No. 1, sci. pt., 133-7 (1928).—Continuing the researches of P. P. von Veimarn (cf. "Grundzüge der Dispersoidchemie," 1911) G arrives at the following conclusions: The life (he uses the expression duration of existence) Z of the dispersoid system, the concentration C (expressed in the number of mols. per unit of volume) of the dispersoid phase and the degree of activity S of the medium are bound up thus: $ZC = S$. The dispersoid systems $CuCl_2 \cdot 2H_2O$ formed by passing dry HCl into a soln. of copper oleate in moist C_6H_6 possesses an equal degree of dispersion. In the reaction $Cu_2H_2O_4 + 2HCl$ the increase of moisture decreases the stability of the dispersoid systems. In the reaction $Cu_2H_2O_4 + 12HCl$ $Z \times C$ is const., which proves that the degree of activity of the medium remains const.

BERNARD NELSON

The viscosity of gelatin solutions containing alcohol. A. JANEK AND BR. JIRGENSONS. Univ. Riga. *Lettlånd. pharmaceut. J.* 1927, No. 2, 7 pp.; *Chem. Zentr.* 1927, I, 2050.—With the aid of the Ostwald viscometer, the viscosities of 0.5% gelatin solns. contg. the same no. of mols. and then the same no. of cc. of water, MeOH, EtOH and PrOH were measured at 25°. The tables and graphs show that alcs. increase the viscosity of gelatin soln., this ability increasing with the mol. wt., thus: water < MeOH < EtOH < PrOH. The viscosities increased with the time of standing, most rapidly with MeOH and less rapidly with EtOH and least rapidly with PrOH. In the expts. with the same vols. of alcs. the viscosity curves intersected after a certain time, followed by a reversion of the series so that the gelatin soln. contg. MeOH became more viscous than those contg. PrOH, EtOH or water. C. C. DAVIS

The Hofmeister ionic series in the precipitation of the hydrophylic colloids. KUNIO ANDO. *Nagoya J. Med. Sci.* 2, 110-23(1927).—J. Loeb (cf. *C. A.* 17, 2590) stated that the Hofmeister series does not exist, when the p_H is exactly measured. K. checked this statement by examg. the pptn. of colloidal hemoglobin and egg-white solns. by various ions under proper consideration of the p_H . He concluded from his expts. that in the pptn. of the hydrophylic colloids the Hofmeister series is still valid except with the buffer salts (acetate, citrate, tartrate). Pptn. according to the valency also occurs, and it increases directly, the more distant the p_H is from the isoelec. point. Pptn. of the hydrophylic colloids is synchronous discharge and dehydration of the micelles. In the isoelec. point the hydrophylic colloids have a min. of stability against EtOH. On both sides of the isoelec. point there is an abrupt increase of sensitiveness to salts. G. SCHWACH

Application of the Donnan theory to the adsorption of ions by colloidal silicic acid. P. B. GANGULY AND SUBRAMONIA KRISHNAMURTI. *Trans. Faraday Soc.* 24, 401-5 (1928).—The adsorption of ions from HCl by particles of colloidal silicic acid prepared by different methods has been measured by application of the Donnan theory of semi-permeable membranes. The methods of prepn. were: Graham's method (hydrolysis of Me silicate), hydrolysis of $SiCl_4$, and hydrolysis of SiS_2 . The amt. of ion adsorbed generally increased with the activity of the acid from which the ion was adsorbed. The colloid prepd. from $SiCl_4$ showed a preferential adsorption for Cl ions, while that from Me silicate had a preference for H ions. The diffusibility of the colloid from Me silicate through collodion membrane was small as compared with that from $SiCl_4$. While the diffusibility of the colloid does not change regularly with the strength of the acid outside the membrane, the general conclusion that diffusibility increases as the strength of the acid increases, is justified. J. H. PERRY

Polychroism and orientation of ions in crystals of the rare earths. R. BRUNETTI. *Physik. Z.* 29, 571-5(1928).—See *C. A.* 22, 2311. E. H.

Projection of Brownian movement. N. HENRY BLACK. *J. Chem. Education* 5, 868-73(1928).—An app. is built up on an optical bench as follows: A 90° arc light from cored carbons, an aplanatic condenser of about 5 cm. focal length with an iris diaphragm, a water cell about 5 cm. thick with parallel sides, a double convex lens of about 20 cm. focal length, and then a perforated screen. On the end of the optical bench is placed a compound microscope on a stand, so as to be in the usual vertical position, and at such a height that the center of its mirror is exactly on the optical axis of the projection app. A "Kardiod Kondensor" (not a paraboloid dark-field condenser) is inserted under the stage, and on the stage is a fused quartz plate (Zeiss) made for this kind of work. A drop of rutile suspension is put on the plate, then a thin glass cover. A $1\frac{1}{2}$ -in. oil-immersion objective with an iris diaphragm (Zeiss 90 N. A. 1.25) and a low-power (Zeiss No. 1) objective are used. Above the microscope a 45° glass prism is employed to throw the image upon a vertical screen, a large piece of white cardboard. In a darkened room the movements of the rutile particles can be seen well by a class of 75 to 100. Following the above demonstration, B. uses a mechanical model (Pohl, of Göttingen) with lantern projection to show how the relatively large colloidal particles are made to move by collision with rapidly moving mols., larger wooden balls and tiny steel balls simulating the colloid particles and mols. respect. W. C. F.

Dimensional studies of colloids. Nobel-prize addresses. The heterogeneity of colloidal solutions and sedimentation in a centrifugal field. THE SVEDBERG. *Sep.* 14 pages.—A description is given of the various centrifuges designed and built under the direction of the author. Rate of sedimentation and the sedimentation equil. may be used independently for obtaining the mol. wt. of a substance. Tables are shown for data on hemoglobin. The two methods give good agreement. Data on equil. are also given for egg albumin both salt-free and in one percent NaCl. Many uses for this method of study are suggested. A study of the ultramicroscope and description of col-

loidal solution. RICHARD ZSIGMONDY. 12 pages.—The progress of visible studies of colloids and the development of the ultramicroscope are related. Studies of gold hydrosols in a Tyndall bean are described together with observed relations between the electric charge and coagulation. Photographs of gel structure of gelatin and soaps are given. The motion of a particle under an elec. current, the structure of particles, and their relative dimensions with respect to the mol. are reviewed. The results obtained with the ultramicroscope have important bearings on the mol. structure of matter.

R. H. LAMBERT

The theory of electrodialysis. RICHARD BRADFIELD. *Naturwissenschaften* 16, 404-8(1928).—Electrodialysis of colloids with two pos. or two neg. diaphragms tends to give alk. or acid reaction of the liquor dialyzed in the middle chamber. The exptl. Pauli cell consisted of 2 110-cc. chambers, sepd. by 25-sq. cm. diaphragms at a distance of 6 cm. The anode membrane was collodion treated for 40 hrs. with a 2% hemoglobin soln., and the cathode membrane was parchment. The hemoglobin membrane is positive (isoelec. point 6.8) in weakly acid solns. The results of the expts. on ion migration are given in tables; it is concluded that anions and cations are removed in practically equiv. amts., since little change in the p_H of the middle space was found. The resistance of the hemoglobin membrane is larger than that of parchment or collodion alone. The electro-dialytic activity of the system, as measured by $E = (\text{acid} + \text{base removed}) / \text{no. coulombs}$, is high, however, and the anion seems to penetrate the membrane easily. For 0.025 *N* salt solns., electrolyzed at 120 v. for 20 mins., E for NaCl is 0.71; for salts of weak acids (phosphate, acetate) it increases to 1.37 and 1.32. This rather abnormal behavior is explained by electroosmotic transport of liquid contg. undissoed. acid and is promoted by high local concn. of the latter. The hemoglobin diaphragm is always positive regardless of the reaction of the middle chamber as confirmed from expts. with agar gels contg. methyl red. It is caused by high anion concn. on both sides of the anode membrane. In the case of weak acids this effect may even lead to pptn. of slightly sol. acid (e. g., benzoic) and it will induce the transport of considerable undissoed. acid across the diaphragm. The opposite effect also exists: from Mg salt solns. $\text{Mg}(\text{OH})_2$ could be made to ppt. near the cathode membrane.

B. J. C. VAN DER HOEVEN

The decomposition velocity of tribromoacetic acid in water. OSC. DE GROOTE. Ghent Univ. *Bull. soc. chim. Belg.* 37, 225-39(1928).—The decompn. products of aq. $\text{CBr}_3\text{CO}_2\text{H}$ are exclusively CHBr_3 and CO_2 . Tables and charts record the velocity of the reaction. It is concluded that the reaction is unimol. and that only the $\text{CBr}_3\text{CO}_2^-$ ion controls it.

A. L. HENNE

The dilution and neutral-salt errors of buffer mixtures. CHARLES MORTON. *J. Chem. Soc.* 1928, 1401-13.—The properties of the following mixts. were studied: (1) $1/2$ neutralized solns. acetic and cacodylic acids; (2) $1/4$ neutralized solns. of aspartic acid and arginine; (3) $3/4$ neutralized solns. of *o*-phthalic and α -monoglycerolphosphoric acids; (4) mixts. of $\text{Na}_2\text{P}_2\text{O}_7$ and HCl in the mol. proportions of (a) 2.3, (b) 2.1. For these mixts., resp., (1) $p_H = p_K$, (2) $p_H = p_{K_1}$, (3) $p_H = p_{K_1}$, (4a) $p_H = p_{K_1}$, (4b) $p_H = p_{K_2}$, where $K = 10^{-p_K}$ is the apparent dissoen. const. of the buffer electrolyte. To these solns. various amts. of KCl, NaCl, K_2SO_4 , BaCl₂, and MgSO_4 were added and the p_H (or p_K) change produced by each addn. was noted. The effect of diln. was also studied. In all cases p_K decreased on the addn. of neutral salts but increased with diln., both effects becoming more pronounced with increase in valence of the buffer acid. When the concn. of added salt is small, the p_H change is independent of the sp. nature of the salt, depending only on the valence type; with larger addns. a sp. salt action is exhibited. As regards the importance of their effects in producing p_H changes in acid buffer mixts., the influence of the neutral salts is in the order $\text{BaCl}_2 > \text{MgSO}_4 > \text{NaCl} > \text{KCl} > \text{K}_2\text{SO}_4$ whatever the nature of the buffer acid. For basic buffers the order is reversed; $\text{K}_2\text{SO}_4 > \text{KCl} > \text{NaCl}$. In dil. soln. the p_K or p_H changes produced by further diln. or by the addn. of small amts. of neutral salts were described by the equation $p_K = p_H + \log (\text{acid})/(\text{salt}) + A\sqrt{\mu}$, within the p_H limits of 4 to 10, where μ is the ionic strength and p_K and A are true constns. In solns. of higher ionic strength, the H-ion relationships were defined by the equation $p_K = p_H + \log (\text{acid})/(\text{salt}) + A\sqrt{\mu} - B\mu$, where B is a coeff. expressing the sp. action of the ions. The value of A for an *n*-valent buffer mixt. is approx. ($n - 0.5$). The buffer unit of Van Slyke (*C. A.* 16, 2097) is not a complete criterion of buffer efficiency. It is suggested that this value should be supplemented by the unit $\pi = dp_H/d\sqrt{\mu}$ expressing the diln. and neutral salt errors. The limiting diln. error is independent of the strength and sp. nature of the buffer electrolyte, depending only on the valence type. For a monobasic buffer

mixt. the limiting diln. error is $\pi = -0.5$, that of an n -valent mixt. is approx. $(2n - 1)$. The thermodynamic disson. consts. of aspartic (K_{A1}), acetic, cacodylic, pyrophosphoric (K_3 , K_4), o -phthalic (K_2) and α -glyceryl-phosphoric (K_2) acids and of arginine (K_{B1}) were detd. to be, resp., $K_{A1} = 1.27 \times 10^{-4}$, $K = 1.84 \times 10^{-5}$, $K = 5.60 \times 10^{-7}$, $K_3 = 1.98 \times 10^{-7}$, $K_4 = 1.32 \times 10^{-10}$, $K_2 = 4.65 \times 10^{-6}$, $K_2 = 1.80 \times 10^{-7}$, $K_{B1} = 6.64 \times 10^{-6}$.

EDGAR R. SMITH

Bromophosgene. I. Thermal decomposition—a first-order wall reaction. SAM LENHER AND HANS-JOACHIM SCHUMACHER. Univ. Berlin. *Z. physik. Chem.* **135**, 85–101(1928).—The equil. $\text{CO} + \text{Br}_2 \rightleftharpoons \text{COBr}_2$ is established very slowly in the dark at room temp.; the yield of COBr_2 is less than 10%. The light stationary state, on the other hand, is reached in a few hours. For Br_2 at 200 mm. and CO at 500 mm. the yield of COBr_2 at equil. is 10%. The thermal decompn. is a first-order wall reaction, independent of added gases, but dependent on the character of the wall, being most rapid in quartz, second in borosilicate glass, and slowest in sodium glass. The temp. coeff. in borosilicate glass between 210° and 230° is 1.8 per 10° increase. C. H. G.

The oxidation of ferrous hydroxide in sodium hydroxide solution by means of air. SUSUMU MIYAMOTO. *Bull. Chem. Soc. Japan* **3**, 137–41(1928); cf. *C. A.* **21**, 1744.—The rate of the oxidation of FeO with air is independent of the amt. of FeO present. The values of the velocity consts. are almost the same as in the case of the oxidation of Na_2SO_3 or SnO under the same conditions. The effect of the temp. is small. NaOH decreases the velocity of the oxidation. The mechanism of this reaction is to be explained by considering that the oxidation velocity thus measured is no other than the solution velocity of O , and that NaOH decreases the solution velocity of O in the soln.

A. L. HENNE

A further study of the reaction between nitrogen dioxide and liquid mercury. WILLIS C. PIERCE and W. ALBERT NOYES, JR. *J. Am. Chem. Soc.* **50**, 2179–87(1928).—The rate of reaction between Hg and NO_2 as measured by the time of formation of a uniform visible film is dependent, among other things, on the shape of the reaction vessel. The times tend to become shorter the longer the reaction vessel is used. There are variable factors which have not been entirely detd. The reaction is accelerated by the presence of large nos. of ions. Positive and negative ions, as far as can be detd., have equal effects. The action of light in accelerating the reaction is most probably to be ascribed to the activation of a surface film. This seems in some way to be associated with the photoelec. effect. Acceleration of the dark reaction with continued use of the vessel may be due to the contamination of the surface by minute crystals swept in by the NO_2 . This acceleration may obscure the action of the light. E. R. S.

Mechanism of the saponification of cellulose esters of higher fatty acids. ICHIRO SAKURADA. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) No. 132, **8**, 21–41(1928). (In Esperanto, with German summary.)—The tri-, di-, mono- and lower esters of *stearic acid*, prepd. from cotton paper and $\text{C}_{17}\text{H}_{35}\text{COCl}$, were sapon. with alc. KOH by a bimol. reaction which indicates a series of steps: triester \rightarrow diester \rightarrow monoester \rightarrow regenerated cellulose. If this heterogeneous reaction is expressed simply as $dx/dt = ks(a - x)$, in which s is the contact surface of ester with KOH soln., we have: $s = k(b - x)$; i. e., at each instant the contact surface of ester with KOH soln. is in direct ratio to the concn. of the latter. Shaking 150 times per min. increases the rate of sapon. about 50%. The effect of temp. from 0° to 38.5° follows the Arrhenius equation $\log k = -(A/T) + C$. Diln. of the KOH soln. with H_2O reduces the sapon. velocity very greatly ($\log k = mC + n$, where C = concn. of alc.); the retarding effect of neutral salt is not important.

AUSTIN M. PATTERSON

Saponification of cellulose acetate by alkali. ICHIRO SAKURADA. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) No. 133, **8**, 42–53(1928). (In Esperanto, with German summary.)—Sapon. of acetone-sol acetate with aq. caustic alkali without shaking follows, up to about 50%, the equation: $dx/dt = k(a - x)$, where a is the original concn. of alkali, and x the amt. changed after time t . Above 50% the rate suddenly drops. With shaking the above equation holds to 90%. If the heterogeneous sapon. is expressed by: $dx/dt = k's(a - x)$, where s is the contact surface of ester with alkali soln., then during the reaction s must be a const. (why, is still unexplained). Sapon. with KOH in various strengths of alc., without shaking, proceeds rather rapidly at first and then slows up markedly. Without shaking, sapon. with KOH in fairly strong alc. follows the equation: $dx/dt = k(a - x)(b - x)$, where a and b are the original concns. of alkali and ester and x is the amt. changed after time t . A test for quality of acetylcelluloses is proposed, based on a comparison of sapon. velocities.

AUSTIN M. PATTERSON

Saponification of cellulose acetate during hydration. ICHIRO SAKURADA. *Sci.*

Papers Inst. Phys. Chem. Research (Tokyo) No. 134, 8, 54-61(1928). (In Esperanto, with German summary.)—The sapon. which occurs in prepg. acetone-sol. acetylcellulose by hydration of acetone-insol. primary triacetylcellulose with AcOH, H₂O and H₂SO₄ shows the same mechanism as sapon. with alkali (see the 2 preceding absts.). Assuming that the amt. of H₂O remains unchanged in sapon., the sapon. velocity as a whole may be expressed as: $dx/dt = k(b - x)$. The sapon. during ripening at various temps., when calcd. on this assumption, agrees fairly well with exptl. results obtained earlier in the same lab. The reaction velocities of tri-, di-, and mono-acetylcellulose are, resp., $dx_1/dt = 3k(b - x_1)$, $dx_2/dt = 2k(x_1 - x_2)$, and $dx_3/dt = k(x_2 - x_3)$, where b is the initial concn. and x_1 , x_2 and x_3 are the changed amts. of tri-, di- and monoester. The concn. is expressed in no. of g. mols. of C₆ unit in unit vol. The concns. of the different esters after a certain time interval are: $C_{tri} = be^{-3kt}$, $C_{di} = 3b(1 - e^{-kt})$, $C_m = 3b(1 - e^{-kt})e^{-kt}$, $C_{cat} = b(1 - e^{-kt})^2$. The values calcd. on this basis and on the assumption that monoester and regenerated cellulose are acetone-insol. agree with those obtained in practice by Hess *et al.* in the prepn. of acetone-sol. ester by sapon. of tri-Ac ester.

AUSTIN M. PATTERSON

Reactions in liquid hydrogen sulfide. IV. Thiohydrolysis of esters. A. W. RALSTON AND JOHN A. WILKINSON. *J. Am. Chem. Soc.* 50, 2160-2(1928); cf. C. A. 22, 1519.—The thiohydrolysis in liquid H₂S of Me, Et, Pr, iso-Pr and Bu thioacetates was calcd. from cond. measurements at various concns. The calcd. degree of thiohydrolysis increases with the mol. wt. of the ester and is larger than the degree of hydrolysis of esters of similar O acids in water at room temp. The results are tabulated.

E. R. SMITH

Studies on autocatalysis in the formation and reduction of cuprous oxide. J. OKAYAMA. *Z. Elektrochem.* 34, 294-8(1928).—The possible explanation of catalysis in the copper oxidation and copper oxide reduction are discussed. The autocatalytic course of the copper oxidation is established, and that of the reduction of copper oxide confirmed. In studies on the reduction of copper oxide, consideration must be given to the adsorption of the water vapor formed.

M. FENSKE

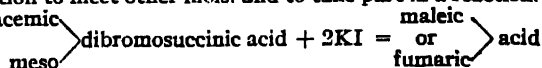

A study of auto-ignition temperatures. II. Pure compounds. HENRY J. MASSON AND WILLIAM F. HAMILTON. *Ind. Eng. Chem.* 20, 813-6(1928); cf. C. A. 22, 706.—The auto-ignition temps. of an addnl. no. of pure org. compds. have been detd. in air at ordinary pressures. The compds. selected cover a wide range of properties and structures in order to provide data for use in studying various combustion reactions. A study has also been made of the catalytic effect of various surfaces on auto-ignition temps.

G. CALINGAERT

The mechanism of catalytic hydrogenation in the cold. A note. M. BOURGUEL. *Bull. soc. chim.* 43, 231(1928); cf. C. A. 22, 2099.—A typographical error in the previous paper caused omission of names from the curves on page 1447. Curve 1 shows the complete reduction of cyclohexylpropine and curve 2 that of tolane. Reported lack of success in prepg. colloidal Pd according to the directions given in the previous paper is probably due to the use of rice starch instead of potato starch.

R. L. DODGE

Heterogeneous catalysis and adsorption. II. C. F. VAN DUIN. *Rec. trav. chim.* 47, 715-36(1928).—The acceleration of the reaction between α , β -dibromopropionic acid and inorg. iodides by the addn. of carbon, previously found by Kruyt and van Duin, was confirmed. An acceleration occurs with the Na salt as well as with the acid itself. The sapon. of Me *m*- and *o*-sulfobenzoates, Me isovalerate, monoacetin, mono-Me succinate, mono-Me *d*-tartrate, and di-Me *meso*-tartrate and the inversion of sucrose were investigated and it was shown that the addn. of carbon retards the reaction in all cases. Even in the most favorable case, the sapon. of di-Me *meso*-tartrate, the acceleration of the reaction, due to the undoubtedly favorable orientation of the adsorbed mols., is insufficient to overcome the decrease of the velocity of the reaction in consequence of the less favorable condition of adsorbed mols. to take part in a reaction, caused by the adsorption itself. The unimol. reaction, racemic dibromosuccinic acid \rightarrow bromofumaric acid + HBr, was shown to be retarded by the addn. of carbon. This supports the Kruyt and van Duin first hypothesis, that adsorbed mols. are in a less favorable condition to meet other mols. and to take part in a reaction. The velocity of both reactions: racemic

+ 2KBr + I₂ was shown to be greatly increased by the addn. of carbon, the acceleration being much greater than with the α , β -dibromopropionic acid and its Na salt. This supports the second hypothesis, that adsorption can cause positive catalysis only in the case where the orientation of the adsorbed mols. is such that the reacting groups

are turned away from the adsorbent and towards the surrounding liquid. This orientation must be such a favorable one that the primary decrease of the reaction velocity, caused by the adsorption itself, is overcome. The sapon. of mono-Me *d*-tartrate and di-Me *meso*-tartrate by means of an alk. SnO_2 suspension was investigated, in the former case a decrease of the reaction velocity being found and in the latter case the same velocity as in the absence of the colloidal SnO_2 . This result is explicable in only one way, that with mono-Me *d*-tartrate the orientation of the adsorbed mols. is less favorable than with di-Me *meso*-tartrate. With mono-Me *d*-tartrate the retarding influence due to adsorption itself preponderates, while with di-Me *meso*-tartrate this retarding influence is just compensated by the accelerating influence due to the favorable orientation of the adsorbed mols.

M. FENSKÉ

The decomposition of hydrogen peroxide on glass powder in presence of salts. WINIFRED M. WRIGHT. *Z. Elektrochem.* 34, 298-300(1928).—The decompn. of H_2O_2 in aq. soln. on glass powder is in agreement with the results of Elissaffoff (*C. A.* 9, 3015) in that it is considerably accelerated by metallic salts. AgNO_3 , CuSO_4 and $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$ are especially active. HgCl_2 retards the decompn. in presence of the glass powder. The decompn. velocity of H_2O_2 was measured in the presence of glass powder and different concns. of AgNO_3 at 0° . The reaction was approx. monomol., the const. decreasing somewhat with time. The adsorption of Ag^+ in AgNO_3 soln. on glass powder follows the ordinary adsorption isotherm. The decompn. velocity of H_2O_2 in presence of glass wool and AgNO_3 is about proportional to the amt. of Ag^+ which under the same conditions is adsorbed on the glass powder.

M. FENSKÉ

Silver-ion catalysis of persulfate oxidations. III. The oxidation of ammonium ion. CECIL V. KING. *J. Am. Chem. Soc.* 50, 2080-8(1928); cf. *C. A.* 22, 1521. —This reaction, previously studied by Marshall (*Proc. Roy. Soc. Edinburgh* 23, 163(1900)) and others, has been reinvestigated in more dil. solns. by the cond. method. Recent work of Yost suggests that Ag^+ ion is oxidized to Ag^{++} by the persulfate ion and is, in turn, reduced by the NH_4^+ to Ag^+ , at an immeasurably rapid rate. In the present work, the autocatalytic character of the curves shows that the reduction of Ag^{++} to Ag^+ is not immeasurably rapid in lower concns. (0.0005 *M* $(\text{NH}_4)_2\text{S}_2\text{O}_8$ and 0.0005 *M* AgNO_3) and that some small concn. of Ag^{+++} is built up in the soln. The mechanism of cane sugar inversion and of ester hydrolysis is discussed in the light of the present work. IV. Oxidation of oxalate ion. *Ibid.* 2089-99. —The rate of oxidation of oxalate ion by persulfate ion, in dil. aq. soln., has been measured. With no catalyst, the reaction is very slow. When Ag salts are added, the reaction is more rapid than similar oxidations of NH_4^+ , NH_4^+ , and Cr^{+++} . This difference in reaction rate is probably due to some peculiarity in the reaction itself, although vessel walls and accidental impurities are thought to have some catalytic effects. Some curves of autocatalytic type are shown. The intermediate compd. formed is not thought to be the Ag^{+++} ion postulated in the other oxidations (cf. above). The velocity of reaction is very irregular which makes it difficult to explain the mechanism of the reaction.

A. J. CURRIER

Heating powdered substances below their melting points and eutectic temperatures. BERNWARD GARRE. *Zement* 17, 446-8(1928).—The reactivity of powd. solids on heating below their m. p. or eutectic temps. is aided by compacting into pellets or by mixing with liquids, especially those liquids in which one or both solids are sol. H. F. K.

The eutectic in binary systems. F. KORDS. Kaiser Wilhelm Inst. Silikatforschung Berlin-Dahlem. *Metallhose* 17, 481-2, 541; *Chem. Zentr.* 1927, II, 8, cf. *C. A.* 21, 3010; 22, 530, 2106. —New equations are given for calcg. the eutectic temp. and the compn. of the eutectic mixt. from the f. ps. of the pure components. The depression of the eutectic point increases in systems with components of similar character in the following order: mol. compds. < ternary electrolytes < binary electrolytes < elements. A study of the influence of assocn. of pure compds. which takes place during fusion showed in systems with 2 binary electrolytes for the eutectic point depression the following order: neither component associated < both components associated < only 1 component assocd., while the f. p. depression diminishes up to the beginning of crystn. in dil. solns. because of assocn.

C. C. DAVIS

The system alumina-water. GUSTAV F. HÜTTIG AND EBERHARD VON WITTEGENSTEIN. Deut. tech. Hochschule, Prag. *Z. anorg. allgem. Chem.* 171, 323-43(1928). —The same method and app. have been used for the system $\text{Al}_2\text{O}_3\text{-H}_2\text{O}$ as in previous investigations (cf. *C. A.* 15, 2597; 16, 3280; 17, 2542). The following points are examd.: colloid system $\text{Al}_2\text{O}_3\text{-H}_2\text{O}$; transformation of an amorphous colloid system into a macroscopic cryst. system; hydrargillite and its dehydration products; products obtained by the aging of the colloid system $\text{Al}_2\text{O}_3\text{-H}_2\text{O}$; diasporé and its dehydration products;

effect of high temps. and high water-vapor pressure; activity of Al_2O_3 and $\text{Al}(\text{OH})_3$.

A. L. HENNE

The quaternary system: $\text{Na}_2\text{O}-\text{Na}_2\text{O}_2-\text{H}_2\text{Cl}_2-\text{H}_2\text{O}$. V. I. NIKOLAEV. *J. Russ. Phys.-Chem. Soc.* 59, 289-98(1927).—In the system: $\text{NaCl}-\text{NaNO}_3-\text{K}_2\text{O}$, the effect of the addn. of NaOH , or a mixt. of HCl and HNO_3 on the soly. of the two salts was studied at 15° , 25° and 35° . Measurements were made of the soly. of NaCl in presence of increasing quantities of NaNO_3 in neutral soln. A thermostat was used accurate to $0.1-0.2^\circ$. Equil. was reached in 8-96 hrs. (the latter in the case of some alk. solns.). The vessel contg. the solns. was sealed with Hg. Soly. tables are given. The quaternary system is represented by a tetrahedron. The mutual crystn. lines of NaCl and NaNO_3 located inside the tetrahedron meet at the eutonic point of max. salt content corresponding to a neutral soln. of min. vapor pressure. The soly. isotherms of NaCl and NaNO_3 are found on the surface triangles of the figure. The crystn. fields of NaCl and NaNO_3 extend from the resp. isotherms towards the mutual soly. line and each is divided (like the latter) into an alk. and an acid portion. If the variations of a 3-component system with temp. are represented by a triangular prism with the altitude serving as the axis of temps, the behavior of a quaternary system can be similarly plotted by placing a no. of its plane projections above each other at distances proportional to the temp. intervals. The quant. relationship between the elements of tri- and quadri-dimensional space is confirmed, points becoming lines, lines surfaces, and surfaces vols. of identical character.

BASIL C. SOYENKOFF

Representing a four-component system with a parallelogram. SPINDEL. *Tonind.-Ztg.* 51, 1239-41(1927).—In most phys.-chem. research only two- or three-component systems are studied; these can easily be represented with biaxial or triaxial diagrams. In *ceramic research*, however, the no. of components is usually more than 3; an attempt was made to represent a four-component system with a parallelogram. H. G. S.

The measurement of high temperatures in a carbon resistance furnace. W. MEHR, H. IMMKE AND J. KRATZERT. *Tonind.-Ztg.* 51, 1063-8(1927).—Sighting on the specimen through the top with an optical thermometer and inserting the thermocouple in the side was found to be better practice than sighting at the specimen through the side with the optical thermometer and inserting the thermocouple through the top.

H. G. SCHURECHT

The transition temperature of carbon tetrachloride as a fixed point in thermometry. JAMES C. McCULLOUGH AND HARRIS E. PHIPPS. *J. Am. Chem. Soc.* 50, 2213-6(1928).— CCl_4 when cooled below its f. p., has a reversible, solid-solid transition from the cubic to the monoclinic system at $-48.4 \pm 0.02^\circ$. Since the f. p. is generally regarded as a fixed thermometric point the use of pure CCl_4 will therefore also serve as a second fixed point.

J. H. PERRY

The measurement of high temperature by means of a tungsten-molybdenum thermocouple. D. BINNIE. *Roy. Tech. Coll. Met. Club J.* 1927-8, No. 6, 35-6.—A W-Mo thermocouple was used to measure temps. up to 1700° . The couple was formed by twisting the end of a 0.4-mm. W wire around the end of a 0.635-mm. Mo wire and pressing them tightly together with pliers. The thermoelec. curves for various W-Mo couples, in all cases, follow very closely the graph of a simple mathematical expression of the type $y = cx^n$, where c is a const. and n is a power approx. equal to 2. At a temp. of 1500° the power is 7 to 8 microvolts per degree, and at 1600° 8 to 9 microvolts per degree.

DOWNES SCHAAF

The specific heat and chemical constant of cadmium. FRITZ LANGE AND FRANZ SIMON. *Z. physik. Chem.* 134, 374-80(1928).—The sp. heat of a sample of Cd, proved by x-rays to contain only the ordinary hexagonal form, was measured from 10 to 50° A. U. From the formula for vapor pressure $\log_{10} p = -5819.4/T - 1.2572 \log_{10} T + 12.287$, the chem. const. is +1.57. The theory for at. gases gives 1.49. F. R. B.

The specific heat of nickel above the Curie point. PIERRE WEISS. *Compt. rend.* 187, 12-4(1928).—A theoretical discussion is given of recent data on the sp. heat of Ni. Above the Curie point the at. heat shows the same gradual increase with temp. as the at. heat of Cu. Their difference is const. and equal, within the precision of the measurements, to the part of the at. heat 0.993 corresponding to the kinetic energy of one degree of freedom.

W. W. STIFLER

Atomic number and heat of formation. W. A. ROTH AND O. SCHWARTZ. *Z. physik. Chem.* 134, 456-66(1928).—If the heats of formation of oxides and chlorides of metals of the same group are plotted against at. no. smooth curves are obtained. These curves have 2 branches, for the A and B group, which intersect at the common element. It is possible to interpolate for unknown heats of formation. To check this interpolation the heat of hydrolysis of $\text{SiCl}_4(\text{liq}) + 2\text{H}_2\text{O}(\text{liq}) + \text{aq.} = \text{SiO}_2(\text{gel})$

+4HCl(aq) was measured and found to be 70.1 ± 0.15 kg. cal. The heat of hydrolysis of GeCl_4 to form GeO_2 (solid) is 25.0 cal. F. R. BICHOWSKY

The heat of formation of water-alcohol mixtures partially miscible. PIERRE BRUN. *Compt. rend.* 186, 1729-31(1928).—The heats produced by mixing various proportions of H_2O , EtOH and iso-AmOH were measured calorimetrically by the classical Berthelot method. The results are presented in a tri-linear coordinate diagram. For ternary as for binary mixts. mixing involving a contraction is exothermic, and endothermic when expansion is involved. In either case $\Delta q = f\Delta V$. Also Biron's relation for sp. heats of binary mixts. is applicable to these ternary mixts. provided the 2 alcs. have approx. the same sp. heat. W. W. STIFLER

The heat capacity of hydrogen bromide from 15°K. to its boiling point, and its heat of vaporization. The entropy from spectroscopic data. W. F. GIAUQUE AND R. WIEBE. *J. Am. Chem. Soc.* 50, 2193-2202(1928).—HBr prepd. directly from the elements was used to det. the heat capacity and heat of vaporization. Three max. in the curve of heat capacity and temp. indicate gradual transitions of the type noticed with NH_4Cl by previous workers. The heat of fusion was 575.1 cal. per mole and the m. p. was $186.24 \pm 0.05^\circ \text{ abs.}$ The b. p. was $206.38 \pm 0.05^\circ \text{ abs.}$ The heat of vaporization at 760 mm. was 4210 ± 4 cal. per mole, and the entropy at the b. p. was 44.9 ± 0.1 entropy units. The entropy of HBr calcd. from spectroscopic data was 47.53 e. u. with the Tetrode const. at 298.1° abs. and 44.92 at $206.38^\circ \text{ abs.}$ J. H. PERRY

The heat capacity and entropy of cesium alum from 18° to 300° absolute. The entropy of aluminum ion. The potential of the aluminum electrode from thermal data. WENDELL M. LATIMER AND BERNARD S. GREENSFELDER. *J. Am. Chem. Soc.* 50, 2202-13(1928).—A detailed description is given of a vacuum calorimeter for measuring the heat capacity of solids from the triple point of H_2 to room temp. The heat capacity of $\text{CsAl}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ was detd. for the temp. range 18.7° - 297.8° abs. , and the entropy at 298.1° abs. was found by plotting C_p vs. $\log T$ and multiplying the area under the curve by 2.3026. The value is 163.85 entropy units. The f.-p. lowerings of dil. solns. of Cs and Rb alums were measured on nearly satd. solns. which were gradually dild. over the desired range. The activity coeffs for these alums were then calcd. from the f.-p. lowerings. The heat of soln. of Cs alum was $+13,560 \pm 25$ cal./mole at 298.1° abs. The entropy of soln. of Cs alum is $+2.18$ e. u., and the entropy of Al^{+++} at 298.1° abs. in a hypothetical one-molal soln. is -70.9 cal./deg./mole. The potential of the Al electrode is $+1.69$ v. J. H. PERRY

Molecular heat and entropy of hydrochloric acid calculated from band spectra data. ELMER HUTCHINSON. *J. Am. Chem. Soc.* 50, 1895-1900(1928).—The mol. heat of gaseous HCl is computed from band spectra data for temps. from 1° K. to 600° K. A max. in the mol. heat vs. temp. curve occurs at 12.5° K. At 0° the mol. heat obtained from band spectra data agrees very well with the exptly. detd. value. The method of Giauque and Wiebe was used to calc. the entropy at different temps. The molal entropy of HCl at 0° is 44.04 or 43.72 entropy units, depending on whether the Tetrode or the Lewis value of the chem. const. is used. M. FENSKE

Molecular pressure and latent heat of vaporization of liquids. K. STAKHORSKI. *Inst. angew. Chem. Charkov. J. Russ. Phys. Chem. Soc.* 58, 966-82(1926); *Chem. Zentr.* 1927, 1, 2043; cf. *C. A.* 20, 2769; 21, 3780.—The internal pressure B is calcd. by the following equations: $B = 41.35 l/v$, where l is the heat of vaporization per g., and v is the sp. vol.; $B = 1149 T/M$, where T is abs. temp. and M is the mol. wt. of the liquid; $B = 1.5a_c(22400)^2/(Mv)^2$, where a_c is the van der Waals const. a at the crit. temp.; and $B = 80p_c$, where p_c is the crit. pressure. The numerical consts. of the last 3 equations apply to $T = 0.5 T_c$ and give B in atms. With the aid of the B values obtained in this way, the validity of the following empirical relations is proved: $B = 235.9 \gamma T/T_c$, where γ is the surface tension; $B = \alpha T/\beta$, where α is the expansion coeff. and β the compressibility coeff. at low pressure (cf. Jäger, *Die Fortschritte der Kinet. Gastheorie*, 1906); $l = \alpha v T/41.35 \beta$ (cf. Lewis, *Z. phys. Chem.* 78, 24); $lT_c = 6.29 T_c \gamma v$; $\beta = 0.00392 \alpha T_c/\gamma$; $\gamma M v = 10.06 (T_c - T)$; $\beta = 2373/[M v (T_c - T)/T_c]$, and $M l = 57.39 (T - T_c)/T_c$. C. C. DAVIS

The dissociation of ammonium chloride vapor. H. BRAUNE AND S. KNOKE. *Z. physik. Chem.* 135, 49-62(1928).—Vapor density measurements on NH_4Cl showed complete disson. in the range 250 - 390° and 16 - 820 mm. Hg. The accuracy of the measurements is 0.1%. The heat of vaporization is given as 39.4 kg. cal/mol. at 320° and the sublimation temperature -340.3° . Values of $\log p$ plotted against $1/T$ show a linear function. C. H. G.

Thermodynamic properties of oxygen and nitrogen. RUSSEL W. MILLAR AND

JOHN D. SULLIVAN. *Bur. Mines Tech. Paper No. 424*, 20 pp.(1928).—Calcs. have been made on existing data of O and N up to 60 atms. pressure and from 80° to 300° K. The vol., heat content and entropy have been evaluated and are given in tabular form. Two large Mollier charts, one for each gas, accompany the article and are of great value for extrapolating or interpolating. The method of creating the charts is explained, together with the thermodynamic treatment involved. A good list of references is given. R. H. LAMBERT

Normal potential of the iodine-iodide electrode. GRINNELL JONES AND B. B. KAPLAN. *J. Am. Chem. Soc.* 50, 2066-76(1928).—The normal potential of the I-iodide electrode is redetd. against both the Hg_2Cl_2 and H electrodes, by using solns. of such dilns. that the effect of tri-iodide formation is minimized. In the calcs. the concn. of the ions is detd. from the activity coeff. and this is detd. by measurement of the potential of iodide concn. cells with transference contg. Ag-AgI electrodes. The normal potential of the I-iodide electrode against the Hg_2Cl_2 electrode is -0.2544 v. at 25° and -0.2522 v. at 0°, and against the H electrode -0.5362 v. at 25°. H. STOERTZ

The determination of the ζ -potential on cellulose—a method. D. R. BRIGGS. *J. Phys. Chem.* 32, 641-75(1928).—There is an excellent discussion of *electrokinetic phenomena*. The app. used to measure the potential for sulfite pulp and for S. & S. paper was based on the streaming-potential method. The diaphragm of cellulose must be tightly packed to prevent decrease in vol. under increased pressures. H/P (H is streaming potential, P is hydrostatic pressure) is not const. for diaphragms of the same material with different pore dimensions. The failure of H/P to be const. is ascribed to the increased cond. of the fluid in the presence of cellulose. When the correct cond. is used, the value $H\kappa/P$ is const. (κ is the cond. of the fluid in the presence of the diaphragm). The ζ -potentials for two S. & S. papers and a sulfite pulp (ash 0.02%) are 0.0214, 0.0161, and 0.0083 v., resp. The potential depends on the origin and history of the cellulose. The effects of La, Al, H, Mg and K ions were studied. ARTHUR FLEISCHER

Electric conductivity of silicon. H. J. SEEMANN. *Physik. Z.* 28, 765-6(1927).—The sp. elec. resistance of metals increases nearly in proportion to the abs. temp. In contrast to this Si, Ti and Zr are regarded as variable or semi-conductors. C as graphite is no longer considered a semi-conductor, since it has been shown by Ryschkewitsch (cf. *C. A.* 18, 2273, 3515) that single crystals of graphite show a positive temp. coeff. of elec. resistance. S. found the same conditions with Si, although no quant. accuracy could be obtained. Therefore Si is not to be regarded as a semi-conductor. The negative temp. coeff. of polycryst. Si is no doubt caused by insulating superficial oxide layers. It is probable that the same holds for single crystals of Ti and Zr, the oxides of which are good insulators which are likely to cover the true nature of elec. cond. in the polycryst. state. **Supplement.** *Ibid* 29, 94-5(1928).—The analysis of Si used above revealed the presence of Al, Fe, Zn, SiO_2 and traces of C and Mn. It is impossible for the present to indicate the influence of these impurities upon the temp. coeff. of the elec. resistance of pure Si. It appears from the work of Seemann, Clausen (cf. *C. A.* 19, 1513) and others that elements, hitherto regarded as semi-conductors (e. g., Si, Ti, Zr, Th, Hf) show the same behavior as the conductors proper. EMIL KLARMANN

The conductivities of sodium and potassium derivatives of β -ketonic compounds in alcoholic solution. EILEEN WHITE. *J. Chem. Soc.* 1928, 1413-5.—The mol. conductivities of the Na and K derivs. of Et acetoacetate, acetylacetone, benzoylacetone, Et isobutyl and iso-Am acetoacetate and of Na and K ethoxides and KI were detd. in alc. soln. at 25° and dilns. of from 4 to 1024 l. The expts. show that these substances are conductors in alc. soln. and have mol. conductivities only slightly less than that of KI. Dissoen. is not complete at the max. dilns. used. The results are tabulated. EDGAR R. SMITH

The dielectric constant of aqueous solutions of some amino acids. GUNNAR HEDESTRAND. *Inst. allgem. organ. Chemie Univ. Stockholm. Z. physik. Chem.* 135, 36-48(1928).—A modification of the Nernst bridge method was used to det. the dielec. consts. of aq. solns. of amino acids. Glycocoll, α -alanine, β -alanine and taurine increase the dielec. const. of water by an amt. which is linearly proportional to the molar concn. The dielec. consts. of solns. of the aminobenzoic acids decrease very slightly with increase in concn. Neutral salts decrease the dielec. consts. of pure water and glycocoll soln. to a like extent. C. H. GREENEWALT

The dielectric constant of benzil. L. SAINTE-ANTOINE. *Compt. rend.* 186, 1429-31(1928).—S. measures $K = (\lambda^1/\lambda)^2$, where λ is the wave length of the resonator in air (here 235 cm.), and λ^1 is the wave length in molten benzil or a benzene soln. of benzil. For a soln. contg. 10.6 g. of benzil and 100 cc. C_6H_6 , temp., 5, 15, 35°; λ^1 in cm., 424.4, 422.4, 418.2; K , 3.37, 3.34, 3.28; d , 0.920, 0.911, 0.895; $(n-1)/d$, 0.909, 0.908, 0.905.

For 20 g., in 100 cc., temp., 5, 15, 35°; λ^1 471.6, 469.4, 464.8; K, 4.17, 4.13, 4.05; d , 0.943, 0.932, 0.920; $(n-1)/d$, 1.103, 1.107, 1.100. For molten benzil: temp., 95, 110, 120°; λ^1 , 834.2, 818.1, 804.3; K, 13.04, 12.54, 12.12; d ., 1.095, 1.087, 1.077; $(n-1)/d$, 2.387, 2.337, 2.304. The results given by Malleman (*C. A.* 22, 1092), are correct.

A. L. HENNE

Dielectric polarization of liquids. I. Dielectric constants and densities of solutions of the chlorobenzenes in benzene and in hexane. C. P. SMYTH, S. O. MORGAN AND J. C. BOYCE. *J. Am. Chem. Soc.* 50, 1536-46(1928); cf. *C. A.* 18, 3498; 19, 2429.—The dielec. consts. of solns. of C_6H_5Cl and of o -, m -, and p - $C_6H_4Cl_2$ in benzene and in hexane, resp., were measured at 0°, 25° and 50°. These data together with the ds. at the temps. given were used for the calcn. of the polarization of the mixts. and the elec. moments of the mols. **II. Temperature dependence of the polarization in certain liquid mixtures.** C. P. SMYTH AND S. O. MORGAN. *Ibid* 1547-60.—Since the results of part I showed that the effect of polar compds. upon one another in dil soln varied both with temp. and concn. S and M. detd the dielec. consts. of solns. of EtBr, $CHCl_3$ and C_6H_5Cl in hexane over the whole range of temps. and concns. within which the solns. are liquid (approx. -90° to +60°). Mol. polarizations were computed and plotted against mol. fractions for different temps. The values obtained were used (1) to est. approx. values for the polarization due to the shifts of atoms and groups of atoms within the mol.; (2) to get accurate values for the elec. moments of the mols; and (3) to establish the validity of the Debye equation as applied to infinitely dil. solns. The mols. affect one another the more strongly, the greater their moments, the greater their concns. and the lower the temp.

H. S. v. KLOOSTER

Experimental and theoretical study of the variation of the dielectric constant of some liquids with the pressure. L. CAGNIARD. *Ann. phys.* 9, 460-553(1928); cf. *C. A.* 21, 526.—The first part of this monograph is a discussion of methods of measurement. To study the variation of the dielec. const. with pressure below 20 atm. requires a method of measuring capacity capable of detecting a change of 1 part in 1,000,000. The discrepancies between results given by different observers sometimes amount to 20%, though the methods used are said to be accurate to 1% or even 0.1%. C. ascribes these differences to the use of vacuum tubes as amplifiers in the measuring circuit. His method, to avoid these errors, consists essentially of a Wheatstone bridge network with 4 condensers of identical construction, forming the four arms. Two of the condensers are filled with the liquid under test and in one of these the liquid can be subjected to pressures up to approx. 20 atm. The bridge is balanced by an accurately calibrated variable condenser. A quadrant electrometer is used in place of the galvanometer and the sensitiveness is greatly increased by using a resonance method. The bridge is excited by a vacuum tube circuit having a frequency corresponding to a wave length of 6.000 m. Part II starts with a historical summary of previous work followed by details of the technic employed by C. It was found possible to measure not only the rate of change of dielec. const. with pressure at const. temp. (i. e., de/dp) but also the rate of change of this coeff. with temp. (i. e., $d^2e/dp dT$) over a range of 20° to 30°. For 3 of the liquids studied the change in dielec. const. is directly proportional to the pressure, and the curve giving de/dp as a function of temp. is concave upward. For C_6H_6 , $de/dp \times 10^{10}$ varies from 1.25 at 14° to 1.44 at 23.8°; for C_6H_{14} , from 1.55 at 1.1° to 2.10 at 31.7°; for CCl_4 , from 1.61 at 10.8° to 1.91 at 28.6°. Cyclohexane and AmOH present certain anomalies. In part III C. compares his results with those of Ortway. The Mosotti-Clausius, Langevin-Debye, and Gans theories of the dielec. const. are outlined. Both de/dp and $d^2e/dp dT$ show certain important deviations from the theoretical values calcd. by Debye's formula. Apparently if a dipole is present in a mol., the exptl. values of these two coeffs. are less than the theoretical, while the absence of a dipole leads to the opposite result. An attempt is made to interpret the anomalies observed with cyclohexane and AmOH, and the theory of electrostriction in insulating liquids is outlined.

W. W. STIFLER

Apparent changes in the dielectric constant of insulating materials. PAUL BÖNING. *Z. tech. Physik* 9, 212-4(1928).—It has been shown that technical insulating materials have dielec. consts. largely independent of the elec. field (cf. Mattenklodt, *C. A.* 3, 2267). Apparent changes occur however, and are now discussed. It is assumed on the basis of practical evidence that conduction in solid or liquid insulating materials is electrolytic that in boundary planes part of the ions are absorbed (boundary ions) and that in all materials continuous channels filled with electrolyte are present. These assumptions agree with colloidal chem. theories. For the actual dielec. const. ϵ' is derived (electrode distance d const.) $\epsilon' = \epsilon + (A/U)$ for U the potential of the condenser, A a const.; the free ions contribute a flux βd to the dielec. flux $4\pi Q$. For U from

50 to 900 v. this equation represents data (ϵ' from 5.6 to 2.64) of Hoer on paper insulation. If a variable β is introduced the agreement is still better: $\epsilon' = \epsilon + (A/U) - (A/U)\epsilon^{-\gamma}$ for U from 1 to 900 v., $\epsilon = 2.4$, $A = 200$, $\gamma = 0.0663$. Because of time lag ϵ will appear smaller for sudden potential peaks. For const. U and variable d changes in ϵ' will follow from $\epsilon' = \epsilon + Bd^2$.

B. J. C. VAN DER HOEVEN

The dispersion of the conductivity and the dielectric constant of strong electrolytes. P. DEBYE AND H. FALKENHAGEN. *Physik. Z.* 29, 401-26(1928); cf. *C. A.* 22, 2705.—This theoretical paper is a continuation of D. and E.'s study of the irreversible processes of elec. cond. They find 2 essential quantities, the thickness of the ionic atm. and its relaxation time (the time necessary for its formation or its disappearance). If the time of an oscillation of the ion is equal to or less than the relaxation time, then the unsymmetrical charge distribution can no longer completely form; so that for quite high frequencies or high field strengths the mol. cond. rises and approaches the value at infinite diln. This dispersion effect whose existence has hitherto been unsuspected provides the possibility of eliminating experimentally the Coulomb attracting forces between the ions, and a new method of estg. the true degree of dissocn. appears. The general theory of this dispersion phenomenon which takes into account the Brownian movement is given for the case of the dil. soln., and the influence of concn., temp., mobility of the ion, dielec. const and valence on it are calcd. and plotted. M. D.

Study and theory of pyroelectricity. A. MEISSNER AND R. BECKMANN. *Z. tech. Physik* 9, 175-86(1928).—Plates of tourmaline and of quartz $10 \times 10 \times 3$ mm., cut perpendicularly to an elec. axis, were heated on a hot plate from 20° to 300° . One electrode on top of the plate was connected to a string electrometer (Tegetmeyer). On heating, a negative electric moment appears on the side of the plate which has a positive piezoelec. effect; the value of it is const. and depends on the temp. On cooling down after moderate heating the moment goes through zero to positive values that disappear very slowly in the cold. The moment for tourmaline is 1.18 electrostatic units per degree per sq. cm.; for quartz 1.44×10^{-3} electrostatic units per degree per sq. cm. Individual variations of 1:30 occur. There is also an increased cond. effect, i. e., internal compensation of the dipole distortion by freely moving charges. As a result for quartz the negative moment for higher temps. disappears quickly with time but is followed after cooling by a considerable positive moment from which it takes days to recover. From earlier work (piezoelectricity, high-frequency vibrations, cf. Meissner, *Physik. Z.* 28, 621(1927)) has been deduced an almost cubical structure of the Si in quartz with the optical axis following the cube diagonal, the O atoms being paired on the sides of each Si. From a hexagon projection of this Si cube the piezo and pyro effects are schematically explained on the assumption that for the latter Si^{+++} shifts more than the 2O^{--} ions but less than twice as much. An equation relating the pyro effect to temp. and pressure is given.

The electric resistance of copper. A. BROIDO. *Z. tech. Physik* 9, 194-7(1928).—A review of historical attempts to establish a standard resistance value for Cu. In 1913 was adopted the international standard of 17.24 ohms for a wire 1 km. long and 1 sq. mm. in cross section.

B. J. C. VAN DER HOEVEN

Dispersoelectricity. II. Theoretical considerations. H. G. BOS. *Chem. Weekblad* 25, 259-63(1928); cf. *C. A.* 22, 1527.—The total elec. charging effect of a jet of liquid fog is considered to be due (1) to q_1 , the primary charge formed per sec. on the insulated disperser independent of the potentials of surrounding objects (due partly to shear of the electric double layer solid-liquid, partly to liquid and gas flow in the tubes leading to the disperser); (2) q_2 , the electricity leaving the disperser per sec. by ion-conduction, due to potential differences ($V + E$) between it and the surrounding walls: $q_2 = k(V + E)$; (3) q_3 the electricity loss of the disperser for zero dispersion pressures: $q_3 = KV + L$ for V the potential of the disperser tube, K cond. of the gas. Assuming $dV/dt = (q_1 - q_2 - q_3)/C$ for C the capacity of the dispersing system it follows that

$$V_t = (q_1 - kE - L)/(k + K) \left(1 - e^{-\frac{(k+K)t}{C}} \right) + V_\infty e^{-\frac{(k+K)t}{C}}$$
 and the optimum value Δ ("dispersel") for $t = \text{infinity}$ of V is $\Delta = (q_1 - kE - L)/(k + K)$. The leakage $(kE + L)$ can be found from blanks; K and k are preferably small and to be found from

$$e^{-\frac{(k+K)t}{C}} = \sqrt{\frac{\Delta - V_t}{\Delta - V_0}}$$
 thus yielding a value for the primary effect q_1 . In the app. used and described V_0 , E , K and L (hot gas) were 0. The calcn. method is further discussed. The results agreed with the equation given. For gasoline $q_1 = +0.0306$ C amps. was found.

B. J. C. VAN DER HOEVEN

The electrical moment of *p*-azoxyanisole. J. ERRERA. *Physik. Z.* 29, 426-9

(1928).—The dielec. const. of *p*-azoxyanisole was measured between 116° and 120° while the frequency was varied from one million to 400. At const. temp. the dielec. const. was independent of frequency, which indicates the presence of no rod-like aggregates of *p*-azoxyanisole mols and no dipole moment of the aggregate. The mols., however, have a permanent elec. moment, $\mu = 2.3 \times 10^{-18}$. MALCOLM DOLE

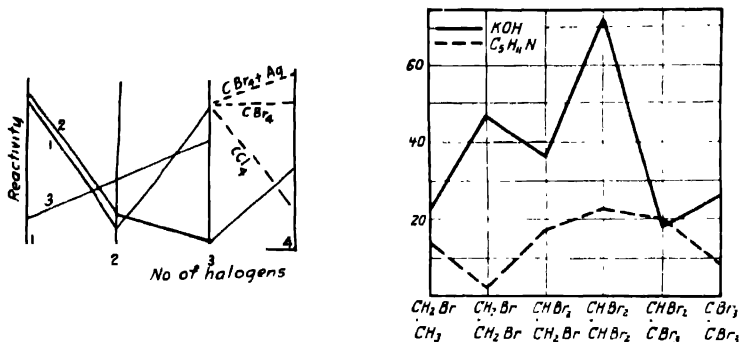

The magnetic moments of the cupric ion. FRANCIS BIRCH. *J. phys. radium* **9**, 137-41 (1928).—This is a somewhat more detailed account of the investigation previously reported by Collet and B. (*C. A.* **22**, 1528). The chief conclusion is that Cu^{++} regularly has a moment of 10 Weiss magnetons. A possible state having a moment of 9 magnetons is suggested by some of the results with CuCl_2 . Fractional moments in the neighborhood of 9.6 magnetons reported by earlier observers are ascribed to mixts. in varying proportions of the integral states. W. W. STIFLER

Magnetic transformations of the sesquioxide of iron, of its solid solutions and of its ferromagnetic combinations. H. FORESTIER. *Ann. chim.* **9**, 316-401 (1928).—Full exptl. details of app. and method, and complete results are given for work on which preliminary reports have already appeared (*C. A.* **20**, 698, 1939; **21**, 696). The technic is described for the prepn. from powd. substances, such as MgO , Al_2O_3 , Cr_2O_3 , Fe_2O_3 , FeO and various ferrites, without the use of any binder, of the small test rods for use in Chevenard's differential dilatometer (cf. *Rev. Met.* **14**, 610 (1917); cf. *C. A.* **11**, 2743). A comparative study of the dilatometric curves obtained with rods of the same oxide annealed from widely differing temps. indicates the absence of any allotropic transformations. The stable Fe_2O_3 is ferromagnetic (although its coeff. of magnetization is small) with 675° as the Curie point. Its temp. of magnetic transformation is lowered in solid solns. with Al_2O_3 or Cr_2O_3 . The prepn. of a no. of ferromagnetic ferrites is described. These include $\text{Fe}_2\text{O}_3\text{ZnO}$, stable, feebly magnetic; $\text{Fe}_2\text{O}_3\text{CaO}$ and $\text{Fe}_2\text{O}_3\text{CdO}$, unstable strongly magnetic, $\text{Fe}_2\text{O}_3\text{CuO}$, $\text{Fe}_2\text{O}_3\text{NiO}$, $\text{Fe}_2\text{O}_3\text{MgO}$, $\text{Fe}_2\text{O}_3\text{SrO}$, $\text{Fe}_2\text{O}_3\text{BaO}$ and $\text{Fe}_2\text{O}_3\text{PbO}$ stable, strongly magnetic. $\text{Fe}_2\text{O}_3\text{CaO}$ and $\text{Fe}_2\text{O}_3\text{CdO}$ lose their ferromagnetism irreversibly on heating, and are characterized by absence of residual magnetism and rapid attainment of satn. Both thermomagnetic and dilatometric study indicate the existence of the compd., $\text{Fe}_2\text{O}_3\text{MgO}$. All these ferromagnetic substances when heated and cooled in a const. magnetic field undergo an increase in residual magnetism. It is suggested that this property should be considered quite as characteristic of ferromagnetic substances as hysteresis. A recording app. for thermomagnetic analysis is described in detail. W. W. STIFLER

Theory of birefringence induced by flow in liquids. C. V. RAMAN AND K. S. KRISHNAN. *Phil. Mag.* [7], **5**, 769-83 (1928); cf. *C. A.* **20**, 539, **22**, 722.—In this paper a theory is developed for the effect discovered by Maxwell, viz., that a liquid in a state of viscous flow exhibits birefringence. The state of stress in the fluid consists of tensions and pressures in directions perpendicular to each other and inclined at 45° to the plane of sliding. When the mols. have an elongated form, these stresses tend to orient them so that their direction of greatest length lies along the axis of tension, and that of shortest length along the axis of pressure. The tendency to orientation is, however, resisted by their thermal agitation and the resulting state of statistical equil. may be found by application of Boltzmann's principle. The optical anisotropy of the mol. together with the orientations referred to, causes the medium to become birefringent. The magnitude of the effect is proportional to the product of the viscosity and the velocity gradient. The const. of proportionality, which is referred to as the Maxwell const. for the liquid, is evaluated in terms of the optical and geometrical anisotropies of the mol., the refractive index, density, and mol. wt. of the liquid, and Boltzmann's const. The data for 172 liquids recently obtained by Vorländer and Walter are critically discussed, and it is shown that the theory succeeds not only in giving an explanation of the general features of the phenomena, but also in giving quant. the observed values of the Maxwell const. GEORGE GLOCKLER

The law of periodicity. III. P. PETRENKO-KRITCHENKO, A. RAVIKOVICH, V. OPOTSKII, E. PUTYATUI AND M. DIAKOVA. *J. Russ. Phys.-Chem. Soc.* **60**, 149-52 (1928); *Ber.* **61B**, 845-54 (1928); cf. *C. A.* **21**, 3014.—Using compds. in which one function is repeated several times, the authors study their reactivity with the following reagents: KOH , NMe_3OH , $\text{Ba}(\text{OH})_2$, TlOH , H_2O , AgNO_3 , piperidine, MeONa and colloidal Ag. If halogen derivs. of methane, toluene, AcOH are considered, which contain an increasing no. of halogens in their mols., and the reactivity of their halogens is plotted, one of the curves given in Fig. 1 is obtained as follows: Iodo derivs. of methane curve 1 with AgNO_3 , NH_4OH piperidine; curve 2 with H_2O or alc. Chloro derivs. of toluene: curve 1 with piperidine and NH_4OH , curve 3 with Ag, H_2O , AgNO_3 . Chloro derivs. of AcOH is curve 1 with H_2O , 2 piperidine, 3 with Ag or AgNO_3 . Bromo derivs.

of AcOH. curve 1 with H_2O or $AgNO_3$, 2 with piperidine, 3 with Ag. Bromo derivs. of methane: curve 2 with piperidine

$CH_3(OEt)_2$, $CH(OEt)_3$, $C(OEt)_4$ and $(EtO)_2CHCH(OEt)_2$ have been saponified under the same circumstances; the percentages saponified were, resp., 13.6, 18, 9.7 and 3%. $CH_3(SH)CO_2H$ is more reactive than $CH_2(OH)CO_2H$; $O(CH_2CO_2H)_2$ is more reactive than $S(CH_2CO_2H)_2$. The repetition of a function in the same mol. lowers its reactivity, as shown by a comparison between $MeOH$ and $HOCH_2CH_2OH$, Ph_3COH and $Ph_2C(OH)C(OH)Ph_2$, $MeC(OH)CO_2Et$ and $EtO_2CCH(OH)CH(OH)CO_2Et$, NH_3 and H_2N-NH_2 , PH_3 and P_2H_4 , $CH_3(OEt)_2$ and $(EtO)_2CHCH(OEt)_2$. The reverse is true for a monoketone < α -diketone or HCO_2H < $(CO_2H)_2$. Fig. 2 shows the reactivity of the bromoethanes

An improved method of ultra-violet polarimetry. Anomalous rotary dispersion of sodium tartrate. THOMAS M. LOWRY AND MAURICE A. VERNON. *Proc. Roy. Soc. (London)* 119A, 706-9(1928).—An earlier method (cf. *C. A.* 3, 1117) is applied to solns. of Na tartrate which is shown to have anomalous rotary dispersion with max. α at $\lambda = 3586$ A. U.

A. P. S.

Dispersion and absorption of high-frequency sound waves. K. F. HERZFELD AND F. O. RICE. *Phys. Rev.* 31, 691-5(1928).—The absorption of sound waves in gases had been explained heretofore by friction and heat conduction. A third factor is here introduced, namely: The slow rate of exchange of energy between the translational movement and the internal degrees of freedom of the mols. The formulas detg. the absorption and dispersion of sound waves, due to these three effects, are developed. Comparison with the exptl. data available show that the new effect is either of considerable influence or even predominant. The rate of exchange can be calcd. B. L.

Rotatory dispersion of solutions. RENÉ LUCAS. *Ann. phys.* 9, 381-459(1928).—L. subjects mathematical relationships for additive properties of substances to analysis and arrives at conclusions enabling him to generalize the rule and diagram of Darmonis (cf. *C. A.* 6, 2888) hitherto applicable only to binary mixts. Assuming that optical rotatory power is additive for the mols. in equil. in tartrates, L. shows that the data are consistent within exptl. error for the criteria his analysis developed and consequently a study of rotatory dispersion fixes the number of constituents of a mixt. Rotatory dispersions of tartaric acid in various solvents (H_2O , solns. of $CaCl_2$, $CO(NH_2)_2$, H_3BO_3 , H_2SO_4 , Na tungstate and molybdate) and for 7 monochromatic radiations (from $\lambda = 6708$ to $\lambda = 4358$ A. U.) show that tartaric acid behaves in all cases as a mixt. of 3 active substances the proportions of which vary with the solvent. Similar results appear for pure Et tartrate and for solns. of Et and Me tartrates in various solvents and at

various temps. The origin of the 3 active forms is sought in the possibility that the mols. exist in 3 mol. configurations in equil. with discontinuous passage from 1 form into another. Stereochemical models are proposed based on assumption that a single $\equiv C - C \equiv$ linkage is rigid and not mobile as commonly assumed. The stereochemical models are

and correspond to the existence of 3 forms of ethylene chloride (instead of the 1 known). L. adduces support for his configurations from the structures of various derivs. of tartaric acid and from x-ray diagrams. The 3 forms of ordinary active *d*-tartaric acid have the following consts: (1) α -form (of Longchambon) *l*-rotatory, of same structure as mol. in crystal, $[\alpha]_D \leq -88^\circ$, and $[\alpha]_D/[\alpha]_D$ between 2.15 and 2.14. (2) β -form, *d*-rotatory, $[\alpha]_D \geq +27^\circ$ and $1.51 < [\alpha]_D/[\alpha]_D < 2$. (3) γ -form, strongly *d*-rotatory, $[\alpha]_D \geq +544^\circ$ and $[\alpha]_D/[\alpha]_D \geq 2.3$. A. P. SACHS

Experimental investigations on the origin of the moon craters: a new contribution to the explosion hypothesis. STJEPAN MOHOROVIĆIĆ. *Arch. hem. farm.* 2, 66-76 (1928).—F. E. Wright's observations (*Proc. Nat. Acad. Sci.* 13, 535-40 (1927)) help to throw light on the formation of the moon craters. The photographs made by M. showing the effects of explosions with $Mg + KClO_3$ in dry and wet cement powder display great similarities to moon craters. On this basis a new hypothesis of the formation of moon craters is suggested. JAR. KUČERA

Matter, energy, action. MAURICE SAUGER. *Rev. gén. sci.* 39, 234-9 (1928).—A concise discussion is given of the exact meaning and relation of the concepts of matter, energy and motion. L. D. ROBERTS

The question of the origin of the penetrating radiation. V. PERSHKE. *Z. Physik* 49, 740-1 (1928).—Substitution of selected data in the Balmer formula shows that the production of He atoms from H atoms is accompanied by radiation of wave length 10^{-13} cm. which is exactly the lower limit for the penetrating radiation. W. F. M.

Pressure of calcium in the sun's atmosphere. E. A. MILNE. Univ. Manchester. *Nature* 121, 1017-8 (1928).—From calcs. of Unsöld (cf. *C. A.* 22, 1277) the no. of Ca atoms per sq. cm. column of the sun's atm. is 2.3×10^{19} . According to M., these should be mostly confined to a relatively thin layer (100 km.) directly above the layer where complete opacity sets in. The pressure for complete opacity is calcd. as 4.1×10^{-6} atm., neglecting radiation pressure. M. had previously obtained 5.5×10^{-5} atm., using Kramer's theory for the absorption coeff. in the continuous spectrum due to the ejection of photoelectrons. The agreement points to this effect as the chief source of the sun's continuous spectrum. It is convenient to regard the chromospheric layer as sep'd. sharply from the reversing and photospheric layers. In the former there are few collisions, permitting monochromatic radiative equil., with a strong selective radiation pressure. In the latter, there is local thermodynamic equil., and the dissocn. of different kinds of ions is det'd. by Saha's theory. A table is given of the pressures of Ca, Ca^+ and Ca^{++} at the various levels of the solar atm. F. A. JENKINS

The energy distribution of complex molecules. OSCAR K. RICE. Cal. Inst. Tech. *Phys. Rev.* 32, 142-9 (1928).—It is shown that for any distribution law in which Boltzmann's law holds for the various quantum states, $d \log W/dT = (\bar{\epsilon}_w - \bar{\epsilon})/kT^2$, where W is the fraction of the mols. in certain specified quantum states, $\bar{\epsilon}_w$ the av. energy of the mols in these states, $\bar{\epsilon}$ the av. energy of all the mols., T the abs. temp. and k the gas const. The distribution law will appear to be continuous if not viewed too closely, even though motions of the mols are quantized. In this treatment the continuous outline is considered and the fine structure neglected. If $W_e d\epsilon$ is the fraction of mols. whose energy lies between ϵ and $\epsilon + d\epsilon$, the general rule is derived $\partial^2 \log W_e / \partial T \partial \epsilon = 1/kT^2$. Proceeding along these lines the distribution law over a range of energies is found in a new and simple way, if the av. energy of the mols. (or the energy at which W_e is a max.) is given over a range of temps. At a given temp. the actual distribution law is compared with a classical one which makes W_e have a max. at the same energy. A limit is found beyond which the actual distribution law cannot depart from this particular classical law, provided the mol. is made up of a group of rotators and harmonic oscillators, and is sufficiently complex. An example is considered which concerns the theory of the decompn. of azomethane. BERNARD LEWIS

Ionization of mercury atoms by their reaction with helium ions. J. STARK. *Ann. Physik* 86, 541-6 (1928).—Hg vapor pressure not more than 0.001 mm. was added to He or Ne varying from 0.5 to 150 mm. pressure and excited by a 3500 v. discharge, and current from 5 to 60 m.-amp. At large c. d. the emission of lines by Hg^+ ions (spark lines) in comparison with the emission of neutral Hg atoms (arc lines) is much stronger in a Hg-He than in a Hg-Ne mixt. W. F. MEGGERS

Diffraction of cathode rays by mica. S. NISHIKAWA AND S. KIKUCHI. Institute Phys. and Chem. Research, Tokyo. *Nature* 121, 1019-20 (1928).—A diffraction pattern obtained by passing a cathode ray beam through a thin sheet of mica is reproduced. The distance from the crystal to the plate was 12 cm., and the voltage about 50 kv. The pattern consists of 3 sets of parallel bands intersecting each other at 60° , giving a net of triangular mesh. The intersections form an array of spots, some of which are intensified and somewhat elongated. The distance between the parallel bands decreases with increasing voltage, and the distribution of the intensified spots is changed. A magnetic field shifts the pattern and the central spot by the same amt. The diffracted rays are more homogeneous as regards velocity than the primary ones. The net-like pattern may be interpreted as due to the diffraction of the de Broglie waves by a 2-dimensional triangular lattice. The distance between the parallel bands gives the right order of magnitude for the at. distance. The intensified spots may result from the fact that the diffracting lattice is appreciably 3-dimensional, and may correspond to the Lau spots. Their elongation may be due to distortion of the specimen. F. A. JENKINS

Studies on the detection of elementary transformation caused by cathode rays. A. KOENIG AND F. V. KÖRÖSY. *Z. Electrochem.* 34, 305-11 (1928); cf. *C. A.* 22, 1271.—The app. is described at length. No artificial radioactivity was detected since the normal curves of the electrometer vs. time fall exactly on the curves obtained after exposure to radiation. M. FENSKÉ

The index of refraction of the electron waves. L. ROSENFELD AND E. E. WITMER. *Z. Physik* 49, 534-40 (1928).—A theoretical, mathematical discussion of recent work

such as that of Davisson and Germer (C. A. 22, 350). A bibliography of 13 references is included.

Thermal agitation of electric charge in conductors. H. NYQUIST. Am. Telegraph and Telephone Co. *Phys. Rev.* 32, 110-3(1928).—*The e. m. f. due to thermal agitation in conductors is calcd. by means of thermodynamic and statistical mech. principles. The results obtained agree with exptl. results.*

BERNARD LEWIS

Thermal agitation of electricity in conductors. J. B. JOHNSON. Am. Telegraph and Telephone Co. *Phys. Rev.* 32, 97-110(1928).—Statistical fluctuations of elec. charge exist in small conductors, producing random variation of potential between the ends of the conductor. The effect of these fluctuations has been measured by a vacuum tube amplifier and thermocouple and can be expressed by the formula $\bar{I}^2 = (2kT/\pi) \int_0^\infty R(\omega) |Y(\omega)|^2 d\omega$. I is the observed current in the thermocouple, k is Boltzmann's gas const., T the abs. temp. of the conductor, $R(\omega)$ is the real component of impedance of the conductor, $Y(\omega)$ is the transfer impedance of the amplifier, and $\omega/2\pi = f$ represents frequency. The value of Boltzmann's const. obtained from the measurements lies near the accepted value. The technical aspects of the disturbance are discussed. In an amplifier having a range of 5000 cycles and the input resistance R the power equiv. of the effect is $\bar{I}^2/R = 0.8 \times 10^{-16}$ watt, with corresponding power for other ranges of frequency. The least contribution of tube noise is equiv. to that of a resistance $R_c = 1.5 \times 10^6 i_p/\mu$, where i_p is the space current in milliamp. and μ is the effective amplification of the tube.

BERNARD LEWIS

Recent light on the nature of gaseous ions. LEONARD B. LOBB. Univ. of Cal. *Phys. Rev.* 32, 81-96(1928).—*The nature of gaseous ions from a study of mobilities in mixts. After a general survey of the previous status of the question of the nature of the gaseous ion, it is concluded that for pure gases the dielectric attraction of the mols. by the charged ion can account for the order of magnitude of the mobility nearly equally well on either the cluster or small ion theory. Such calcns. are therefore indecisive. The measurements of mobilities in mixts. use Blanc's law as a criterion for the absence of the change of the cluster ion. The results show that the law held in some cases but not in others. The observed nature of the mobility curves in mixts. shows 3 types of effects. These may be interpreted as indicating absence of clustering, labile clustering, stable clustering. The nature of the deviations in different gases indicates that where marked clustering occurs it is a sp. effect depending on the chem. nature of the gas and sign of charge on the ion. Such effects are superimposed on the dielectric attractions mentioned above. Erikson's results on aging are discussed.*

BERNARD LEWIS

The voltage-current relation in central cathode photoelectric cells. THORNTON C. FRY AND HERBERT E. IVES. Bell Telephone Lab. *Phys. Rev.* 32, 44-56(1928).—This paper presents a theoretical basis for the interpretation of the exptl. results described in the following abstract. It considers a source of photoelectrons located on the inner of 2 concentric spheres; derives the trajectory of an electron shot off at any angle at any speed; and then makes use of this information to compute the current which would be received by a small collector located anywhere on the outer sphere upon very general assumptions as to the directional distribution and velocity distribution of the photoelectrons. This theoretical study is followed by graphical presentation of results computed for several typical cases of special interest in connection with the exptl. study.

BERNARD LEWIS

The distribution and direction of photoelectrons from alkali metal surfaces. HERBERT E. IVES, A. R. OLPIN AND A. L. JOHNSRUD. Bell Telephone Lab. *Phys. Rev.* 32, 57-80(1928).—An exptl. study was made of the distribution in direction of photoelectrons emitted from alk. metal surfaces irradiated by light incident at various angles and polarized in different planes. The alk. metal surfaces used were of 2 sorts: (1) liquid alloys of Na and K, (2) thin films of K or Rb on polished Pt. In all cases the surface was at the center of a large spherical enclosing anode, provided either with collecting tabs at various angular positions or with an exploring finger. Emission closely obeyed Lambert's law, but the ellipse by which the emission was represented, in polar coordinates, was more elongated normally to the surface for perpendicularly incident light than for obliquely, when the direction of the elec. vector was in both cases parallel to the surface, and still more elongated for obliquely incident light with the elec. vector in the plane of incidence. The distribution curves are all perfectly sym. about the normal to the surface, showing no tendency to follow the direction of the elec. vector.

BERNARD LEWIS

Decomposition of the Faraday effect into two phenomena of different origins. Rotary diamagnetic polarization and rotary paramagnetic polarization. JUAN BAC-

QUERREL AND W.-J. DE HAAS. *Compt. rend.* 186, 1720-2(1928).—In 1908 B. showed that the magnetic rotary power (in the neg. sense) of certain rare earth minerals varies very nearly inversely as the abs. temp. (*Le Radium* 5, 16-7(1908).) The resemblance to Curie's law led him to affirm the existence of a paramagnetic rotation essentially distinct from the diamagnetic rotation. This has now been confirmed by expts. made at Leyden at temps. of 4.21° abs., 1.71°, 1.41° and 1.39° on 2 specimens of tysonite. The rotation, ρ , produced by a magnetic field, H , is given very exactly by the relation $\rho = \rho_{\infty} \tan h(AH)$, where ρ_{∞} , the rotation at satn., is a function both of the wave length of the light used and of the temp., and A is a function of the temp. only. The theory of magnetization in the principal direction of a crystal leads to the relation $A = \Sigma_{\infty}/RT$, where Σ_{∞} is the product of the moment of the elementary magnet by Avogadro's no., and R is the gas const. The values obtained for Σ_{∞} are very close to the Bohr magneton. W. W. STIFLER

Investigations on bismuth by the magnetic-molecular-ray method. ALFRED LEU. *Z. Physik* 49, 498-506(1928); cf. *C. A.* 21, 1754.—Mol. rays from Bi were studied by the Gerlach-Stern method. Details are given for a new steel vaporizing chamber arranged for heating by electron bombardment. Temps. from 800° to 1150° approx. were used. Two symmetrical deflected rays were obtained, as well as an undeflected ray. The intensity of the latter diminishes with increase of temp. and it is therefore attributed to the Bi₂ mol. The deflected rays are ascribed to Bi atoms. The observed deflections agree well with theory and indicate a magnetic moment of 0.85 Bohr units. A rough calcn. of the heat of dissocn., based on the change of intensity with temp. of the undeflected ray, gave 60,000 ($\approx 15,000$) cal, which agrees well with the value 56,000 cal. computed by the Nernst theory. W. W. STIFLER

Elementary theory of the magnetic and electrical properties of the metals at zero absolute. I. FRENKEL. *Z. Physik* 49, 31-45(1928).—The application of the Pauli-Fermi theory to the electrons in a metal rests on the assumption that in every phase cell of vol. h^3 there can be at most only 2 electrons, and this is possible only when their magnetic axes are oppositely directed. At zero abs. the distribution of electrons is detd. by the condition that the total energy shall have the least possible value. From this it follows that all the electrons will be combined in magnetic "married couples" ("magnetischen Ehepaare"). On this basis equations are derived for the paramagnetic state, and a more qual. discussion of ferromagnetism is given. The work necessary to liberate the free electrons is computed according to the virial law, and equations are developed for contact difference of potential, pressure and compressibility. W. W. S.

The diamagnetic layer of the earth's atmosphere and its relation to the diurnal variation of terrestrial magnetism. ROSS GUNN. Naval Research Lab. *Phys. Rev.* 32, 133-41(1928).—An investigation of the motion of ions and electrons in the region of long free paths shows that the elec. cond. in the direction of the earth's magnetic field is that predicted by simple theory. It appears that large circulating currents in the upper atm. of the type assumed in present theories of the diurnal terrestrial magnetic variations are hardly possible. A theory of the diurnal magnetic variation is worked out which explains quantitatively the major phenomena in terms of the diamagnetic effect produced by ions spiralling about the earth's magnetic field. The diamagnetic intensity of magnetization of the upper atm. in the region of long free paths depends upon the total no. of ions of all kinds per cc., their mean kinetic energy and the impressed magnetic field. The max. calcd. diurnal magnetic variation as a function of latitude agrees in form with observation. The av. max. no. of ions of all kinds per cc. in the upper atm. was then computed from observed magnetic data and found to be approx. 5×10^{10} , a no. not inconsistent with the ionic d inferred from data derived from radio phenomena. BERNARD LEWIS

The x-ray diagnosis of chemical and industrial materials, and a new type of biological diagnosis. GEORGE L. CLARK. Univ. of Ill. *Radiology* 10, 185-98(1928); cf. *C. A.* 21, 2427.—The chem. and industrial science of x-rays has 4 phases: (1) Spectroscopy. This is applied to the discovery of new elements and to the quant. and qual. analysis of mixts. (2) Direct chem. and elec. effects. A large number of these are known, and work along these lines is being done in the attempt to explain various biol. phenomena. (3) Radiography. Aside from its application in medical fields, this branch has many useful industrial applications. All sorts of opaque objects can be investigated during or after their manuf. (4) Fine structure of materials. The x-ray diffraction method can be applied to crystals, colloids or amorphous substances, and yields much information as to phys. and chem. properties. A very large number of actual applications of this method are given. E. H. QUIMBY

X-rays in science and industry. WHEELER P. DAVEY. Penn. State College.

Radiology 11, 101-14(1928).—X-rays are useful to industry in 2 ways—in getting the factory out of manufacturing difficulties, and in the search for new scientific principles which may serve to correlate and explain known facts or be applied to the development of new structural products. The solution of factory difficulties consists mainly in finding flaws in castings. The analysis of crystal structure makes possible the prediction of some mech. properties of metals and their behavior in alloys. Plasticity or ductility depends on the slipping of planes of atoms upon adjacent planes. Slipping takes place along the planes having the greatest atomic population, and these can be found for each type of structure. Hardness involves resistance to interplanar slip. Most alloys are ionic in nature, the electropositive metal giving over some or all of its valence electrons to the electronegative, producing a crystal structure of non-ductile type, harder than either constituent. The changes of behavior of Fe with heating can be explained by changes in structure of the Fe and in the positions of the atoms of alloy materials, particularly C, with reference to the Fe. The C atom acts like a tetrahedron. The shapes of the mols. in the paraffin and benzene series are being investigated. Studies on stretched rubber, gelatin, shellac, etc., are proving of practical importance. A good bibliography is appended. E. H. QUILMBY

Is the crystal reflection of x-rays entirely a classical phenomenon? G. E. M. JAUNCEY AND W. P. CLAUS. *Nature* 121, 983 (1928).—Recent papers by Woller and by Wentzel state that the regular reflection of x-rays can be treated as a purely classical phenomenon and that the modified scattering of the Compton effect can be disregarded. A mathematical treatment of the subject shows that the requirements of the classical theory are not satisfied by the assumptions accompanying this theory. G. L. C.

An experimental study of the relative intensities of x-ray lines in the L-spectrum of uranium. SAMUEL K. ALLISON. *Univ. of Cal. Phys. Rev.* 32, 1-11(1928).—The relative intensities of 17 lines in the L-spectrum of U have been measured as a continuation of previous work (*C. A.* 21, 3549). Changes in the app. are described which reduce the magnitude of the corrections to be applied. The variation of the intensity of $U L\alpha$ with voltage has been studied and may be closely represented by $I = C(V - V_0)^{1.8}$, and with less accuracy by a function $I = C[(V - V_0)/V_0 - \log(V/V_0)]$. The observed results at 52.8 kv. have been extrapolated to the relative intensities at voltages very much greater than the crit. voltages. Important results are: (1) The lines $\gamma_4\gamma_1$ and $\beta_3\beta_4$, known in other elements to deviate from the sum rule predictions, have equal intensities in U although a ratio 2:1 is predicted. (2) The lines $\gamma_4\beta_3$ are 17 times more intense in U than in W presumably because of the filling of the γ_4 orbits in the intervening elements. (3) The lines $\gamma_4\gamma_6$ which are present in the W spectrum are absent in the U and Th spectra. It is shown that if the second function above holds for electron collisions in which the velocity of the impinging electron is great compared to the velocities of the electrons in the atom, the relative intensities of lines of a multiplet under these conditions are equal to the product of the transition probability by the statistical wt. of the initial state with only a slight correction. The results are:

	I	α_2	α_1	η	β_4	β_3	β_4	β_1	β_4	β_1	β_3	γ_4	γ_1	γ_2	γ_3	γ_4	γ_5
Relative intensities at 52.8 kv.	2.4	11	100	0	83	1.6	28	3	2	0.4	6.4	40.5	3.3	0	9.7	1.1	1.1
Relative intensities at high voltage	2.4	11	100	1.0	1	6	28	4	1	0.4	6.4	49.4	4.2	0	12	1.5	1.4

BERNARD LEWIS

Evidence obtained by x-ray analysis of films of iron in magnetic fields as to the ultimate nature of magnetism. T. D. YENSEN. Westinghouse Lab., East Pittsburgh. *Phys. Rev.* 32, 114-23(1928).—The results of other workers showed that there is no change in crystal structure of single crystals of magnetite and hematite when placed in strong magnetic fields. In the present investigation films of electrolytic Fe were analyzed by x-rays to det. whether there is any change in the random orientation of the minute crystals (of the order of 150 A. U.) found in these films when placed in strong magnetic fields (up to 2600 gauss). If so, the uniform circular diffraction patterns resulting from the randomly oriented crystals should, because of the preferred orientation, be changed to show greater or less d. along a diam. parallel to the applied magnetic force than along the other, perpendicular to it. The circles were analyzed micro-photometrically and the results indicate no change in the orientation. The av. of all the measurements is a ratio of the intensities along the 2 diams. of 1.00 ± 0.08 , the variation being attributed to incidental sources arising from the developing and

handling of the film. Conclusion: The most minute crystal aggregates in Fe are not oriented in a magnetic field. This lends strength to the previous conclusion in regard to the ultimate nature of magnetism, namely, that the magneton is an at. property.

BERNARD LEWIS

The scattering of x-rays from gases. CHARLES S. BARRETT. Univ. of Chicago. *Phys. Rev.* 32, 22-9(1928); cf. *C. A.* 22, 1275.—Intensity of the scattering of Mo x-rays from CO_2 , A, O_2 , N_2 , He and H_2 at scattering angles from 20° to 155° . All except H_2 show excess scattering (with He it may be due to N_2 impurity): the excess scattering extends to larger angles from the primary beam as the at. no. of the gas increases and as the wave length increases. This excess scattering appears to be mostly, if not wholly, due to interference arising within the atom. Destructive interference is prominent with A, and seems probable (though it is very weak) with O_2 , CO_2 and N_2 . Mark and Schocken's (*C. A.* 21, 1730) results, which indicated scattering by gases follows the $(1-\cos^2\theta)$ law, are not confirmed. H_2 follows within exptl. error the quantum theory prediction of Breit, Dirac, Gordon and Waller. Even when the K-rays of Mo are used the scattering from H_2 does not show the irregularities by Debye's interference theory.

BERNARD LEWIS

Interpretation of atomic structure factor curves in crystal reflection of x-rays. G. F. M. JAUNCEY AND W. D. CLAUS. Wash. Univ., St. Louis. *Phys. Rev.* 32, 12-21 (1928).—The authors showed previously (*C. A.* 22, 2712) that for certain values of D the grating space of a crystal of rock salt the area under a radial electron distribution (or U) curve for Cl rose above 19 electrons. This result seemed perplexing, inasmuch as both the real ion and the model ion have but 18 electrons. The present paper is a further discussion of this point. It is proved that for any sym. atom F values, calcd. according to the classical theory and unmodified for the Compton effect, but multiplied by the Debye temp. factor, give U curves the areas under which never exceed the no. of electrons assumed in the model. It is also shown that an unsym. atom gives F values which behave in the same way. But since both exptl. and modified theoretical F values (that is, modified to take account of the Compton effect) give U curves the areas under which do exceed the true no. of electrons for certain values of D , there is an indication that the Compton effect is involved in the exptl. values. The truth of this indication would invalidate the use of the Fourier analysis method as now applied. The present paper also develops the Fourier integral as a quick method of calcg. a U curve from a model atom on the classical theory. It is shown that a U curve calcd.

from Compton's formula $U = (8\pi r/D) \sum_1^n (nF_n/D) \sin(2\pi rn/D)$ for a Fourier series is a very close approx. to the true U curve given by the Fourier integral $U(r) = 8\pi r \int_0^\infty x F(\lambda x/2) \sin 2\pi r x dx$, where F is the same function of $(\lambda x/2)$ as F in the series formula is a function of $\sin \theta$. An analysis by the Fourier integral of a model supposed to have all the electrons cond. at the center together with the Debye temp. factor shows $U(r)$ represents the distribution of electrons about a lattice point and not about the center of the atom.

BERNARD LEWIS

Test of the theory of R. W. Gurney with the helium lines of the chromosphere. WILHELM ANDERSON. *Z. Physik* 49, 479-52(1928).

W. F. MEGGERS

The elimination of Doppler effect in spectroscopic fine-structure and the exact determination of components. GUSTAV DOETSCH. *Z. Physik* 49, 705-30(1928).—Every spectral line is widened in consequence of the Doppler effect of the emitting atoms in thermal agitation; the intensity curve is a Gauss error function. Close lines such as fine-structures overlap on this account and the resulting displacement of the max. makes it impossible to obtain the exact wave-nos. of the components or even to establish the no. of components directly from the observed intensity curve. Two methods for the exact detn. of the components, i. e., for the resolution of a given function into Gauss error-curves, are presented, the first being a direct method and the second involving a reduction of the problem to one in heat cond. The methods are tested on intensity measurements of the H α line by Oldenberg and by Hansen. It is demonstrated that H α consists of at least 3 components.

W. F. MEGGERS

The $K\beta_1$ -line of the elements potassium to manganese. TORSTEN WETTERBLAD. *Z. Physik* 49, 670-3(1928).—New measurements of the wave-length differences $K(\beta_1 - \beta_2)$ of the elements 19 K to 25 Mn confirm earlier results by Bäcklin, Siegbahn and Thoriaeus showing an irregularity for K and Ca. Incidentally it is shown that the wave length of $K\beta_1$ depends in marked degree on the chem. binding. Thus as compared with anticathode of metallic Ca, one of CaO shifted the β_1 line 3.3 X. U.

W. F. M.

New regularities in the band spectrum of helium. I. G. H. DIBKE, T. TAKA-

MINE AND T. SUGA. *Z. Physik* 49, 637-69(1928).—A Pyrex glass tube about 1 m. long and 20 mm. in diam. contg. He gas at pressures varying from a few mm. to several cm. was excited by a condensed discharge from two 0.3 kw. transformers in parallel and the spectrum was photographed with a concave grating of 15 feet radius. Many new lines were recorded; the wave lengths and estd. intensities of lines belonging to the orthobands (λ 588, 589, 595, 445 m μ) and the para bands (λ 659, 624, 625, 631 m μ) are given in tables showing the P-, Q- and R-branches and quantum jumps. All of these new bands have properties which deviate considerably from the previously known terms. The present paper is restricted to a presentation of the empirical regularities, their interpretation is reserved for a later communication. Also in *Nature* 121, 793-4(1928). W. F. MEGGERS

The structure of the negative nitrogen bands. GERHARD HERZBERG. *Ann. Physik* 86, 189-213(1928).—An electrodeless ring-discharge in N₂ at very low pressures (0.05 to 0.01 mm.) produces the negative N₂ bands remarkably free from other bands and lines. These are photographed with prism-spectrographs and the wave lengths corresponding to the band heads are measured. The bands in the visible spectrum are thus traced for the first time to the point of inversion and even beyond. Nuclear vibration frequencies of the initial and final states are derived from these and a value of 3.5 v. is obtained for the dissoen. potential of the N₂⁻ mol. in the excited state. W. F. MEGGERS

A new regularity in the intensity ratio of the principal series doublets of the alkalis. S. SAMBORSKY. *Z. Physik* 49, 731-9(1928).—Although the intensity ratio of the resonance pair of lines of the alkalis (first member of the principal series) is usually observed as 2:1 in agreement with theory, various observers have found that the higher doublets deviate from this rule. Previous measurements, however, did not extend beyond 2 or 3 members of a series. Chlorides of the alkalis were vaporized in C arcs operated with 0.2 to 3.5 amp., 440 v., and the relative intensities of the successive members of series and intensity ratios of the doublets were detd. by photographic photometry. For Cs, the value 2 is adopted for the first doublet and the following values are measured for the succeeding 7 doublets: 5, 10, 15.5, 25, 15.8, 5.7, 4.5. The striking and entirely new phenomenon here shown is the rapid decline of the intensity ratios for doublets beyond the 5th, after a systematic increase had raised the value from 2 to 25. A similar trend is observed for Rb in which the intensity ratios for doublets 3 to 5 are detd. to be 3.5, 4.3, 5, 3. An empirical relation, $J_1/J_2 = cn^{0.66}$, represents the intensity ratios as a function of the effective quantum nos. of the p -terms up to the 5th but it is not valid beyond the inversion point. W. F. MEGGERS

Intensity ratio of the o - and p -series in relation to the atomic structure of helium. J. STARK. *Ann. Physik* 86, 530-40(1928).—The He spectrum consists of a group of series of singlets (p -series 2S — mP, etc.) and a group of series of triplets (o -series, 2s — mp, etc.). A p -series of the type 1S — mP is also known but an attempt to find a corresponding 1s — mp series failed. The ratio of intensity of the p -series to that of the corresponding o -series when excited by cathode rays decreases with increasing gas pressure; at the same pressure it is greater for high-speed cathode rays than for slow cathode rays and for canal rays. These facts may be simply explained on the basis that a p - or singlet-state is less stable and therefore does not occur as frequently as the o - or triplet-state. W. F. MEGGERS

The intensity ratio of the principal series doublets of the alkali metals. HANS JAKOB. *Ann. Physik* 86, 449-93(1928).—Using the method of photographic photometry suggested by Merton the intensity ratio of the components of the second doublet in the principal series of K, Rb and Cs is measured and its dependence on vapor density is detd. Solns. of various concns. were introduced in an oxy-hydrogen flame of least possible thickness to avoid reversal. The ratio of line intensities for K (4044 A. U./4047 A. U.) is about 2.00 for concns. under 4% but falls to 1.80 for concns. of 10%. The ratio for Rb (4202 A. U./4216 A. U.) is 2.06 for concns. of 1/4% but decreases to about 1.78 for 20%. Similarly the ratio for Cs (4555 A. U./4593 A. U.) decreases from 4.16 to 3.12 as the concn. is increased from 1 to 20%. The results for Rb and Cs are checked by measurements of the line absorption according to the method first described by Gouy. The true intensity ratio of the lines in the second member of the principal series is 4.0 for Cs and certainly greater than 2.3 for Rb. These results are evidently in conflict with the quantum intensity rule according to which the intensity ratio of the lines in question should be 2.0. W. F. MEGGERS

The question of spectral-line intensity. A. KUPFER. *Ann. Physik* 86, 511-20(1928).—The new mechanics of Heisenberg and Schrödinger is employed to calc. the intensities of "partial series" the algebraic sum of which represents the total intensities

of the Lyman-, Balmer-, Paschen- and Brackett-series of H. On account of the extraordinary sensitiveness of H-line intensities to small variations in observing conditions it is impossible to test these results with expts. but some further cases are computed and found to be in good agreement with measurements in Li and Na spectra.

W. F. MEGGERS

Regularities exhibited between certain multiplets for elements in the second long period. R. C. GIBBS AND H. E. WHITE. *Proc. Nat. Acad. Sci.* 14, 559-64(1928).—If, for a sequence of iso-electronic systems starting with any element in the periodic table, the energy levels representing any of the possible electron configurations be plotted on a Moseley type of diagram, the lines connecting points for corresponding terms of each successive element will be very nearly straight lines. Furthermore, it is found that the radiated frequencies resulting from those electron transitions involving no change in total quantum no. are displaced to higher and higher frequencies by very nearly a const. value. These general rules, the regular displacement of multiple levels and of multiplets, which were found to hold so well for sequences of iso-electronic systems in the first long period (*Phys. Rev.* 31, 309(1928)) have now been extended to the elements in the second long period, Rb to Ag.

W. F. MEGGERS

Absorption curves of the pulegonenols. JEAN SAVARD. *Compt. rend.* 186, 1738-41 (1928); cf. *C. A.* 22, 3157.—A study was made of the ultra-violet absorption spectra of pulegone, isopulegone and the corresponding enols. A comparison of the curves shows that the replacement of the CO group in the pulegones by the =C(OH) group causes (1) the disappearance of the first band (at about 3000-3200 A. U.) attributed to CO, (2) the appearance of part of a band, probably due to OH, in the extreme ultra-violet, and (3) no appreciable change in the position of the band due to C=C, but a decrease in the value of the intensity of max. absorption.

LOUISE KELLEY

The reaction between bromine and hydrogen in light of various wave lengths. W. JOST. Univ. Berlin. *Z. physik. Chem.* 134, 92-6(1928).—Borosilicate tubes contg. a mixt. of Br and H were illuminated by means of a Hg lamp, equipped with various filters. The HBr formed was measured, a check being obtained by the Br left intact. The precision of the measurements is not very high. From the exptl. results, the Bodenstein-Lütkenmeyer const. (cf. *C. A.* 19, 2453) has been calcd. in each case.

A. L. HENNE

Ultramicroscopic observations of silver bromide crystals. K. SCHAUM AND F. KOLB. *Z. wiss. Phot.* 25, 290-1(1928).—In light of long wave length (green to red) "optically empty" crystals did not show any change; in pre-exposed crystals, the no. of diffraction disks increased (photographic Becquerel effect). With very long exposure reversal of the color sequence could be observed; with red exposure a change in color from white to red was observed.

A. P. H. TRIVELLI

Influence of substitution of halogens, alkyls and amino groups on color and absorption spectra of indigo, thioindigo and indirubin. JAROSLAV FORMÁNEK. *Chem. obsor* 3, 133-41(1928).—Cl and Br atoms introduced into the benzene nucleus of indigo shift its absorption bands toward the red the more the larger the no. of halogen atoms, Br more than Cl atoms. Alkyl groups introduced into the benzene nucleus of indigo shift the absorption comparatively slightly; the shifting, however, is remarkable when introduced into the imino group of indigo. Two absorption bands are formed when halogens and alkyl groups are introduced into 6.6' position and both are shifted considerably toward the violet. Monothioindigo and thioindigo show 2 absorption bands shifted toward the violet. The changes in absorption caused by substitution are analogous to those of indigo derivatives. Indirubin gives non-fluorescing, red solns. and its derivs. show analogous changes in absorption spectrum to those of thioindigo derivatives.

JAROSLAV KUCERA

New type of discharge in neon tubes. F. A. LONG. Univ. Leeds. *Nature* 121, 1020(1928).—A com. Ne lamp is connected across the coils of an electromagnet excited by 110 v. On breaking the current, a new type of discharge is produced in the Ne tube. The relations between current, voltage and time are studied with a cathode ray oscillograph. Because of the self-induction, the voltage rises instantaneously to 300-400 v. and then drops to about 11 v. At this point the current attains a max. of over 6 amp. The voltage has a second small max. after about 1/2 second, at which time the current has fallen to zero. The extinction voltage is different from that with the ordinary discharge, and 3 or 4 successive flashes are sometimes seen.

F. A. J.

The arc spectrum of chlorine. OTTO LAPORTE. Imperial Univ., Kyoto. *Nature* 121, 1021(1928).—By the method used by Wood and Kimura to sep. the arc lines and spark lines of I, it has been possible to identify 23 arc lines of Cl in the region 4200-4700 A. U. They are due to transitions from the configuration $4p^4$ to $4s^4$. The analysis

leads to the identification of 3 pairs of ultra-violet lines $3p^4, 4s \rightarrow 3p^4$ found by Turner. The spacing of the terms in these states is normal, showing the usual vector coupling, but the higher states arising from $3p^4, 4p$ are of a different character, resulting in some ambiguity in the assignment of l values. F. A. JENKINS

The spectrum of the hydrogen molecules. O. W. RICHARDSON and P. M. DAVIDSON. King's College. *Nature* 121, 1018(1928).—Using the new wave-length measurements of Gale, Monk and Lee (*C. A.* 22, 1727), the combination relations in the bands of the H_α , H_β and H_γ systems are checked with considerable accuracy. The band systems in the violet are extended, and the numerical values for the vibrational term differences in the lower electronic state are given. The latter agree well with those of the B state of the far ultra-violet bands. The identity of these 2 states is further confirmed by calcs. of the moment of inertia. The bands now known account for about half the total intensity of the secondary H spectrum. The intensity ratio of 3 to 1 for successive lines in a band is found to hold in all cases. F. A. JENKINS

Light dispersion by two absorbing media. I. PLOTNIKOV and K. WEBER. *Z. Elektrochem.* 34, 316-20(1928).—See *C. A.* 21, 3314. M. FENSKKE

Relations between the absorption of light and chemical constitution. MARCEL BOUIS. *Rev. gén. sci.* 39, 240-5(1928).—The analysis of the spectra of absorption permits the detn: (1) of the different states of electronic activation of the mols.; (2) of the different frequencies of the atoms; and (3) the various values of the moments of inertia of the mols. L. D. ROBERTS

Explanation of some properties of spectra by the quantum mechanics of the spinning electron. II. J. V. NEUMANN and E. WIGNER. *Z. Physik* 49, 73-94(1928).—With the aid of the kinematical fundamentals presented in Part I (*C. A.* 22, 1729) the spectroscopic facts derivable from the Pauli model of the spinning electron are now investigated. The building-principle of series spectra, the selection rules for inner- and magnetic-quantum nos., and the quadratic Stark effect are treated. W. F. M.

The absorption of excited mercury vapor and the reversal of the green line and its satellites. M. PONTE. *Compt. rend* 187, 37-9(1928). W. F. MEGGERS

The spark spectra of chlorine and bromine. LEON BLOCH and EUGENE BLOCH. *Ann. Phys.* 9, 534-5(1928).—About 200 lines previously published (*C. A.* 21, 2845; 22, 914) as characteristic of the spark spectra of Cl and Br are withdrawn, they are explained as fourth order grating spectra overlapping the third order. W. F. M.

Spectra of krypton and xenon in the extreme ultra-violet. J. H. ARBINK and H. B. DORGELO. *Z. Physik* 47, 221-32(1928); cf. *C. A.* 22, 1540. B. C. A.

The relative intensities of the spectral lines H_α (H) and D_α (He) at different levels in protuberances. E. J. PEREPILKIN. *Z. Physik* 49, 295-305(1928). W. F. M.

The influence of a magnetic field on the band lines of the third positive nitrogen group. B. POGÁNY and R. SCHMID. *Z. Physik* 49, 162-6(1928).—A quartz tube contg. air at 5-mm. Hg pressure was operated with 5000 to 7300 v. d. c. and 0.1 to 0.2 amp. The tube was placed between the poles of an electromagnet, observations being made perpendicular to the lines of force and to the tube axis. At 26,000 gauss the most of the lines appear to be resolved into doublets with nearly the same sepn. as the normal Zeeman triplet. W. F. MEGGERS

The arc spectrum of uraninite from Kasolo. J. VERHAEGHE. *Bull. sci. acad. roy. Belg.* 14, Nos. 1-2, 18-30(1928).—Spectral analysis of uraninite from Kasolo was undertaken to det. if it differs in compn. from other samples of pitchblende analyzed chemically. The arc spectrum was photographed and several hundred strong lines between 3450 Å. U. and 4800 Å. U. were identified. On account of the greater sensitiveness of spectral methods, a no. of elements not chemically detected in U. minerals, were found; these included Ti, Ir, V, Th, W. W. F. MEGGERS

The spark spectrum of sodium. S. FRISCH. *Z. Physik* 49, 52-8(1928).—The spark spectrum of Na was produced by a d. c. discharge of 60 to 120 m. amp. (1500 to 2500 v.) in a tube with hollow cathode. The wave-lengths of 109 lines ranging from ultra-violet, 2493.19 Å. U., to violet, 4087.7 Å. U. are measured, and 40 of them are represented as combinations of 4 s -terms and 10 p -terms similar to those in the Ne spectrum. The differences between the s -terms of Na^+ are as follows: $s_1 - s_2 = 2481.3$, $s_4 - s_3 = 592.3$, $s_5 - s_4 = 765.6$. W. F. MEGGERS

Series in the spark spectra of germanium. K. R. RAO and A. L. NARAYAN. *Proc. Roy. Soc. (London)* A119, 607-27(1928).—The spark between Ge electrodes in an atm. of H_2 was photographed with a 5-foot concave grating and a large quartz spectrograph. Lines belonging to different stages of ionization were recognized by their behavior upon changing the self-induction or capacity in the circuit. 80 lines including doublets of Ge II, singlets and triplets of Ge III and doublets of Ge IV are classified.

The largest term of the Ge II spectrum is $^3P_1 = 128,635$, which corresponds to a second ionization potential of about 15.88 v. W. F. MEGGERS

Absorption investigations in excited hydrogen. NATHAN ROBINSON. *Z. Physik* 49, 137-45(1928).—The purpose of this investigation was to det. by means of absorption expts. the life of the at. state necessary for the absorption of the Balmer series. The method was similar to that devised by Meissner for observations on the rare gases (*Physik. Z.* 26, 766(1925) and *C. A.* 22, 1721) except that shorter-time intervals were obtained by employing oscillating condenser discharges and Holtz valve tubes as rectifier. The theory of the expt. is as follows: emission and absorption tubes are arranged end to end, and alternately excited. Absorption can occur only if the necessary excited at. states have not damped down in the absorption tube before the emission tube is again lighted. If one excites the tubes with a. c. of known period and employs suitable valves, one can det. from this the duration of the atom in the particular state required for the absorption. In the present case measurements were made with frequencies up to 5×10^6 per sec. but no absorption of $H\beta$ was detected. From this it follows that the life of the at. states capable of absorbing the Balmer series is less than 10^{-8} sec. at a pressure of about 0.5 mm. H. W. F. MEGGERS

Term representation of the band spectra of the neutral oxygen molecule. W. OSSENBRÜGGEN. *Z. Physik* 49, 167-216(1928).—A detailed analysis of the Schumann bands of O_2 in the ultra-violet, the Runge bands and the Fuchtbauer bands is presented; the oscillation and rotation terms are established and show that all these bands belong to one and the same system. Similar analysis of the atm.-O bands, A, B, α , α' and α'' confirms the suspicion that the Schumann bands and the atm. bands have a term in common. Another set of bands, called A', is assumed to belong to the same system as the atm. bands. The moment of inertia of O_2 in unexcited vibrationless condition is 19.20×10^{-40} g. sq. cm., and the at. sepn. is 1.201×10^{-8} cm. W. F. M.

Metallic reflection from rock-salt and sylvite in the far ultra-violet. A. H. PFUND. Johns Hopkins. *Phys. Rev.* 32, 39-43(1928).—From the rapid rise of the dispersion curve of rock-salt and sylvite in the ultra-violet the existence of regions of anomalous dispersion in the Schumann region have been long anticipated. By using a specially constructed vacuum tube in connection with a vacuum spectrograph the regions of metallic reflection for NaCl and KCl were found. From these results an est. was made of the wave lengths of the true resonance frequencies. The values 1547 Å. U. for NaCl and 1581 Å. U. for KCl are in agreement with those previously calcd. by Herzfeld and Wolf. BERNARD LEWIS

The first spark spectrum of palladium (Pd II). A. G. SHENSTONE. Princeton. *Phys. Rev.* 31, 30-8(1928).—The present analysis of Pd II differs completely from that given by McLennan and Smith. The terms found include $4d^3D(4d^3)$; $5s^4^2F$, $4s^3P$, 3D , $^3G(4d^35s)$; all the related triads from the structure $4d^45p$; $6s^4^2F$, 4P , 3G , $(4d^46s)$; and fragments of terms due to $4d^45d$. Zeeman effects of the majority of the lines have been measured and approx. g-values found for the low and middle sets of terms. The g-values depart largely from Landé's values, as do also the term intervals. Evidence is given that the term predicted by theory, $5s^3S(4d^45s)$, is present but it has not been fixed with respect to the other terms. The lowest term $4d^3D$ gives lines in the vacuum region and was found by H. E. White (Cornell) from plates taken there. The ionization potential is calcd. from the s^4F terms as 19.8 v. from $4d^3$ to $4d^4$. As in other spectra of this type there is some indication in the limits of the component series that the Hund theory of limits is incorrect. BERNARD LEWIS

4—ELECTROCHEMISTRY

COLIN G. FINK

Some new applications of electric furnaces. A. N. ORIS. *Am. Metal Market*, Magazine Sec. 35, No. 11], 6-8, 23(1928).—Several types of furnaces for Cu-brazing with protective atms. are described; also, furnaces for bright annealing steel. One of the latter is of the elevator type and is used for annealing sheet steel and punchings for motors and generators in a protective gas atm. Elec. furnaces are well suited for use in the nitriding process for case hardening. Low heat losses, accurate temp. control and suitability for long cycle heating operations are characteristics of elec. furnaces. Other applications of elec. heaters are: to heat pipes carrying hot liquids; for galvanizing pots, and for annealing steel wire in coils; for bread and cake baking; annealing glass products, etc.

W. H. BOYNTON

Heating elements for electric furnaces. G. I. LE BARON. *Chem. Met. Eng.* 35, 242-3(1928).—Formulas are given for calcg. the most economical dimensions for rectangular resistance units for elec. furnaces giving consideration to power rating and thermal loading. Examples are given.

C. J. BROCKMAN

Resistor thermal rating calculated. WALTER J. RYAN. *Elec. World* 32, 303 (1928).—A method is devised for the predetn., from a single run, of the temps. that may be reached in a given time with any current. The exptl. detns. are made on a resistor designed for the grounding of the neutral of an 11-kv. system. The test arrangements are shown and a Cu-constantan thermocouple and potentiometer placed in direct contact with the resistor ribbon. To est. the performance characteristic under different conditions, a formula is developed for a mathematical expression of the behavior of a current-carrying conductor: $TI\sqrt{h/k} \tan h(I\sqrt{kh}t)$, where T = temp. difference between conductor and ambient, t = time in secs. after start of load, h = heating const. depending on resistance and thermal capacity of element, k = cooling const. depending on radiation and convection characteristics, and I = resistor load in amps. In the case of one test run, as illustrated by curve, $T = 2.61 \tan h(1 \times 0.00001575 t)$. It is only necessary to make one temp. test to plot such a curve.

W. H. BOYNTON

The electrolysis of fused sodium hydroxide and of its mixtures with other metallic oxides. MAZZA LUIGI. *Atti congresso naz. chim. pura applicata* 2, 719-47(1926).—In the electrolysis of NaOH the electrode material is of prime importance. The 3 principal electrodes studied were Fe, Ni and Ag. Fe and Ni show extremely small change in wt. with diff.-current densities. The Fe electrode is easily polarized in comparison with that of Ni. The author's expts. with fused NaOH to some extent agree with the results obtained by Le Blanc and Brode, but differ with respect to the polarization values of the two electrodes as compared with the decompn. range. The expts. with mixts. of soda and SnO were more complicated than with NaOH alone. For the cathodic polarization there is an abrupt change at 0.80 v. which corresponds to that of H on Ni. The anodic charge rapidly drops to zero. The decompn. tension shows 3 points of deflection at 1.10 v., 1.50 v. and 1.95 v. The first and last are due to H and Na and the second is due to Sn. With fused NaOH contg. 5% lead oxide there is a sepn. of lead at the cathode. The cathodic decompn. tension shows a deflection at 1.10 v. and another more accentuated at 1.60 v. The results obtained with Cr are more complicated than with the preceding electrodes.

L. T. F.

Electrolysis in the manufacture of white lead. A. V. PAMFILOV AND V. S. IOFINOV. Ivanovo-Voznesensk Polytechnicum. *J. Chem. Ind. (Moscow)* 4, 803-7(1927).—Electrolysis should only be used for obtaining metallic Pb solns. from which white lead can be obtained by a pptn.; these 2 operations should not be combined in one. The authors' expts. were devoted to the study of the best conditions of electrolytic soln. of Pb as a preliminary operation in the manuf. of white lead by the pptn. method. The electrolytes used were chiefly NaOAc solns., sometimes chlorates, of 10% concn. With Pb anode in neutral solns. the c. d. should not be above 0.02 amp. per sq. cm., as otherwise the anode becomes covered by a black film; below 0.02 amp. the anode is brilliant and clearly cryst. In alk. solns. the c. d. should be lower to avoid darkening the anode and splitting off of O. Under normal conditions the soln. of Pb takes place with current yields close to 100%. The influence of the c. d. at the cathode is not so important. It is inconvenient to use either Pb or Fe cathodes, but almost any other metal can be used. A diaphragm has to be used, since at the cathode Pb seps. in an amount equiv. to that which dissolves at the anode. The use of unglazed earthenware or of cloth bags as diaphragms is unsatisfactory. It is much more convenient to use liquid diaphragms by means of formation of a double layer of the electrolyte, which is

attained thus: soon after the beginning of electrolysis a surface of sepn. is formed between the anolyte and the catholyte which must be maintained at one level and regulated by the addition of fresh electrolyte to the anode. *Electrolytic litharge* (PbO) produced by the action of the Pb dissolved at the anode on the alkali formed at the cathode (in a soln. of NaOAc or NaClO₃) precipitates. BERNARD NELSON

Electrolytic refining of the noble metals. F. CHEMNITTUS. *Chem.-Ztg.* 52, 385-8 (1928).—A brief discussion of the electrolytic refining of Au and Ag. C. J. B.

Electrolytic separation of copper from cuprous chloride solution. P. P. FEDOTIEV. *Z. anorg. allgem. Chem.* 173, 81-91(1928).—The soly. of CuCl in HCl and NaCl solns. is detd. and given as follows: with HCl in g./l. = 49.6, CuCl in g./l. = 11.1; with HCl = 182.9, CuCl = 121.9; with HCl = 256.0, CuCl = 217.7. Likewise with NaCl in g./l. = 9.3, CuCl in g./l. = 1.2; with NaCl = 80.2, CuCl = 12.3; with NaCl = 170.7, CuCl = 54.4; with NaCl = 369.8, CuCl = 298.3. In the electrolysis, electrolytic Cu is used as anode; for current density up to 100 amp./sq. meter, solns. with about 145 g. HCl or 240 g. NaCl and 40-50 g. CuCl per l. are used. Under these conditions a dense deposit is obtained. With higher current density (260 amp./sq. m.) the Cu seps. as crystals which do not adhere to the cathode. With other conditions equal, stirring the electrolyte gives a better deposit, but the current efficiency is less (83.5% for NaCl, 90% for HCl). Addition of 1 g. gelatin per l. gives a good deposit and increases current efficiency somewhat. The results show that it is possible to deposit Cu in a pure adherent coat from CuCl soln. with anodes of commercial material contg. Fe, Ni, Zn and Pb. H. STOERTZ

Cadmium plating in quantity production. C. H. LOVEN. *Metal Ind.* (N. Y.) 26, 252-5(1928).—L. points out the value of Cd as a rust preventive, and describes methods of plating and of analysis of Cd-plating solns. Precautions necessary to secure a silvery deposit with good corrosion-resistant properties are pointed out. A cyanide bath is used and means of maintaining the soln., and detg. Cd as metal in soln., and detg. total CN are noted. W. H. BOYNTON

Electrodeposition on aluminum. W. E. HUGHES. *Metal Ind.* (London) 32, 393-5, 441-3, 467-9(1928).—The adhesion of electrodeposits to Al and its alloys is discussed. The causes of adhesion between electrodeposits and base metals are classified as: (1) mechanical, (2) physical, (3) metallurgical. Cohesion is the paramount cause for the adhesion, with diffusion of the metal of less importance. Various theories are discussed, and the "alloy" view of the union between the deposits is discounted. Cohesion operates between the atoms of matter—between those of amorphous bodies as well as between crystals, and even between amorphous and crystal bodies. W. H. B.

A new achievement in galvanizing. F. W. YOUNG. *Ind. Eng. Chem.* 20, 686-7 (1928).—A description is given of the zinc plating of a steel drum 8 ft. 6 inches in diam. by 10 ft. 6 in. face. The drum was suspended and rotated in a trough contg. the plating bath made up of water 1 gal., Crown galvanizing salts 2 lbs., No. 1 toning salts 1 oz., No. 2 toning salts 2 oz. Pure horsehead zinc anodes were also contained in the trough. The drum was so mounted that only one fifth of its circumference dipped into plating bath. While the drum was rotated at 1 r. p. m. the surface was scratched with metal brushes. Ten amps. at 6 volts for 100 hrs. deposited 169 lbs. of zinc. A. W. C.

Effect of superposed alternating current on the deposition of zinc-nickel alloys. HERBERT C. COCKS. *Trans. Faraday Soc.* 24, 348-58(1928).—The electrolyte used is 0.5N ZnSO₄, 0.5N NiSO₄, 0.5N (NH₄)₂SO₄, 0.01N H₂SO₄, and the cathode is Pt. The expts. are conducted first with d. c., and then with superposed 40-50 cycle a. c. in which a. c.:d. c. = 0.46:1, 0.75:1, 1.61:1, 2.83:1, and 3.87:1, and curves are plotted giving % Ni in the deposit against d. c. density, and current efficiency for Ni, Zn and H against c. d. With d. c. only and a c. d. of 0.010 amp./sq. cm., the deposit contains about 95% Ni, but as the c. d. rises this falls slowly, being about 85% Ni at 0.015 amp./sq. cm., and then very rapidly, the deposit contg. only about 30% Ni at a c. d. of 0.020 amp./sq. cm. With a. c.:d. c. = 0.46:1, only 60% Ni is found in the deposit at 0.010 amp./sq. cm., decreasing to about 40% Ni at 0.015 amp. and about 30% Ni at 0.020 amp. As the ratio a. c.:d. c. rises, the proportion of Ni rises and does not fall off as rapidly as the c. d. increases. Thus with a. c.:d. c. = 2.83:1 the deposit contains about 70% Ni at 0.010 amp./sq. cm., 65% Ni at 0.015 amp., about 56% at 0.020 amp., and about 40% Ni at 0.030 amp. In the deposition of the alloy, when a. c.:d. c. = 0.75:1, there is a slight depolarizing effect due to the small anodic pulses, but with a. c.:d. c. = 2.83:1 the depolarizing effect is much greater and the retardation to Ni deposition is slightly reduced, especially below the "critical current density" of about 0.015 amp./sq. cm. Deposition potential-current density curves are also given and show a very rapid rise in cathode potential (E_H) at the "critical current density" when a. c.:d. c. < 2.83:1. Thus

with a. c.: d. c. = 0.75:1, e_H = 0.540 at 0.010 amp./sq. cm., 0.561 at 0.0125 amp./sq. cm. 0.765 at 0.015 amp., and 0.796 at 0.030 amp., while with a. c.: d. c. = 2.83:1, the values of e_H at the above c. ds. are 0.526, 0.547, 0.583 and 0.585. Expts. conducted with an a. c. frequency of 400-450 cycles/sec. and with a. c.: d. c. = 2.83:1 give 60.3% Ni in the deposit at 0.010 amp./sq. cm., 33.8% Ni at 0.020 amp./sq. cm., and 27.1% Ni at 0.030 amp./sq. cm. H. STOERTZ

Electrodeposition of iron-nickel alloys. S. GLASSTONE and T. E. SYMES. *Trans. Faraday Soc.* 24, 370-8 (1928).—In the electrodeposition of Fe-Ni alloys from mixed sulfate solns., the effect of boric acid as a buffer in place of AcOH is tested, as well as the influence of the addition of NaCl and $(NH_4)_2SO_4$ to the AcOH buffered electrolyte. Curves are plotted giving the variation in compn. of the alloys deposited at different c. ds., and are practically identical with those obtained for sulfate acetate solns. (C. A. 21, 3025). The effect of increased temp. upon the electrodeposition of Fe-Ni alloys from sulfate acetate solns. is studied. As at lower temps. (15°) the H-ion concn. has no influence on the relative tendencies of Fe and Ni to deposit in the form of an alloy. At 53 and 90° the rate of increase of the proportion of Fe in the deposit with increasing c. d. is much less than at 15°. The initial deposits and those contg. the max. amt. of Fe contain less Fe at 53° than at 15°. Thus when the electrolyte contains 2% Fe, the max. Fe content of the deposit is 22.6% at 15° and 14.9% at 53°, and when the electrolyte contains 70% Fe, the max. Fe content of the deposit is 93.5% at 15° and 86.5% at 53°. The influence of diln. and stirring is similar but not so marked at 53° as at 15°. At higher temps. the min. Fe content of the electrolyte from which the initial deposit contains less Fe than the electrolyte is lowered. H. STOERTZ

Research on the electrolytic reduction potentials of organic compounds. IV. Reduction potentials of nicotinic acid. MASUZO SHIKATA and ISAMU TACHI. *Bull. Agr. Chem. Soc. (Japan)* 3, 95-6 (1927); cf. C. A. 22, 720.—The reduction potential of nicotinic acid was measured with the dropping Hg cathode and polarograph. By comparison of observed reduction potential with the theoretical value, the first stage of reduction has been concluded to be the reduction of carboxyl group to aldehyde and the second stage of reduction is considered to be the reduction of pyridine ring by comparison with the reduction potential of pyridine. K. GOTO

Nickel plating practice in Cuba. E. G. LOVERING. *Metal Ind. (N. Y.)* 26, 260 (1928).—General discussion. W. H. BOYNTON

Chromium as a corrosion preventive. LESLIE WRIGHT. *Metal Ind. (London)* 31, 577; *Metal Ind. (N. Y.)* 26, 74 (1928).—A discussion of failures in Cr plate and their causes. It is found that the H content of the deposit varies approx from 1000 vols. in the true mat deposit to 2000 in the milky bright deposit. With increasing H content hardness increases. Photomicrographs of unetched deposits $\times 1000$ are shown, and indicate a steady decrease in grain size with increase in c. d. Hardness increases with decrease in grain size. Internal stresses produced in the deposition of Cr upon brass are largely overcome by annealing the deposit and brass at 300° for 1 hr. In the deposition of Cr, improved conditions are obtained by reducing the striking voltage to 8 v. and by complete immersion of the article previous to the application of the current. H. STOERTZ

Polish essential for chromium plate. CHARLES H. ELDRIDGE. *Iron Age* 121, 1680-2 (1928).—Details of successful methods for the prepn. of rough casting or stamping, the undercoat of Ni and the final Cr plate are given. Practical points are given about the polishing of the metal surfaces before Cr plating. Speed for the lathe: for grinding, 1200-1800 r. p. m.; for polishing, 1800-2200; for buffing, 2200-2700; and for chrome buffing, 2700-3000. Rough cast or forged steel needs a preliminary smoothing. Cr plate reproduces all surface defects, even exaggerating them in some cases. W. H. BOYNTON

A coal conductivity cell. ERIC SINKINSON. *Lehigh U. Ind. Eng. Chem.* 20, 862-5 (1928).—A cube of lump coal has different elec. cond. in different directions. The ohmic resistance of powdered coal can be measured with accuracy by using a specially designed cell in which the powdered coal may be subjected to pressure. Powdered coal with a resistance of 12,730 ohms was washed with concd. HCl to remove 1.47% of the sol. part of the ash; after this treatment the resistance was 9360 ohms. The method can be applied in sampling coal. The mesh for the most satisfactory and reproducible results is 48. The mechanics of operation and some precautions are given. C. J. BROCKMAN

Graphitic oxide as a depolarizer in the Leclanche cell. B. K. BROWN. *Trans. Am. Electrochem. Soc.* 53, (preprint) (1928).—In C. A. 22, 1107, the last sentence should read: Its gassing is very slight and the gelatinized paste does not swell much. C. J. B.

Electrical synthesis of hydrazine. G. BREDIG AND A. KOENIG. *Naturwissenschaften* 16, 493(1928).—By passing pure NH_3 gas through an intensely cooled high-tension arc and subsequent liquid air chilling hydrazine formation and detn. as benzalazine were made possible. From analogy with the process of catalytic HCN synthesis from CO and NH_3 , it is assumed that the reaction is caused by free imide formation: $\text{NH}_3 = \text{NH} + \text{H}_2$; $\text{NH} + \text{NH}_3 = \text{N}_2\text{H}_4$.

B. J. C. VAN DER HOEVEN

Electrolytic oxidation of formic acid. ERICH MÜLLER AND S. TANAKA. Dresden, Germany. *Z. Elektrochem.* 34, 256–64(1928).—In the oxidation of formic acid the anodic current voltage curves were detd. as before at a Rh-Pt anode in a divided cell contg. as the anolyte and catholyte a soln. of 10 mols. HCOOH and 1 mol. HCOONa . The pulsation of the current voltage curves continues for some time and then changes to a smooth curve. The explanation for this pulsation is that intermediate compds. are formed at the anode, which then undergo decompn.; equations explaining this are given in electronic form. The pulsations are between -0.2 and $+0.2$ v. on the hydrogen scale at the start with a smooth rise finally at $+1.2$ v. The first period of pulsation may be 155 sec. and the time shortens as the current increases. C. J. B.

The electrochemical oxidation of hydrocinnamic acid. FR. FICHTER AND RUDOLF SENTI. Anstalt anorg. Chem. Basel. *Festschrift A. Tschirch* 1926, 410–4; *Chem. Zentr.* 1927, II, 54–5; cf. C. A. 21, 2260.—Among other products, hydrocinnamic acid (I) at the anode yields phlorotinic acid (*p*-hydrocoumaric acid) (II) which is also prepd. from phlorhizin. I is partially dissolved and partially suspended in 2 *N* H_2SO_4 and is electrolyzed in a Pb electrolytic cell coated with PbO_2 , with an anodic current d. of 0.004 amp. per sq. cm. A Pb stirrer serves as cathode. At the termination of the expt. the liquid is made alk. with Na_2CO_3 and is extd. with Et_2O . The alk. soln. yields a mixt. of quinone (III), hydroquinone and perhaps acetophenone. After the alk. soln. is exhausted, it is acidified with dil. H_2SO_4 and again extd. with Et_2O . The ext. is fractionally distd., whereby EtCO_2H , unattacked I, II and diphenolic condensation products of high mol. wts are obtained. $(\text{CH}_2\text{CO}_2\text{H})_2$ was isolated from the aq. liquor after extn. with Et_2O . A scheme of reactions is derived, according to which an OH first enters the *p*-position in the side chain of the I mol., with formation of II. Further oxidation seps. the side chain, with formation of III and EtCO_2H . III is then partially decompd. to maleic and fumaric acids, from which $(\text{CH}_2\text{CO}_2\text{H})_2$ is formed at the cathode. II as a phenol is responsible for the condensation, and it is conceivable that in the highest fractions a di-*p*-hydrocoumaric acid, formed from 2 mols., remains behind, which cannot be distd. without decompn. In further expts. the Kolbe hydrocarbon synthesis was studied. I and PCl_5 form hydrocinnamyl chloride, b_p 177–9°. The latter in AcMe treated with ice-cold Na_2O_2 soln. yields the peroxide of I, m. 37°, explodes at 130°. Its explosive decompn. through heating yields α,δ -diphenylbutane, m. 52°. C. C. D.

Electrochemical behavior of silicate glasses. III. Cathode and anode gases. M. J. MULLIGAN, J. B. FERGUSON AND J. W. REBBECK. *J. Phys. Chem.* 32, 779–84 (1928); cf. C. A. 22, 1526.—A photographic record of the disappearance of cathode gas upon the reversal of the current is reproduced. In the presence of NaOH , H_2 will disappear into the glass. The disappearance is probably due to the formation of water which is resorbed by the glass. No gas is formed when the Na is replaced by Ag. In some cases Ag does not completely replace Na in the glass. 1.2 v. is considered a higher e. m. f. than is necessary for the production of cathode gas. Anode gas was obtained at 275° by using soda-lime glass with 110 v. This is a lower temp. than previously reported for anode gas. IV. Solid electrolytic deposits. *Ibid* 843–51.—When soda-lime glasses were electrolyzed with Hg as anode and then as cathode for a shorter period of time a brown deposit appeared. They are very minute spots under the microscope. Further electrolysis produced rings and patches, always at least 1 or 2 microns below the surface. With well-annealed glass very fine, uniformly distributed spots obtained. This deposit was shown to be Si. With Ag as the anode and cathode a crystalline deposit, which was shown to be Ag, was obtained. When the direction of the current is reversed the glass is punctured, Na is liberated at the puncture, reacts and deposits Si which may build up a deposit at the punctured surface. This phenomenon explains the slowness of gas reappearance due to the fact that Na is used up, before reaching Hg.

ARTHUR FLRISCHER

Joffé's studies on electric breakdown strength. P. JORDAN. *Naturwissenschaften* 16, 460–2(1928).—A review of Joffé's recent work (C. A. 22, 518) on the mechanism of insulation breakdown.

B. J. C. VAN DER HOEVEN

Breakdown of spark gaps. J. SLEPIAN. *Elec. World* 91, 761(1928).—The great speed of breakdown of spark gaps at atm. pressures observed exptly. contradicts sharply the classical Townsend theory of sparkover, which calls for 10^{-5} sec. To solve this S.

suggests that the thermal ionization of the gas takes place in the single passage of an electron from cathode to anode, and before the T. process can develop. Calculation, taking the space-charge into account, confirms this view. Sparkover takes place at those gradients which produce thermal ionization, and good agreement is obtained between breakdown gradients calcd. on this basis and those observed exptly. The "suppressed discharges" figures of Torok (*Trans. Am. Inst. Elec. Eng.* 1928), which are difficult to explain otherwise, are a natural consequence of the theory of S. The time for breakdown with moderate overvoltages is of the order of 10^{-7} sec.

C. J. BROCKMAN

Puncture tests affected by strength of oil. J. T. LITTLETON, JR. AND W. W. SHAVER. *Elec. World* 91, 759(1928); cf. *C. A.* 21, 3836.—Expts. were made to det. the effect of the dielec. strength of oils on the puncture voltage of an insulator under oil (1) in air at a pressure of 60 lb. per sq. in., (2) in special steam-treated oil up to the potential used in (1), and (3) in regular insulating oil. Potentials ranged from 100 kv. to 205.5 kv. Dielec. failure took place at a much lower potential under regular oil than in air under pressure and under steam-treated oil. Results seem to show that the puncture of an insulator in regular insulating oil is preceded by a breakdown of the oil, which is instrumental in causing the puncture.

C. J. BROCKMAN

Economics of corona loss. J. T. LUSIGNAN, JR. Leland Stanford Univ. *Elec. World* 92, 405-7(1928); 6 illus.—Known facts regarding corona as developed by Ryan and Peek are reviewed. It is necessary to carry the investigations into the field of economic voltage range of power transmission.

Electric battery with liquid depolarizer. A. SCHMID. Brit. 281,698, Dec. 2, 1926. One electrode comprises a container made of a metal such as Cr-Ni-steel or "leaded Al" which is not attacked by the electrolyte. A Zn electrode is supported in the container from a screw rod in the cover. The electrolyte may contain Mg or Al salts to diminish the production of ppts. The depolarizing liquid may contain a weak acid or a salt such as borax to diminish the production of free H. The battery is put into operation by inversion and may serve as a flashlight battery. Various structural features are described.

Dry cell electric batteries. NAAMLOOZE VENNOOTSCHAP ELEMENTENFABRIEK UTRECHT BATTERY CO. Brit. 282,578, March 22, 1927. Structural features.

Dry cell electric batteries. EDMUND B. WHEELER and JAMES C. WRIGHT (to Western Elec. Co.). U. S. 1,680,656, Aug. 14. In order to preserve dry cells without dissipation of energy, they are maintained at temps. below 10° .

Storage battery. CARL J. DUNZWEILER (to Willard Storage Battery Co.). U. S. 1,680,038, Aug. 7. Structural features.

Storage battery. H. F. JOEL. Brit. 281,770, Sept. 9, 1926. Structural features.

Storage battery. A. POUCHAIN. Brit. 282,449, Dec. 20, 1926. Negative electrodes may be formed of silvered brass, partially covered with Zn and varnished over the remaining portion. Structural features are specified.

Storage batteries. ALFRED BLAUSZTAIN. Fr. 634,609, May 18, 1927. The plates are made up of a series of surfaces in zigzag form.

Storage batteries. SILICA GEL CORPORATION. Fr. 634,479, May 16, 1927. The plates are of an active material with which is incorporated silica gel.

Storage batteries. SILICA GEL CORPORATION. Fr. 634,480, May 16, 1927. The spaces between the positive and negative elements are filled with silica gel.

Storage battery separators. P. MALLON. Brit. 282,100, Dec. 11, 1926. Structural features.

Box for electric batteries. WARREN E. GLANCY. U. S. 1,679,657, Aug. 7. A box of molded asphaltic compn. is provided with bail-receiving grommets of hard rubber and fiber.

Battery and accumulator. RAYMOND MOLET. Fr. 634,017, May 7, 1927. An app. combining the qualities of a battery and an accumulator comprises a positive rechargeable element formed of an alloy of Pb and Sb and carrying a paste of minium, litharge and powdered pumice made with H_2SO_4 , and a negative element of Zn amalgam in a tank made of ebonite or similar substance.

Electric accumulators. COMPAGNIE GÉNÉRALE D'ÉLECTRICITÉ. Fr. 634,076, May 9, 1927. The pole of an accumulator and the vessel surrounding it contg. oil or fat are made in two sep. pieces which are joined by sliding one on the other or by screwing or soldering. Cf. C. A. 22, 3359.

Pole for electric accumulators. COMPAGNIE GÉNÉRALE D'ÉLECTRICITÉ. Fr. 634,260, May 5, 1927. Details of construction.

Electrodeposition of tin. VULCAN DETINNING CO. Fr. 634,225, April 13, 1927. In the electrodeposition of tin, a compd. of tin which is insol. in water but sol. in the products of the electrolysis is added to the bath to maintain the supply of tin ions. Such a compd. can be prepd. by treating an alkali stannate with a suitable acid to neutralize the alkali of the stannate.

Electrodeposition of zinc. URLYN C. TANTON. Fr. 634,080, May 9, 1927. See Brit. 280,103 (C. A. 22, 2890).

Electroplating with chromium. J. C. PATTEN. Brit. 282,337, Dec. 20, 1926. Various mech. features and details of c. d. are specified in connection with the Cr plating of recessed articles, tire molds, etc. Parts nearest the anode may be blocked off (suitably with copal varnish or nitrocellulose lacquer) while recessed parts are plated during the first portion of the plating operation. Pb anodes conforming to the shape of the article may be spaced from it about 0.5–1.5 in. Cr-plated molds are not affected by vulcanization and tires are easily removed from them without need of employing lubricants. If desired, tire molds may be formed wholly of Cr or a Co-Cr alloy.

Copper-plating cylinders of rotary printing apparatus. H. KUPPEL and L. SIMÉANT. Brit. 282,274, May 10, 1927. Cylinders are prepd. for reuse by polishing to remove all ink and then electroplating in a bath formed of $CuSO_4$ 18, H_2SO_4 4 and water 78%, using Cu sheets as anodes and a temp. of 30–45° and a c. d. of 0.4–0.5 amp. per sq. cm. and periodically reversing the current. The c. d. is diminished near the end of the operation, to produce a hard deposit of fine grain.

Electrolytic generation of oxygen and hydrogen. G. F. JAUBERT. Brit. 281,674, Dec. 1, 1926. A diaphragm suitable for use in electrolysis of alk. solns. comprises material such as perforated sheet metal, wire gauze or asbestos cloth carrying a coating and filler of a hydrogel of an org. or inorg. colloid such as may be formed by dipping the material in a soln. of $MgCl_2$ or $MgSO_4$ and then in a Na silicate soln. The colloid may also be deposited on the diaphragm by a preliminary electrolytic treatment. When Na_2CO_3 or K_2CO_3 is used for the electrolyte, a hydrogel of Mg hydrocarbonate may be used, and among the other colloids which may be employed are: Fe silicate, kaolin, $Fe(OH)_3$, natural or artificial yellow ochre, limonites, clays, Mg or Al phosphates, graphite, C from blood, rubber, hydrates of alk. earth or rare earth metals, and Cu, Ni or other metal in flocculent form. When not in use the diaphragm may be dipped in a 50% glycerol soln. to prevent it from drying.

Electrolytic rectifier. EDGAR W. ENGLE (to Fansteel Products Co.). U. S. 1,680,210, Aug. 7. Ta and Pb electrodes are used with an electrolyte of dil. H_2SO_4 soln. contg. a small quantity of Co sulfate.

Metallic electrodes. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 634,574, Sept. 22, 1926. Electrodes are cut directly from metal foil in the shape of a rectangle having a narrow strip perpendicular to one of the sides of the rectangle, the strip acting as the current collector.

Electrodes suitable for use in production of aluminum. ÉLECTRO MÉTALLURGIQUE DE MONTRICHER. Brit. 282,672, Dec. 21, 1926. Electrodes are formed in sections bolted to each other and to rings. Other structural features also are specified.

Cell with conical electrodes for electrolysis of water to produce oxygen and hydrogen under high pressure. J. E. NONGGERRATH. Brit. 282,688, Dec. 21, 1926.

Self-baking electrodes for electric furnaces. JENS WESTLY (to Det Norske Aktieselskab for Elektrokemisk Industri of Norway). U. S. 1,679,284, July 31. Electrodes are made with a mantle of material such as Al and with internally projecting ribs of another compn. such as an alloy of Al with 10% Fe. Cf. C. A. 21, 3028; 22, 920.

Combined electrode and stirring device for electric resistance furnaces. STANLEY A. W. OKELL (to Industrial Chemical Co.). U. S. 1,680,630, Aug. 14. Gas such as reducing or oxidizing gas may be introduced into the reaction chamber through openings carried by a rotating disk-shaped device or electrode so that the gas serves to stir the material in the chamber.

Electric furnace and apparatus for tilting it. SAMUEL ARNOLD, 3RD. U. S. 1,680,237, Aug. 7.

Electric induction furnace. PORTER H. BRACE (to Westinghouse Elec. & Mfg. Co.). U. S. 1,680,407, Aug. 14. Structural features.

Electric resistance furnace. GEORGE M. LITTLE (to Westinghouse Elec. & Mfg. Co.). U. S. 1,680,422, Aug. 14. Carbonaceous electrodes are mounted so that their abutting ends are pressed together continuously and oxidation of the electrodes when traversed by elec. current is restricted mainly to their junction by projecting a jet of air adjacent their ends.

Electric resistance furnaces. M. MCGUINNESS. Brit. 281,837, Nov. 3, 1926. A stationary, tilting or rotating elec. furnace for roasting ores such as cinnabar has heating elements of Ni-Cr wires embedded in MgO and encased in malleable iron or steel and is provided with devices for assisting the travel of the material through the furnace. Various structural features are described.

Resistance-heated electric crucible furnace and associated apparatus for casting metals. KRAFTMETALL AKTIEHOLAGET. Brit. 282,047, Dec. 7, 1926.

High-frequency electric induction furnace. HIRSCH, KUPFER- UND MESSINGWERKE A.-G. Brit. 282,656, Dec. 23, 1926. The charge is arranged as tightly as possible within a metal vessel which fits inside the crucible and which may be formed of wire or strip and of the metal that is to be melted.

Electric furnaces for bright-annealing of metal articles. WILHELM ROHN (to Siemens-Schuckertwerke G. m. b. H.). U. S. 1,678,875-6, July 31.

Device for feeding materials to electric furnaces. PAUL L. J. MIGUET (to Soc. Electrometallurgique de Montricher). U. S. 1,680,163, Aug. 7.

Pyroelectric separation of materials such as mica and sand. GUSTAV A. OVERSTROM. U. S. 1,679,740, Aug. 7. The material is heated and dried and, after electrification by pyro-electric action, is passed over a stationary support of glass and allowed to fall from the surface in such a manner that sepn. of the mica from the rest of the sand is effected. U. S. 1,679,739 relates to similar processes. Both pats. describe app.

Apparatus for measuring the current density in a galvanic bath. PAUL E. BOURGEOIS. Fr. 634,333, May 13, 1927.

Detectors for electric waves. SIEMENS-SCHUCKERTWERKE A.-G. Brit. 281,720, Dec. 6, 1926. A layer of metal such as Cu with a surface coating of oxide or other compd. of the metal is used in contact with a pointed electrode such as steel, brass, Sn or C.

Composite electrical conductor. FRANK F. FOWLE. U. S. 1,679,518, Aug. 7. Elec. conductors such as wires, plates or bars are formed with an inner layer of Cu, an outer body of steel contg. at least 0.30% chemically combined C and a bonding layer of steel or Fe which prevents alloying action between the main mass of steel and Cu during pouring of the metals in the manuf. of the conductor.

Loaded electric cables. W. S. SMITH, H. J. GARNETT and J. A. HOLDEN. Brit. 282,504, Sept. 25, 1926. The loading wire or tape is spaced from the conductor by wire or the like which is fusible at a temp. not exceeding the annealing temp. An alloy of Ag 60 and Cu 40% may be used. The loading strip is preferably slightly oxidized to prevent sticking to the spacing wire during annealing.

Sheathing for alternating current electric cables. FELTEN & GUILLEAUMS CARLSWERK A.-G. Brit. 281,709, Dec. 3, 1926. Losses due to induced currents are reduced by employing a sheathing of an alloy of Pb with over 5% of Bi and Sb. Cf. C. A. 21, 222.

Gas-tight seal for high-power vacuum tubes or other electrical devices. ALBERT W. HULL (to General Electric Co.). U. S. 1,680,738, Aug. 14. See Brit. 270,345 (C. A. 22, 2296).

Electric resistance heater unit. JAMES C. WOODSON (to Westinghouse Electric & Mfg. Co.). U. S. 1,680,404, Aug. 14. Structural features.

Heavy-duty electric resistance heater. EDWIN L. WIGAND. U. S. 1,678,838, July 31. Structural features.

Apparatus for making small electric lamp bulbs from short pieces of glass tubing, etc. GENERAL ELECTRIC CO., LTD. Brit. 282,057, Dec. 9, 1926.

Filaments for electric incandescent lamps. J. A. M. HAWADNER (to Soc. française

des lampes a incandescence Luxor). Brit. 281,685, Dec. 1, 1926. Refractory filaments such as those of W are provided with a light-emitting surface of metal of lower m. p. such as Mo, covered with lime, MgO or the like.

Electric incandescent lamps. P. A. CAMPBELL (to British Thomson-Houston Co., Ltd.). Brit. 282,066, Dec. 9, 1926. Helical filaments are mounted upon the bulb stem before the mandrel is removed; the mandrel may be dissolved out with a mixt. of HNO₃ and H₂SO₄, and supporting wires or other parts exposed to the action of the acid may be formed of W, Ni, chrome-Ni or chrome-steel. The preliminary heat treatment of the filament to set it may take place before or after removing the mandrel.

Electric incandescent and arc lamps. GENERAL ELECTRIC CO., LTD. Brit. 282,043, Dec. 7, 1926. A solid NH₄ halide is used in gas-filled lamps and decomposes when the lamps are in use to form a mixt. of H and a volatile halogen compd. as used as described in Brit. 248,680 (C. A. 21, 709). The NH₄ halide may be placed in a vessel having a capillary opening and located in the exhaust tube in the foot of the lamp bulb. Brit. 282,044 specifies bulbs with internal reflectors of refractory metal or alloy, the reflecting efficiency of which increases with the temp., e. g., W, Ta, Mo or their alloys.

Improvements in arc-lamps. SOC. ANON. ANCIENS ETABLISSEMENTS BARBIER, BÉNARD ET TURENNE. Fr. 633,944, May 5, 1927.

5—PHOTOGRAPHY

C. E. K. MEES

Practical digest of the year's work in photography. E. J. WALL. *Am. Annual of Phot.* 42, 187-97(1928).—In the review of progress in photography, the following subjects are covered: phototherapy and emulsions, amateur cinematography, development and fixation, optical and color sensitizing, after-treatment methods, motion picture work, special processes (bromoil, carbonyl, etc.), photolithography and color photography.

Short-wave radiation in the service of photography. H. C. JAQUET. *Phot. Kor.* 64, 203-5(1928).—Examples are given of portraits taken by the ultra-violet radiation (filtered) from an elec. projection lamp.

Dependence of the resolving power of a photographic material on the wave-length of light. O. SANDVIK AND G. SILBERSTEIN. *J. Opt. Soc. Am.* 17, 107-15(1928).—The resolving powers of six various emulsions have been investigated. The spectral region extends from wave length 380 mμ toward the red end of the spectrum as far as the sensitivity of the particular emulsion would permit. The resolving power has a max. value at wave length 380 mμ, decreasing rapidly in the blue-green to a min. value at about wave length 535 mμ. The change in resolving power with wave length corresponds approx. with the change in the absorption coeff. with the wave length in the spectral region investigated.

Parallelism of constant density curves using varying times of exposure. E. F. M. VAN DER HELD AND B. BAARS. *Z. Physik* 54, 364-8(1927).—H. and B. exposed fast plates over a time range of 1:1000 and found no variation from parallelism of density curves using rodinal developer.

Restoring daguerreotypes. E. KUCHINKA. *Phot. Kor.* 63, 367-70(1927).—The risk of ruining a daguerreotype in attempting its restoration by the usual technic (involving the use of a soln. of KCN) is much greater when the support has been silvered by rolling with foil than when it was silvered by electroplating. The method that has been used can be detd. by examn. with a magnifying glass.

Reversal process. A. REYCHLER. *Am. Phot.* 22, 113(1928).—If an exposed plate is treated with an oxidizing soln., flashed to light, and physically developed with Hg a positive of good quality can be obtained.

Riken reversing developer. HIROMU ISHIDŌ. *Bull. Inst. Phys. Chem. Research (Tokio)* 7, No. 3, 30(1928).—A positive is obtained by first development with a special solution, then bleaching, and finally redeveloping. It is claimed that the "Riken" developer, of which the composition is not given, produces less fog than metol-hydroquinone and can be used for high-speed emulsions as well as for low speed. It is stated that γ obtained by the reversal process is 1.85 for either special rapid or process plates, but that if the first developer is lowered in concentration to one-quarter, a γ of 1.35 is obtained.

Contribution to the Herschel effect. E. PETERL. *Phot. Kor.* 64, 205-6(1928).—P. shows how the Herschel effect ("red rays undo the action of white light," as Abney

expresses it) may assume practical importance when making prints on gaslight papers, if the exposed sheets are allowed to remain unduly long in the red light of the darkroom before development.

E. R. BULLOCK

Color fog as substance of image on a new lantern-slide plate. O. PARESCH. *Phot. Korr.* **64**, 165-7(1928).—P. refers in particular to the *Farb-Diapositiv* plate recently put on the market by the firm of Lainer & Hrdliczka in Vienna. He points out that the color of a developed image depends solely on the phys. constitution and size of the Ag grain; and considers that the colored images obtained with the above-mentioned plate for example, and the recommended NH_4OH -contg. developer are identical with dichroic fog.

E. R. BULLOCK

Role of electrolytes in the peptization of the silver of a negative. G. SCHWARZ. *Phot. Korr.* **64**, 207-11(1928).—On the basis of the Pauli theory of charged ionogen complexes, S. would expect that peptization of the Ag of photographic negatives by boiling (under the exptl. conditions prescribed by Lüppo-Cramer) would necessarily fail to occur in the absence of alkalis. After the latter have been removed by the most careful electrodialysis, he finds this expectation capable of exptl. proof. The role of alkali consists in the extraordinary acceleration of the breaking down of glutin, the resulting glutoses and peptones forming the mother substance for the charged ionogen complexes. When the gelatin is broken down by prolonged heating in the absence of alkalis there is finally produced a sol of acidoid character.

E. R. BULLOCK

Printing on development paper. B. T. J. GLOVER. *Am. Annual of Phot.* **42**, 9-14(1928).—A simple exposition of the fundamental principles underlying the making of prints on chloride, bromide, and chloro-bromide papers. The Watkins factorial system is advocated for detg. development times on the latter two papers. An analysis of print failures is included.

G. E. MATTHEWS

Method for the proportional reduction of excessive contrast in bromide and gaslight prints. H. KESSLER. *Phot. Korr.* **64**, 197-200(1928).—The print is partially bleached in a not too concd. $\text{K}_3\text{Fe}(\text{CN})_6\text{-KBr}$ soln., then darkened in Na_2S soln. or in Se "Carbon" toner, and finally treated with Farmer's reducer to remove the unaltered Ag. (It would seem difficult to secure proportional reduction by such a method — *Abstr.*)

E. R. BULLOCK

Direct sulfur toning. A. HERZ. *Camera* (Luzern) **6**, 288-9(1928).—Bromide prints are toned by transferring them from the fixing bath to a warm, dil. "hyposoln." contg. a few drops of H_2SO_4 . The prints are rubbed with cotton in the wash H_2O to remove pptd. S. Incompletely sulfided prints take on a brighter color, even after drying, if subjected to steam to complete the toning, or if treated with Farmer's reducer to remove unchanged Ag.

E. R. BULLOCK

Toning with selenium. C. BOSNJAK. *Phot. Korr.* **64**, 223-4(1928).—A short account is given of a modification of "bleach-and-sulfide" toning in which a relatively small quantity of Se is added to the Na_2S soln. It is pointed out the Se which seps. from the bath when not in use may be re-dissolved in fresh sulfide soln. The Se bath gives a superior tone, practically permanent, with many gaslight papers.

E. R. B.

Ultramicroscopic observations of Ag bromide crystals (SCHAUM, KOLH) 3.

EDER, JOSEF MARIA: *Die Photographie mit dem Kollodiumverfahren. Nasses und trockenes Kollodiumverfahren, Bromsilber- u. Chlorsilber-Kollodium-Emulsion.* 3rd ed., revised and enlarged. Halle (Saale): W. Knapp. 354 pp. Ausführl. Handbuch d. Photographie Bd. II. Tl. 2. M. 17.20; bound, M. 19.20

Color photography. MICHELE MARTINEZ. Fr. 634,073, May 9, 1927. Color photographs are taken at a single exposure in the ordinary way on a compd. negative formed of 3 superimposed layers or sections having emulsions of different rapidity and different color sensitivity and without the necessity of color filters. The positives are printed on compd. sensitive material comprising 3 layers which print out in the desired colors, and require only washing after printing and are superimposed to produce the finished print. Cf. C. A. **22**, 2891.

Multi-colored cinematographic and photographic films. JOHN E. THORNTON. U. S. 1,679,694-5, Aug. 7. Mech. features.

Photographic film. FRANK F. RENWICK (to du Pont-Pathé Film Mfg. Corp.). U. S. 1,680,635, Aug. 14. Nitrocellulose films are backed with a compn. comprising a cellulose ester and a protein compn., e. g., cellulose nitrate and acetate and gelatin. U. S. 1,680,636 specifies non-static cinematographic film with a backing comprising a

water-insol. protein material such as casein and which may also contain cellulose nitrate or acetate.

Recovery of silver from cinematographic films. CHARLES PERROT. Fr. 633,685, Sept. 6, 1926. Ag is recovered from old films by removing the gelatin layer with NaOH, warming with HCl to ppt. the gelatin, which is filtered, dried and reduced.

Sensitive photographic surfaces. MICHELE MARTINEZ. Fr. 634,074, May 9, 1927. Sensitive layers which print out in red, blue and yellow comprise for red a deriv. of urea such as alloxan, alloxanic acid, alloxantin or murexide either alone or with metallic salts; for blue, a mixt. having ferric salts as its basis along with a cyanide or ferri-cyanide; and for yellow, silver lactate and metallic oxalates and ferric salts, and preferably an excess of lactic acid. Formulas are given for prepg. solns. of the sensitizers.

Drying colloidal layers on photographic plates and films. M. ZIPPERMAYR. Brit. 281,700, Dec. 2, 1926. Drying and hardening are effected at a temp. above the m. p. of the layers, preferably *in vacuo*. Glycerol may be used to prevent curling of films during the drying.

Increasing sensitiveness of photographic emulsions. SAMUEL E. SHEPPARD (to Eastman Kodak Co.). U. S. 1,678,832, July 31. Sensitiveness of photographic materials is increased by the addn. of very small proportions of substances such as the salt of ethyl dihydroxythiocarbonate as prepd. by Debus (*Ann.* 72, 1; 75, 121), the "mustard oil oxides" obtained by the action of Br on mustard oils, or isothiocyanates (Freund, *Ann.* 235, 14), thiurets or benzoyldisulfide. Diselenides or ditellurides of the same general character also may be used instead of the disulfides.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Chlorides of ruthenium. H. GALL AND G. LEHMANN. Munich Techn. Hochschule. *Ber.* 61B, 1573-6(1928); cf. *C. A.* 21, 711.—Comment upon the paper by H. Remy and A. Lührs (*C. A.* 22, 2521). The reduction of Ru^{IV} to Ru^{III} is disputed, the blue soln. obtained being attributed to Ru^{II}. H. STOERTZ

The fractionation of mixtures of neodymium and samarium. L. ROLLA AND L. FERNANDES. *Atti accad. Lincei* [6], 7, 370-2(1928).—An examn. of curves in which the soly. is a function of the at. nos. of the rare earths shows a max. difference of soly. for the double Mn nitrates. The method of Lacombe, which is based on the crystn. of these salts, is satisfactory only for sepg. the intermediate fractions, i. e., for the purification of Pr and Nd and *vice versa*. Crystn. of the Sm fractions as double Mn nitrates is impossible because of their great soly. An attempt was therefore made to reach the correct degree of soly. by crystg. solid solns. of double Mg nitrates with double Mn nitrates. Two materials of different origin and compn. were used. (1) Nd oxide contg. Sm as impurity, from the initial crystn. with the bromate method. The oxide was converted into nitrate and equal quantities of Mg(NO₃)₂ and Mn(NO₃)₂ were added. Thirty series of crystns. from 6 fractions eliminated completely the Sm in the last 2 while abs. pure Nd was obtained in the first 4 fractions. Mn was concd. in the end fractions and Mg in the initial fraction. (2) Nd oxide contg. Pr and all the Sm originally present, from the end fractions of the fractionation of double nitrates of NH₄ and Tl. In this case the Mn was added in decreasing proportions from the initial to the end fractions and *vice versa* for addns. of Mg. After 15 series on 12 fractions, the last end fractions acquired a yellow color characteristic of Sm, and contained only a little Nd. After a new series of 50, all Sm was accumulated in the last 4 fractions, the last 2 contg. no Nd and only traces of Tb and Yt earths. The third from the last contained almost equal quantities of Nd and Sm, and the fourth from the last contained only Sm. Pr was recovered in the first 2 fractions still contg. a little Nd, and this was in an abs. pure state in 5 middle fractions. The method is therefore very satisfactory. C. C. DAVIS

The action of aluminum, ferrous and ferric iron and manganese in base-exchange reactions. O. C. MAGISTAD. Arizona Agr. Expt. Sta., *Tech. Bull.* 18, 445-63(1928).—Expts. with neutral and acid solns. of Fe and Al salts on artificial zeolites showed that the replaceable base previously present was released. The residue usually contained no H-zeolite, nor did ferric Fe or Al enter the zeolite complex in such a manner as to be replaced by other replacing agents subsequently used. Chem. analyses of zeolites before and after treatment with AlCl₃ in EtOH showed that there was no addn. of Al or marked loss of Al or Si. Similar trials with FeCl₃ in H₂O and EtOH showed that Fe took the place of Al in the zeolite. This reaction was almost complete in the EtOH

expt., the zeolite residue contg. practically no Al. The substitution did not take place in equiv. quantities. Soils and artificial zeolites treated with Al or ferric-salt solns. until the solns. remained acid and the previously held zeolitic bases had been removed lost all base-exchange capacity. The decrease in base-exchange capacity of zeolites and soils is a function of the concn. of the ferric Fe or Al salt solns. used. Ferrous Fe as FeSO_4 was found to be readily exchangeable for Ca in a zeolite and in soils. A small quantity of $\text{Fe}(\text{OH})_2$ was pptd. in the zeolite in addn. and a larger quantity in soils. The ferrous Fe replacing the Ca is itself replaceable by Ba salts. Mn as MnCl_2 and MnSO_4 replaced Ca in both zeolites and soils. Some pptn. of $\text{Mn}(\text{OH})_2$ occurred in both cases. The Mn replacing Ca is itself replaceable by Ba salts. The reaction equation for MnSO_4 and the particular Ca zeolite used was detd. The equation was of the same type as that for the usual base-exchange reactions. If the property of base-exchange is to be considered a factor in plant feeding, destruction of base-exchange capacity in soils by Al-contg. salts, or other means, may result in serious consequences. A bibliography is appended.

C. R. FELLERS

Effect of alkalinity on basic cupric sulfates. O. A. NELSON. U. S. Bur. of Chemistry and Soils. *J. Phys. Chem.* 32, 1185-90(1928).—There are described in the literature at least 30 basic cupric sulfates, in which the $\text{CuO}:\text{SO}_3$ ratio varies from 10:1 to 2:1, with diff. amts. of H_2O of hydration. The information in regard to these compds. is indefinite and contradictory. N. undertook to prep. a series of basic cupric sulfates in which it could be shown that the concn. of the SO_3 or the OH in the product was a continuous function of the ratio of the Cu salts and alkali used in the prepn. The stock solns. were 0.5 M CuSO_4 and M CO_2 -free NaOH. Twenty or 40 cc. of the CuSO_4 soln. was used in each expt., but before the addn. of NaOH the portions were dild. to a concn. of 0.01 M. The NaOH was dild. to the equiv. concn., and both solns. were cooled to below 5° . The CuSO_4 soln. was stirred violently during the addn. of the NaOH. The stirring was then continued for about 2 hrs., the temp. being kept between 0° and 5° . The CuSO_4 soln. was stirred violently during the addn. of the NaOH. The stirring was then continued for about 2 hrs., the temp. being kept between 0° and 5° . The flocculent ppts. were allowed to settle, the p_{H} of the supernatant liquid was detd., and the ppts. were analyzed. Plotting the results gave curves which did not show a series of distinct breaks as would be expected if a no. of true chem. compds. had been formed. The product represented by the vertical portion of one of the curves has an approx. formula of $7\text{CuO} \cdot 2\text{SO}_3$. The constancy of compn. of this product over a fairly wide range of concns. indicates that it is a true chem. compd. Any product with a Cu: SO_3 ratio of 3.5 to 1.0 or over may be prepd. by addn. of the proper quantity of base. The results indicate that the compns. of basic cupric sulfates as prepd. in the lab. depend on the method of prepn. and the ratio between the reacting substances.

LOUISE KELLEY

Precipitation of copper with sodium thiosulfate. M. G. RORER. *Tids. Kemi Berg.* 7, 94-5(1927).—Pptn. of Cu with $\text{Na}_2\text{S}_2\text{O}_3$ is complete in the presence of HNO_3 , HCl or H_2SO_4 . The Cu_2S is washed with cold H_2SO_4 soln.

B. C. A.

Optically active copper compounds. W. WAHL. *Soc. Sci. Fennica Commentationes Phys. Math.* [14], 4, 1-5(1927).—Diethylenediaminediaquocupric tartrate has been prepd. from Ba tartrate and the complex sulfate which is obtained when aq. solns. of CuSO_4 and ethylenediamine are mixed and evapd. to dryness. After filtration from BaSO_4 the Cu complex salt is pptd. by the addn. of alc. to the soln. The salt has $[M] +28.3^\circ$. After two extns. with alc. the residual compd. has $[M] -59.4^\circ$. When obtained by vacuum evapn. of the aq. soln., the salt has $[M] -38.3^\circ$, and of the residue after alc. extn. -134° . The *l*-diaquodiethylenediaminecupric ion must have $[M]$ at least 190° . A series of optically active iodides has been prepd. from the tartrates. Ni yields corresponding tartrates of varying activity, the highest observed value being about $+420^\circ$.

B. C. A.

Spacial configuration and rotatory dispersion in optically active cobalt and rhodium salts. F. M. JAEGER AND H. B. BLUMENDAL. Groningen Univ. *Verslag Akad. Wetenschappen Amsterdam* 37, 421-34(1928).—J. and B. replace 1, 2 or 3 ethylenediamine mols. in salts of the triethylenediamino cobalt-type by the same no. of 1,2-diaminocyclopentane mols. They record the changes occurring in the rotatory dispersion...

A. L. HENNE

The hydrates, transition temperatures and solubility of sodium iodate. H. W. FOOTE AND JOHN E. VANCE. Yale Univ. *Am. J. Sci.* 16, 68-72(1928).—Solns. contg. NaIO_3 were analyzed by adding an excess of KI, acidifying with H_2SO_4 and titrating with $\text{Na}_2\text{S}_2\text{O}_3$, or by detg. the H_2O in the residue by heating at $120-40^\circ$. Only two stable hydrates are found in soln., $\text{NaIO}_3 \cdot 5\text{H}_2\text{O}$ (I) and $\text{NaIO}_3 \cdot \text{H}_2\text{O}$ (II). Below 19.85°

I is stable; at this transition temp., I and II are in equil. From 19.85° to 73.4° II exists; at the higher temp. II and NaIO₃ are in equil. Solubilities were detd. at a given temp. by approaching equil. from supersatd. and under-satd. solns., after the mixts. had been shaken in a thermostat for 4–6 hrs. From the logarithmic curve, the soly. of II can be represented between 20° and 49.9° by: $\log \text{ soly.} = 3.6344 - (802.8/T)$; that of I between 0° and 15° by: $\log \text{ soly.} = 7.7793 - (2019/T)$. The f. p. of a satd. soln. of NaIO₃ is -0.35°.

J. BALOZIAN

The nature of Prussian blue. DAVID DAVIDSON and LARS A. WELO. Rockefeller Inst. Med. Research. *J. Phys. Chem.* 32, 1191–6 (1928).—Recently Reihlen and Zimmermann (*C. A.* 21, 3324) have proposed a constitutional formula for sol. Prussian blue in which the 2 Fe atoms are combined in the form of a complex polynuclear ion. Neither the cond. measurements in soln. nor the magnetic measurements in the solid state, as made by D. and W. on compds. of this type, have produced any evidence of the existence of the postulated polynuclear ion.

LOUISE KELLEY

The preparation of potassium and sodium tetrabismuth tartrates. PHILIP A. KOBER. *J. Lab. Clin. Med.* 12, 962–7 (1927).—Contrary to previous directions, alk. solns. of tartaric acid dissolved Bi(OH)₃ more efficiently at a low temp. When the reaction is allowed to go to completion, tetrabismuth tartrates result, instead of tribismuth tartrates as has been heretofore assumed. Two new compds., Na and K tetrabismuth tartrate, are described and the processes given for their prepn. Preliminary results indicate that these new tetrabismuth tartrates are much less toxic than other Bi tartrates isolated heretofore. Certain data given indicates if they do not prove, that the so-called tribismuth tartrates, mostly heretofore used in syphilitic therapy, are only mixts. of tetra- and dibismuth tartrates. Preliminary expts. show that the Na tetrabismuth tartrate can be put up in an aq. soln. and administered intramuscularly.

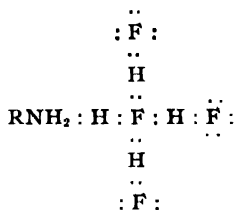

ETHEL W. WICKWIRE

Addition compounds of halides of bivalent metals and organic bases. VI. G. SCAGLIARINI and E. BRASI. Univ. Bologna and Univ. Ferrara. *Atti accad. Lincei* [6], 7, 509–11 (1928); cf. *C. A.* 21, 2623 and *Accad. sci. med. nat. Ferrara* Apr. 3, 1927.—The following addn. compds. of Cd salts and hexamethylenetetramine were prepd. in water and in acetone, the first time that addn. compds. of the latter and Cd salts have been described. All were cryst. $2\text{CdCl}_2 \cdot \text{C}_6\text{H}_{12}\text{N}_4$ is prepd. by adding aq. $\text{C}_6\text{H}_{12}\text{N}_4$ (not too concd.) to aq. CdCl_2 (also not too concd.) and washing the ppt. repeatedly. $\text{CdBr}_2 \cdot 2\text{C}_6\text{H}_{12}\text{N}_4$ and $\text{CdI}_2 \cdot 8\text{H}_2\text{O} \cdot \text{C}_6\text{H}_{12}\text{N}_4$ were prepd. in the same way. $\text{CdCl}_2 \cdot \text{C}_6\text{H}_{12}\text{N}_4$ is prepd. by adding a cold, concd. acetone soln. of $\text{C}_6\text{H}_{12}\text{N}_4$ very slowly to a cold, concd. acetone soln. of CdCl_2 and washing repeatedly with acetone. $3\text{CdBr}_2 \cdot 2\text{C}_6\text{H}_{12}\text{N}_4$ is prepd. by adding $\text{C}_6\text{H}_{12}\text{N}_4$ in acetone to cold concd. CdBr_2 in acetone, ceasing the addn. of $\text{C}_6\text{H}_{12}\text{N}_4$ when the sepn. of needle crystals can be detected microscopically. If on the other hand concd. CdBr_2 in acetone is added to concd. $\text{C}_6\text{H}_{12}\text{N}_4$ in acetone so that there is a deficiency of CdBr_2 , then the compd. $\text{CdBr}_2 \cdot \text{C}_6\text{H}_{12}\text{N}_4$ is pptd. The latter is also formed by mixing hot equimol. solns. of CdBr_2 and of $\text{C}_6\text{H}_{12}\text{N}_4$ in acetone. $2\text{CdI}_2 \cdot \text{C}_6\text{H}_{12}\text{N}_4$ is prepd. by adding a cold, satd. soln. of $\text{C}_6\text{H}_{12}\text{N}_4$ in acetone to a cold satd. soln. of CdI_2 in acetone and washing repeatedly with acetone.

C. C. DAVIS

The hydrofluorides of organic bases and a study of hydrofluoric acid. J. F. T. BERLINER and RAYMOND M. HANN. U. S. Bur. Chemistry. *J. Phys. Chem.* 32, 1142–62 (1928).—The HF derivs. of PhNH₂, *o*-, *m*- and *p*-toluidine, *m*- and *p*-nitroaniline, *m*-xylydine, cymidine, ψ -cumidine, *o*-tolidine, Ph₂NH, triphenylguanidine, *p*-phenetidine, *o*-anisidine, *p*-nitro-*o*-anisidine, α - and β -C₁₀H₇NH₂, iodo-*o*-toluidine, anthranilic acid, PhNHMe, PhNH₂Et, metanilic acid and sulfanilic acid were prepd. The analyses of these compds. in every case indicated the deriv. to be of the type B.4HF, where B represents an aliphatic or aromatic primary, secondary or tertiary base. The diamines gave derivs. of the type R(NH₂)₂.(4HF)₂. Compds. of this general compn. were prepd. in dil. and concd., hot and cold aq., ethereal and alc. solns. of HF. The method used was to add 0.4 to 0.7 mols. of pure 48% HF directly to the base or to an Et₂O or Me₂CO soln. contg. 0.1 mol. of the purified base. On cooling, the HF compd. sepd. in nearly quant. yields. The only hydrofluorides which gave characteristic m. ps. were those of *m*-nitroaniline (m. 207–9°, cor.), *p*-nitroaniline (m. 173–4°, cor.), anthranilic acid (m. 217–8°, cor.) and PhNH₂Et (m. 170–1°, cor.). Attempts were made to titrate solns. contg. known quantities of these hydrofluorides with NaOH, indicators with transformations in several ranges of *p*_H being used. When an indicator having a range above a *p*_H of 6 was used only $\frac{3}{4}$ of the combined acid could be titrated. Varying the temp., concn. of salt and of alkali, solvent and indicators used gave the same result. These results and those of electrometric titration studies indicate that one of the HF mols. of the (HF)₄ complex is combined in a manner diff. from that of

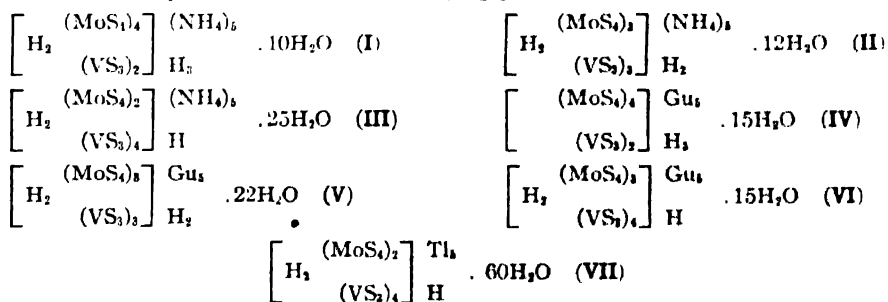

the other 3. On the basis of a consideration of the nature of both inorg. and org. compds. of HF, B. and H. suggest the following structure for the compds. of HF with org. bases:

The lack of agreement between the results of B. and H. and those of Weinland and his collaborators (*Z. anorg. Chem.* **45**, 39(1905) and *C. A.* **2**, 1436 disappears when one examines the data of the latter. In a no. of cases the formulas assigned by W. to the compds. prep'd. were based upon titration values with 0.1 *N* alkali. As B. and H. have shown, such titration allows the estn. of only $\frac{1}{4}$ of the combined HF. Moreover, several of the preps. described by W. were not prep'd. in the presence of an excess of HF, as were those of B. and H.

LOUISE KELLEY

Investigations of thio salts. VI. Molybdovanadothioaquaates. L. FERNANDES. *Atti accad. Lincei* [6], **7**, 496-501(1928); cf. *C. A.* **22**, 736.—Thiomolybdovanadates were synthesized by satg. an aq. soln. of the thiomolybdate with H_2S , adding the thiovanadate in very dil. NH_4OH , passing through H_2S for several hrs. until an iridescence appears, letting stand until the salt is completely pptd., and washing with EtOH and Et_2O . Water decomps. these salts rapidly. With too much H_2S or with insufficient alky. the salts become contaminated with amorphous by-products. The NH_4 salts are the only ones which can be synthesized directly and the other salts are prep'd. by double decompn., the NH_4 salt being added to a concd. soln. of the other salt, e. g., guanidine chloride or TiNO_3 . The NH_4 salts are unstable and liberate H_2S and free S, while the guanidine and Ti salts are relatively stable. The following new microcryst. compds. were prep'd. (Gu signifying guanidine):

I is black with maroon reflection, II black, III black with violet reflection, IV dark maroon, V violet-black, VI dark violet and VII dark violet.

C. C. DAVIS

Constitution of hydrazoic acid and its esters. HANS LINDEMANN and HANS THIELE. Braunschweig Techn. Hochschule. *Ber.* **61B**, 1529-34(1928).—This is an effort to det. whether the constitution of the derivs. of HN_3 , such as the azido esters, is

represented by the ring formula $\text{RN}:\text{N}:\text{N}$ or the formula $\text{RN}:\text{N}:\text{N}$. This is accomplished by calcn. of the *parachors* of these esters, given by the expression $P = [M/(D - d)] \cdot \gamma^{1/4}$, in which M is the mol. wt., γ the surface tension, D the density of the liquid and d the density of its vapor. D is det'd. by means of a pycnometer, and γ is measured in an app. constructed in the Techn. Hochschule Berlin. *Me azidoacetate* (I), *azidoacetone* (II), *phenyl azide* (III), and *o*-(IV) and *p*-(V) tolyl azides are exam'd., and the following values obtained for P . For I 277, II 220.9, III 267.3, IV 303.8, V 307.0. Calcn. of P for the 2 formulas given above, in which values for the double bond and the triple bond between N, are based upon values obtained for C:C, C:O, C:S, N:O and C:N, give figures for the first formula which agree very well with the exptl.

results. Thus in the case of I, P calcd. from the ring formula is 276.3 and calcd. from the $N:N$ formulas is 306.2, while the exptl. result is 277. Two other formulas have been suggested: $R-\text{N}-\text{N}\equiv\text{N}$ and $R-\text{N}=\text{N}=\text{N}$; P calcd. for the first of these is 281.4 and for the second 281.2, both for the azidoacetic ester. The constitution of these esters is therefore best represented by the formula $\text{RN}:\text{N}:\text{N}$. H. STOERTZ

The system alumina-water (HÜTTIG, WITTGENSTEIN) 2.

7—ANALYTICAL CHEMISTRY

W. T. HALL

Remarks on "the magnitude of errors of observation in chemical analysis," by F. Goudriaan. A. J. KORVEZEE AND N. H. J. M. VOOGD. *Chem Weekblad* 25, 242-7 (1928); cf. *G. C. A.* 22, 1295.—The accuracy of chem. analysis must be calcd. by making use of the mean square error of the measurements themselves. Several detailed examples are given.

Recommended specifications for analytical reagent chemicals. Citric and tartaric acids, alcohol 95 per cent and absolute, calcium chloride, anhydrous, magnesium chloride, methanol, potassium ferricyanide, potassium ferrocyanide, sodium bisulfate fused, sodium chloride, zinc chloride. W. D. COLLINS, H. V. FARR, JOSEPH ROSIN, G. C. SPENCER AND EDWARD WICHERS. *Ind Eng. Chem.* 20, 979-83 (1928); cf. *C. A.* 22, 553.

Analysis of dilute solutions by the opacity of fine suspensions formed in such solutions. A. BOUTARIC AND M. LLE. G. PERRÉAU. *Rev. gén. colloïdes* 6, 113-7 (1928).—See *C. A.* 22, 1747.

Capillary analysis. R. DUBRISAY. *Mon. prod. chim.* 9, No. 90, 4-7 (1927); cf. *C. A.* 21, 660.—The vol. of 40 drops of 1/600 N NaOH soln. (free from carbonate), dropped from a constricted tube into "vaseline" oil contg 1% of oleic acid, was 1.20 cc., while if to the soln. an equal vol of 1/800 or 1/80 N NaCl soln. was added, the vol. of 40 drops was 0.98 or 0.20 cc. The method should be applicable to the detn of alkali halide in 0.0002 M soln.

Drop reactions. F. FEIGL. *Mikrochem.* 6, 50-62 (1928).—A claim for priority. Many of the drop reactions recently described by Tananaev and his co-workers (*C. A.* 19, 1108; 21, 545; *Z. anal. Chem.* 72, 155-7 (1927)) had been described by Feigl and his co-workers several years previously.

Radioelements as indicators. F. PANETH. *Nature* 120, 884-6 (1927); *Science Abstracts* 31A, 192.—A brief summary of P.'s investigations on the use of radioelements as indicators in chem. investigations with the common elements. P. rightly anticipates that the method will become more commonly used the more familiar the advantages of the method become to non-radiologists. The method is based on the isotopic behavior of certain radioactive bodies with the ordinary elements. Thus Th C is chem. inseparable from Bi and consequently, once added to Bi, it always sticks to Bi through all possible chem. reactions. Th C is easily detected and measured by means of ordinary ionization app. (electroscopes, etc.), and it may therefore be used to indicate the presence, or otherwise, of Bi in a particular prepn. Other valuable methods of using the isotopic property are outlined in the paper, and a table is given showing the various radioactive indicators and their common isotopic elements. An application of Th C-Bi is suggested in therapeutics—to measure the proportion of Bi stored in the body, etc. The applications are very numerous.

Spectrophotometric determination of hydrogen-ion concentrations and of the apparent dissociation constants of indicators. V. Fast green F(C)F. W. C. HOLMES AND E. F. SNYDER. *Bur. of Chemistry and of Soils. J. Am. Chem. Soc.* 50, 1907-10 (1928).—Spectrophotometric data for the detn of the H-ion concn. for p -hydroxyeroglucine A are given over the range pH 6.7-10.0. The tetra-Na salt is colorless, the tri-Na salt is blue with an adsorption band at approx. 611 $m\mu$, and the di-Na salt is green with a band at 628 $m\mu$. Its apparent dissoc. const. is 8.1 at 29°. D. H. P.

Methods for the determination of hydrogen-ion concentration. KARLO WEBER. *Archiv. hem. farm.* 2, 146-57 (1928).—A review of the electrochem. and colorimetric methods used for the pH detn. with bibliography.

New methods for quantitative spectral analysis of metals. WALTHER GERLACH.

Z. Metallkunde 20, 248-51(1928).—A summary is given of exptl. results obtained by G and E Schweitzer. For the detn. of a small quantity of impurity, say Pb in Au, there are 5 methods given which do not depend upon the use of ultimate rays, as recommended by de Gramont. (1) Take photographs on the same plate under the same elec. and light conditions of the sample and of specimens contg. known amts. of the impurity. Then by comparing the intensity of certain lines caused by the impurity it is possible to det. 0.002-1% of Pb in Au within 10% of the truth. (2) Compare the intensity of lines caused by the impurity with certain lines of the pure substance. Then by means of an empirical table the % of impurity can be detd. (3) If there are no homologous lines suitable for such a comparison, the difficulty can sometimes be overcome by making a photograph of the spectrum of some other metal on the same plate. (4) For detg. Pb in Au another method is available which depends upon comparing Pb lines with lines produced by an alloy of 9 parts Cd to 1 part Sn, using different times of exposure for getting the spectrum of this alloy. When the desired lines of the Sn are of equal intensity with those of the Pb, it is possible to tell by comparing certain Au lines with those of the Sn, what the % of Pb is. (5) By increasing the temp. it is possible to intensify the lines of the more volatile element. Thus by melting the electrodes, 0.02% of Pb in Au gives the appearance of 3% of Pb at a lower temp. W. T. H.

Volumetric determination of antimony in presence of lead, tin and copper. A. VASSILIEV AND W. KARGIN. *Papers Pure Appl Chem Karpov Inst., Bach Festschr.* 1927, 143-56.—The reaction (Gvory): $\text{KBrO}_3 + 3\text{SbCl}_3 + 6\text{HCl} = 3\text{SbCl}_5 + \text{KBr} + 3\text{H}_2\text{O}$, using as indicator methyl orange, which is decolorized by excess of bromate, is employed. When the liquid contains PbSO_4 , low (1-3%) values are obtained; the soln. is therefore siphoned off, the PbSO_4 dissolved in concd. HCl , and the diluted soln. titrated with bromate. The presence of Sn does not affect the results. Low (0.3-1.7%) values are obtained in presence of Cu. In presence of Pb and Cu 96-97% of the Sb is found; treatment of the ppt. (as above) indicates a further 2% of Sb. With the pure metals, but not with technical alloys, tartaric acid is not oxidized by the bromate. B. C. A.

Volumetric estimation of copper and zinc. S. L. ROBERTON. *Roy. Tech. Coll. Met Club J.* 1927-8, No. 6, 37-40.—The reactions involved in the volumetric estn. of Cu by both the iodide and cyanide titration methods, and of Zn by titration with a soln. of $\text{K}_4\text{Fe}(\text{CN})_6$ are discussed. DOWNS SCHAAF

Determination of lead in Babbitt metal. G. V. SHESTAKOV. *J. Chem. Ind. (Moscow)* 4, 907-8(1927).—Heat 1 g. of finely divided alloy with 20 cc. of aqua regia in an Erlenmeyer flask which has a small funnel in its neck. After about 15 min. when the alloy is all dissolved, add 50 cc. of 10% citric acid soln. and neutralize to phenolphthalein with 20% NH_3 soln. If any PbCl_2 ppts., dissolve it by heating. Pour the soln. into a l. beaker, add 5 cc. of 60% AcOH , dil. to 500 cc. and heat to boiling. Into the boiling soln. introduce dropwise 20-30 cc. of 5% $\text{K}_2\text{Cr}_2\text{O}_7$ soln. and continue heating until the ppt. is heavy and cryst., which may require 30-60 min. Cool to below room temp., filter through a Gooch crucible, wash with 3% AcOH twice and once with 10% NH_3 soln. Heat to const. wt. Det. Cu in a sep. sample using the method of Walker and Whitman, *C. A.* 3, 2659. BERNARD NELSON

The determination of manganese in iron and steel by the silver nitrate-persulfate method. S. V. LIPIN. *Z. anal. Chem.* 72, 401-16(1927).—The journal reference was given incorrectly in *C. A.* 22, 1301. H. G.

Determination of small quantities of sodium. WEILAND. *Mitt. Kali-Forsch.-Anst.* 1927, 21-8.—Manipulative details are given for the method preferred, viz., the pptn. of Na^+ by a concd. uranyl Mg acetate soln. forming $3(\text{UO}_2)(\text{C}_2\text{H}_3\text{O}_2)_4 \cdot \text{Mg} \cdot (\text{C}_2\text{H}_3\text{O}_2)_2$, $\text{NaC}_2\text{H}_3\text{O}_2 \cdot 9\text{H}_2\text{O}$, which is practically insol. in alc. B. C. A.

A modification of Schneider-Finkener's method for the determination of zinc. IGNACIJ MAJDEL. *Arhiv. hem. farm.* 2, 127-36(1928).—Neutralize a dil. H_2SO_4 soln. contg. 0.2-0.3 g. Zn with ammonia using Congo-paper as indicator. Add 8 cc. 0.5 N H_2SO_4 , dil. to 300 cc. and introduce H_2S (2 bubbles per sec.) at 70°. After one hr., filter, wash and ignite in a Rose-crucible with S in a stream of H_2 . J. K.

Bromometric determination of chlorates. K. PETERS AND E. DEUTSCHLÄNDER. *Apoth.-Ztg.* 41, 594-5(1926).—The chlorate (0.05 g. ClO_3) is dissolved in 0.1 N arsenite soln. (25 cc.) and dil. HCl (10 cc.) and gently boiled for 10 min. after addn. of KBr (0.05-0.1 g.); the soln. is then diluted to about 100 cc. and titrated hot (methyl orange being used) with 0.1 N KBrO_3 soln. until colorless. B. C. A.

Electrometric determination of chromic acid in the presence of vanadic acid with the aid of induction and catalysis. RUDOLF LANG AND JOSEF ZWEŘINA. *Z. Elektrochem.* 34, 364-7(1928).—Zintl (*C. A.* 22, 556) has published a method for the detn. of

Cr and V in the presence of one another, but his method will give good results only when the V content is low. It is possible to solve the problem with larger quantities of V present if MnSO_4 is used as inductor and a trace of I as catalyzer. In this case the titration can be accomplished in *N* acid solns., whereas Z's method requires at least 25% of acid. Unless the inductor and catalyzer are present, the titration is tedious and the reduction potential of a little chromic acid is the same as that of considerably more vanadic acid. There are 3 ways in which it is recommended to work, the last one probably being the most convenient in actual practice. (1) Carry out the titration of the chromate with 0.1 *N* arsenite soln. in *N* HCl in the presence of 0.4 g. of MnSO_4 until the potential, which rises at first, begins to fall, then add a drop of 0.0025 molal KI or KIO_3 and finish titrating dropwise, until there is a marked drop in potential. (2) Add the catalyzer before beginning the arsenite titration. This method, which applies also to the titration of very small quantities of Cr, requires in a total vol. of 100 cc. 5–7 cc. of concd. H_2SO_4 and 10 cc. of concd. HCl. In the neighborhood of the equivalence point it is necessary to titrate very slowly. (3) First carry out a preliminary detn. of the Cr by adding an excess of arsenite soln. and the catalyzer, then KMnO_4 until an excess is shown by the color of the soln. and finally arsenite soln. to the electrometric end point. Then for the detn. of both Cr and V, make the soln. *N*–2*N* in H_2SO_4 , add 1–2 g. of NaCl or 2–5 cc. of concd. HCl, and 0.4 g. of MnSO_4 . Add at least 80% of the requisite vol. of 0.1 *N* arsenite soln., wait 2 min. to make sure that it has been entirely oxidized by the chromate anion, then add 1 drop of the catalyzer and titrate slowly to the potential break. Methods (2) and (3) can be carried out with simple reference electrodes consisting of Pt dipping in *N* HCl or 2 *N* H_2SO_4 and a little dissolved $\text{K}_2\text{Cr}_2\text{O}_7$. For the analysis of a soln. contg. Fe, Cr and V, and this is of practical interest, first make sure that the soln. is fully oxidized by adding H_2O_2 or HNO_3 to the HCl or H_2SO_4 soln. Then neutralize with soda until a permanent ppt. begins to form, add 60–70 cc. of 0.1 *N* KMnO_4 and heat at a vol. of 200–250 cc. until the soln. just begins to boil. Now add 3–5 cc. of 0.1 *N* AgNO_3 , 30 cc. of 5 *N* H_2SO_4 and 20 cc. of 6 *N* HCl. After a few min. all the higher oxides of Mn will be reduced. Boil until all Cl_2 is removed and the AgCl is well coagulated. Cool, make the acidity correct and titrate the $\text{Cr}_2\text{O}_7^{--}$ with arsenite according to one of the methods given above and the V by the method of Kelley and Conant (*C. A.* 10, 2179). This requires a fairly high acid concn. in order to get a marked potential change at the end point. It seems best, therefore, to add 5–10 cc. of sirupy H_3PO_4 , which makes the end point sufficiently distinct although by no means as marked as when considerable acid is present.

W. T. H.

Comparison of volumetric methods for determining chromates. P. I. SOKOLOV AND T. V. ARISTOV. *J. Chem. Ind. (Moscow)* 4, 905–6(1927).—Of the 3 common methods of titrating chromates, the iodometric method is too expensive for factory control, since it requires 4–5 g. KI per 0.1 g. $\text{K}_2\text{Cr}_2\text{O}_7$. Penny's method, in which the chromate is treated with an excess of FeSO_4 , and the excess of the latter is titrated with standard $\text{K}_2\text{Cr}_2\text{O}_7$ soln. must be carried out by dropping the chromate into the soln. of FeSO_4 , and not vice versa, as otherwise great errors may result. Schwarz's method, which is the same except that the final titration is made with standard KMnO_4 soln., is as exact as Penny's method.

BERNARD NELSON

The assay of phosphoric acid. F. A. MAURINA. Parke, Davis and Co., Detroit. *J. Am. Pharm. Assoc.* 17, 668–71(1928).—A specimen of H_3PO_4 was assayed by the molybdate method, finally weighing as $\text{Mg}_3\text{P}_2\text{O}_7$. The variations in 4 detns. were 85.57–85.67%. Four other methods including the U. S. P. X were used with unsatisfactory results. The substitution of $\text{Zn}(\text{OH})_2$ for ZnO in the U. S. P. X method gave satisfactory results. The results in 4 detns. were 85.57–85.62%.

L. E. WARREN

The microchemical determination of phosphoric acid as strychnine phosphomolybdate. C. ANTONIANI AND R. B. JONA. Reale Istituto Superiore Agrario Milano. *Giorn. chim. ind. applicata* 10, 203–5(1928).—The method of Embden, which involves the addn. of a reagent (prepd. by mixing a HNO_3 soln. of $(\text{NH}_4)_2\text{MoO}_4$ with strychnine nitrate) to the soln., thus pptg. strychnine phosphomolybdate (cf. *Z. physiol. Chem.* 113, 138), gives very satisfactory results. In the course of the expts. it was found that the ppt. may be allowed to settle and stand for some hrs. without influencing the results; that an excess of reagent does not vitiate the results, though the best conditions are with 6 parts of strychnine and the corresponding quantity of nitromolybdate soln. per 1 part of P_2O_5 ; that an excess of HNO_3 or of other free acid does vitiate the results; and that org. and mineral salts are without influence. The same results are obtained in the detn. of H_3AsO_4 . The method is the most sensitive of gravimetric methods, and is of special value for detg. P_2O_5 in soils, in superphosphates, in Thomas slag, and in animal

and vegetable products. One mg. or even less of P_2O_5 can be detd. precisely.

C. C. DAVIS

The ceruleo-molybdate method for determination of phosphates. V. P. GREEN-STREET. *Malayan Agr. J.* 16, 70-5(1928).—Denigés' colorimetric method, which depends upon the formation of a blue color when an acid soln. of H_3PO_4 is treated with molybdate and stannous ions, was applied to the analysis of tapioca tubes, stems and leaves, oil palm leaflets, pineapple ash and Serdang soil, materials contg. 0.1-5.0% of P_2O_5 , and found to give results which were, on the whole, fairly satisfactory. If the soln. is too acid and contains dissolved SiO_2 , the results are likely to be low.

W. T. H.

Determination of combined water in natural sulfates. O. ŠEBELÍK. *Chem. Obzor* 2, 46-9(1927).—Minerals contg. alunite lose water at 350° upwards, complete elimination being effected only at white heat. Sources of error are discussed; the methods of Kurizianov and of Dittrich give good results.

B. C. A.

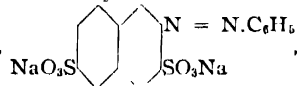

Uranyl acetate as a reagent in microscopic qualitative analysis. E. M. CHAMOT AND H. A. BEDIET. *Mikrochemie* 6, 13-21(1928).—In applying the uranyl acetate test for Na the best procedure consists in evapg. the soln. to be tested on a microscope slide until a dry film is formed, placing a drop of the reagent close to the edge of the film, and drawing a platinum wire through the drop, thence across the film. The formation of isotropic tetrahedra indicates the presence of Na; fine clusters of hair-like crystals the presence of the alk. earths or of Pb; tetragonal prisms K, Rb, Cs, Ag, Tl or NH_4 , square plates Ba and orthorhombic plates or prisms Mn, Mg, Zn, Cd, Fe (ferrous), Ni, Co or Cu. The presence of Na together with a member of the last-named group results in the sepn. of monoclinic triple acetates in the form of polysynthetic twins of somewhat indefinite chem. compn. In the absence of metals other than alkalis the formation of Na Zn uranyl acetate is probably the most sensitive test for the presence of Na; so sensitive is this reaction that silica object slides should be used to avoid possible contamination from Na of the ordinary glass slide.

B. C. A.

Colorimetric determination of small quantities of aniline. V. I. MINAEV, K. O. SVETLYAKOV AND S. S. FROLOV. *J. Chem. Ind. (Moscow)* 4, 840-2(1927).—The for-

mation of the blue dyestuff,

, can be used as a sensitive

test for aniline. Absorb the aniline in H_2SO_4 , if it is desired to det. aniline in air, cool the acid soln. with ice, add an excess of alkali nitrite and allow to stand 30-45 min. Treat the diazo soln. thus obtained with a slight excess of $NaHCO_3$, add an excess of H-acid and allow to stand 10-15 min. Compare the color with that obtained with known amts. of aniline in a colorimeter. This test is applicable to as little as 0.02 mg. of aniline in 100 cc. of soln.

BERNARD NELSON

Determination of anthracene and anthraquinone. H. PIRAK. *Z. angew. Chem.* 41, 231-3(1928).—In the original Höchst method the results obtained are too low on account of over-oxidation; the modified method of Sielisch (C. A. 21, 721) gives low results through incomplete oxidation, and a slight excess of CrO_3 soln. over the amt. indicated by them is necessary for accurate results. The time required for the detn. may be shortened by dilg. the hot H_2SO_4 soln. of anthraquinone with boiling H_2SO_4 . Loss by sublimation may be high at 110° in the original Höchst test (cf. Sielisch, C. A. 21, 721) but is reduced by use of the crucibles advocated by Jacobsohn (C. A. 20, 3145). A lower temp. is, however, preferred. In the procedure recommended, anthracene (1 g.) is dissolved and oxidized as in Sielisch's method, a further 1 cc. of the chromic acid soln. being added when the soln. is definitely brown. After cooling and dilution with 400 cc. of ice-cold water, the anthraquinone is collected on a Jena glass filter-crucible, washed as in Jacobsohn's method, and dried at $95-100^\circ$. The contents are then transferred to a glass beaker and heated with 10 cc. of H_2SO_4 monohydrate at 105° (boiling brine-bath) for 20 min.; acetic acid (25 cc.), free from traces of reducing impurities and previously heated to 100° , is added. On cooling, the anthraquinone seps. as a white lump at the bottom of the beaker. When the contents reach room temp., the beaker is placed in ice for 20 min. and 200 cc. of cold water are then added, rise of temp. being avoided by occasionally cooling in ice. The anthraquinone is collected on the original filter, washed as before and dried at $95-100^\circ$ to const. wt., after which it is sublimed at $180-200^\circ$ (1 hr.) in a drying oven. The door of the oven is not completely closed, and the stopper carrying the thermometer is notched to allow of a slight air-current. The detn. is complete in 4-5 hrs., and gives satisfactory results with

technically pure anthracene and anthraquinone, and with crude anthraquinone. With mixts. contg. less than 50% of anthraquinone the method gives low results for anthraquinone and consequently high values for anthracene. B. C. A.

Detection of hydrocyanic acid. N. A. ROOZENDAAL. *Pharm. Tijdschr. Nederl.-Indie* 4, 110-3; *Chem. Zentr.* 1927, II, 143.—In the Prussian blue test, the least possible alkali, preferably $\text{Na}_2\text{CO}_3 + \text{NaHCO}_3$ according to Kolthoff, should be used. The thiocyanate test is sometimes disturbed in toxicological work by thiocyanates that are likely to be present in corpses. The nitroprusside test is not sensitive enough; the picric acid, guaiacol resin, phenolphthalein, fluorescein, benzidine and pyrimidone tests are not definitely characteristic. Of these last, the fluorescein test is to be recommended. All these reactions are carried out better in soln. than with paper strips. The decolorization of I-starch by HCN is not characteristic. The AgCN reaction is discussed. C. C. DAVIS

Determination of organic carbon in soil and in pure organic compounds by means of permanganic anhydride. LUIGI UMBERTO DE NARDO. *Stazione Chimico-Agraria Sperimentale Udine. Giorn. chim. ind. applicata* 10, 253-5(1928).—The method is very precise; in fact it gives results almost identical with those obtained by elementary analysis. The app. is simple, a detn. requires only 20-30 min., the reagents are cheap, and altogether it is preferable to elementary analysis or the $\text{Ag}_2\text{Cr}_2\text{O}_7$ method, particularly for soils. Add 5 cc. of H_2SO_4 (concd. for org. compds. and 30% concn. for soils) to the sample (0.2-0.4 g. of soil, or 0.1-0.2 g. of org. compd.), then add 10 cc. of a soln. of KMnO_4 in concd. H_2SO_4 (1 g. per 10 of acid), heat, absorb the CO_2 in 50% aq. KOH and calc. from this latter absorption the % C. With calcareous soils, the carbonate CO_2 must first be eliminated by treatment with H_2SO_4 . Complete absorption of CO_2 is assured by the passage of a CO_2 -free air current through the system. In the prepn. of Mn_2O_7 it is very important to avoid the formation of oily drops of free Mn_2O_7 on the H_2SO_4 because of the danger of ignition. Thoroughly dry KMnO_4 , cold, concd. H_2SO_4 , slow prepn. of the reagent and the use of only fresh solns. will avoid this danger. C. C. DAVIS

Determination of halogens in organic compounds. M. PRONER. *Roczniki farm.* 4, 99-106(1926).—The method is specially suitable for naphthalene derivs., terpenes, and heterocyclic compds. The substance (0.1-0.2 g.) is slowly warmed with 95% alc., and small pieces of Na (1 g.) are added; the mixt. is warmed with 30% H_2O_2 soln. (5 cc.) until evolution of O ceases, acidified with HNO_3 , reduced with Na_2SO_3 , warmed and the chloride pptd. with AgNO_3 . B. C. A.

Micro-determination of mercury in organic compounds and the determination of carbon and hydrogen in such compounds. A. VERDINO. *Mikrochemie* 6, 5-12(1928).—The destruction of the org. matter by heating with concd. H_2SO_4 and HNO_3 leads to a small loss of Hg, but good results are obtained by heating for 2 hrs. at $250-270^\circ$ with fuming HNO_3 in a sealed tube. The Hg can be obtained from the soln. by electrolysis with 2.5-3.2 v., a gold-plated Pt gauze cathode being used. B. C. A.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

Determinative mineralogy. IV. P. C. PUTNAM, E. J. ROBERTS AND D. H. SELCHOW. *Am. J. Sci.* 15, 455-60(1928); cf. C. A. 22, 2529.—The reagent for testing Au was 1 vol. of pyridine in 9 vols. of 40% HBr. A minute fragment of the mineral was

treated with aqua regia (4HCl to 1 HNO₃) on a glass slide and evapd. to dryness, the residue was taken up with water, again evapd. to dryness and again dissolved in water. A portion (small drop) of this soln. was transferred to another part of the slide beside an equal vol. of the reagent. These were joined by means of a glass hair, when pleochroic crystals of (C₆H₅NH)AuBr₄ were formed within 30 sec.; limit, 0.0001 molar or 0.02 μ g. Au. For S the reagent was bromocresol green soln., alk. phase. A Pyrex tube 10 cm. long and 3 mm. bore was made with an S bend at the lower end and another S bend enlarged near the top. A fragment of sulfide or sulfite was placed in the lower bend and the reagent in the upper bend. The mineral was heated to the softening point of Pyrex (about 700°) and any S present passed up the tube as SO₂ and changed the color of the reagent, previously made blue by a trace of NaOH, to yellow; limit 0.2 μ g. S. An equally sensitive test for S using the same app. depends on a decoloration of a starch-iodine soln. L. W. RIGGS

A sulfoarsenite of lead near jordanite from the Andreevsk mine in the southern Urals. S. S. SMIRNOV. *Mém. soc. russe. min.* [2], 54, 21-5(1925); *Mineralog. Abstracts* 3, 448.—An analysis of jordanite gave: S 17.80, As 9.46, Sb 2.10, Pb 69.85, insol. 0.57, sum 99.78%; sp. gr. 6.38; formula 4 PbS.(As,Sb)₂S₃. J. F. SCHAIER

The hydrothermal paragenesis of quartz and arsenic minerals in the altered quartz porphyry of Saubach and some properties of pharmacosiderite and symplectite. F. HEIDE. *Z. Krist.* 67, 33-90(1928).—There is a definite relation between temp. of formation and type of twinning in quartz. Dauphiné and brazilian twins form up to 575°, but Japanese twins only at lower temps.; the latter are never found in pegmatites but occur on milky, smoky or rock crystal, never amethyst quartz. The quartz in these beds formed below 575°, and the As minerals under 200°. *Pharmacosiderite*, 2FeAsO₄.Fe(OH)₃.5H₂O, loses 5 mols. of zeolitic H₂O up to 233 ± 1°, where decompn. begins. The remarkable color change it shows when treated with acids or bases is due to incipient decompn., caused by the infiltration of the soln. in the large meshes of the lattice. *Symplectite*, Fe₃(AsO₄)₂.8H₂O, becomes blue-black because of oxidation of Fe⁺⁺ to Fe⁺⁺⁺; this can be produced artificially by H₂O₂. The mineral is decompd. by KOH, forming Fe(OH)₃. *Scorodite*, FeAsO₄.2H₂O, reacts toward KOH and HCl like symplectite. An extensive bibliography is included. L. S. R.

Structure of rutile. LASZLO TOKODY. *Mathematik Természettudományi Értesítő* 44, 247-53 (Hungarian), 254 (German summary) (1927); *Mineralog. Abstracts* 3, 429.—By the Debye-Scherrer x-ray method, rutile gave for the dimensions of the tetragonal cell $a = 4.4923$, $c = 2.8930$ A. U., contg. 2 mols.; calc. $d = 4.511$. The shortest distance between Ti and O atoms is 2.11 A. U. J. F. SCHAIER

Nomenclature of bauxite. FRITZ KERNER. *Montan. Rundschau* 20, 257-9 (1928).—The bauxite minerals may be divided into the following groups according to mineralogical and chem. compn.: only Al₂O₃.H₂O, diasporite; more Al₂O₃.H₂O than Al₂O₃.3H₂O, "unterbauxite" or "miobauxite;" equal amts. of Al₂O₃.H₂O and Al₂O₃.3H₂O, bauxite; more Al₂O₃.3H₂O than Al₂O₃.H₂O, "uber-bauxite" or "pliobauxite;" only Al₂O₃.3H₂O, gibbsite. Aluminous laterite and siliceous bauxite are synonymous. J. F. SCHAIER

Two scapolites from the river Slyudyanka region, Baikal. S. S. SMIRNOV. *Mém. soc. russe. min.* [2], 55, 354-61(1926); *Mineralog. Abstracts* 3, 448.—Analyses of "stroganorite" and "glaucolite" are given. J. F. SCHAIER

Association of gold and tetradymite in S. Rhodesia. B. LIGHTFOOT. *Trans. Geol. Soc. S. Africa* 30, 1-4(1927).—An analysis of the tetradymite occurring with Au at the New Mystery Mine, Ratanyana farm, West Givanda District gave: Bi 56.09, Te 33.40, Se trace, S 4.69, SiO₂ and insol. silicates 5.90, sum 100.08%. No Au telluride were found. J. F. SCHAIER

Mineral resources of the United States in 1927. FRANK J. KATZ AND MARTHA B. CLARK. *Bur. Mines, Mineral Resources of U. S. 1927*, preliminary summary, 120 pp. (published Aug. 13, 1928). E. H.

Tyuyamunite and some minerals of the uranite group. E. Y. RODE. *Mém. soc. russe. min.* [2], 54, 377-83(1925); *Mineralog. Abstracts* 3, 447.—After treating with acetic acid to remove calcite and drying over H₂SO₄ at room temp. an analysis of tyuyamunite gave: UO₃ 56.07, V₂O₅ 18.92, CaO 5.08, BaO 0.32, MgO 0.12, Fe₂O₃ 0.86, insol. 0.31, H₂O 17.53, sum 99.21%. The zeolitic nature of the H₂O in members of the uranite group is discussed. J. F. SCHAIER

Research in processes of ore deposition. WALDEMAR LINDGREN. *Am. Inst. Mining Met. Eng. Tech. Pub. No. 78*, 14 pp.(1928).—A general survey of geochem. research, outline of problems and suggestions for the future. J. F. SCHAIER

State and density of solutions depositing metalliferous veins. WM. H. EDMONS.

Am. Inst. Mining Met. Eng., Tech. Pub. No. 71, 13 pp.(1928).—There is little or no evidence to support the theory that metalliferous veins were deposited from ore magmas. At Lead, S. D., very dil. solns. are depositing vein material around fragments of schist. The general question of rock inclusions in veins is discussed at length. J. F. S.

Magmatic origin of ores. R. H. RASTALL. *Geol. Mag.* 65, 270-9(1928).—A definition of "magmatic" and general discussion of current and historical theories of ore genesis. J. F. SCHAIRER

Ore magmas (I) (II). J. H. L. VOGT. *Eng. Mining J.* 123, 645-50, 682-4(1927).—The term magma is defined as "liquid high-temp solns" often carrying dissolved volatile compds. in great quantity. Ore magmas are divided into classes: those due to 1, the formation of 2 liquid phases; 2, the concn. of first crystg. minerals; 3, the concn. within the residual magma. Normal contact metamorphism is a purely thermal process due to the reactions in the solid phase, and may be explained without involving hot gases from the magma. J. F. SCHAIRER

Status of leached outcrops investigation. ROLAND BLANCHARD AND P. F. BOSWELL. *Eng. Mining J.* 125, 280-5, 373-7(1928).—In studies of secondary enrichment of ore deposits criteria have been established to recognize limonite derived from the various Cu, Zn and Pb sulfides. Sufficient S must be present for sulfides to dissolve by oxidation. Even though oxidation of a sulfide occurs no limonite will form unless Fe salts are present in soln. Where Fe salts are present in a soln. of high acidity, and no neutralizer is encountered, Fe may be carried for long distances before pptn. as limonite. J. F. SCHAIRER

Tertiary mineralization of the northern Black Hills. J. P. CONNOLLY. S. Dakota School Mines, Dept. Geol. Min., *Bull. No. 15, 130 pp.*(1927).—Mainly geological. The age of the pegmatites obtained from radioactive data is not in agreement with geological observations. A bibliography of the economic geology of the northern Black Hills is included. An analysis of calcite from ore gang and assays and analyses of Homestake mine ore concentrates are given. J. F. SCHAIRER

Mineral constituents of the Broken Hill lode. F. L. STILLWELL. *Proc. Australasian Inst. Mining Met.* 1927, 97-172.—A complete mineralographic study of the Broken Hill ores was made and the microscopic data were given. *Analyses of arsenopyrite, meneghinite, mangan-hedenbergite and manganiferous calcite* are included. An unnamed and "probably new Ni-Co-Sb mineral" is incompletely described. It occurs as small inclusions in arsenopyrite. It is possibly orthorhombic, similar in color and hardness to arsenopyrite, and affects polarized light strongly. On etching with HNO₃ it effervesces more briskly than arsenopyrite and is slowly tarnished brown by FeCl₃. Microchem. tests on excavated particles indicate the presence of Co, Ni and Sb. It may be only antimoniferous safflorite. J. F. SCHAIRER

Principal base metal and base mineral resources of the Union of South Africa. C. J. N. JOURDAN. *J. Chem. Met. Mining Soc. S. Africa* 28, 1-13(1927); cf. C. A. 20, 3411.—Records of the total production of metallic and non-metallic minerals of S. Africa are given, with analyses of coals, Fe, Cu and Mn ores, asbestos, corundum, magnesite and talc, and a discussion of previous mining operations. J. F. S.

Occurrence of galena in clay, southern Shan States, Burma. W. H. RUNDALL. *Bull. Inst. Mining Met.* No. 276, 1-10(1927); No. 281, 37-42(1928).—Beds of argenterous galena occur in Shan carrying 10 to 70 oz. Ag to 1 ton of Pb. Analyses of Pb slag, limestone and gang are included. J. F. SCHAIRER

Sedimentary metalliferous deposits of the red beds. JOHN W. FINCH. *Am. Inst. Mining Met. Eng. Tech. Pub. No. 51, 7 pp.*(1928).—The original source of the Cu ores of the red beds was weathered rocks. The ores were concd. by stream action and after burial were altered from carbonates to sulfides. In early Tertiary time these sulfides were concd. by chem. action and secondary enrichment processes. The small size of the deposits and their nonuniform character render them commercially unprofitable. J. F. SCHAIRER

Mineral production of India during 1926. E. H. PASCOE. *Records Geol. Survey India* 60, 205-91(1927); cf. C. A. 21, 1239.—Decreases in production over 1925 are reported for chromite, Au, jadeite, magnesite, mica, oil, saltpetr, apatite, bauxite, gypsum, ocher, serpentine, soda. Increases are reported for coal, Cu, Fe, Pb, Ag, Mn, Sn, W, Zn, FeSO₄, Sb, amber, alum, diamonds, monazite, ilmenite, clays, fuller's earth and barite. J. F. SCHAIRER

Useful fossils, natural raw materials of the Kuban territory and Black Sea district. P. N. CHIRVINSKI. *Arbeiten Nord-Kaukasischen Assoc. wiss. Inst. Rostov am Don* No. 24, 232 pp.(1927)(Russian); *Mineralog. Abstracts* 3, 443.—Materials in Kuban territory include oil, gas, coal, graphite, peat, S, Pb-Zn-Ag ores, ores of Cu, As, Hg, Fe, Mn,

Cr, Ni, saltpeter, Na_2SO_4 , MgSO_4 , FeSO_4 , alum, gypsum, barite, celestite, salt, borates, Br and I salts, building and ornamental stones, refractories, lithographic stone, clays, sand and gravel, feldspar, granite, asbestos, serpentine, talc, petalite, precious stones. From the Black Sea are described fuels, pyrite, ores of Cu, Ag, Pb, Zn, Fe, building materials, cement shales, calcite, Iceland spar. A complete index of subjects and localities is added. J. F. SCHAIRER

A newly discovered manganese deposit in the northern Caucasus. A. KOLOD-JAZNY. *Bergjournal* 1925, No. 5; *Z. prakt. Geol.* 33, 167; *Chem. Zentr.* 1927, I, 1812.—The ore lies in 2 beds in Oligocene strata. Its Mn content is 30–60% and about 3,000–000 tons of ore are present. C. C. DAVIS

Fluorspar, lead and zinc deposits of Western Transvaal. W. KUPFFERBURGER. *Trans. Geol. Soc. S. Africa* 30, 5–56 (1927).—Descriptive. Analyses of dolomite rock, talc-calcite rock, talcy-dolomite and Mn-earths are included. J. F. SCHAIRER

Genesis of Grecian magnesite. J. R. THOENEN. *Am. Inst. Mining Met. Eng. Tech. Pub.* No. 67, 9 pp. (1928).—Alteration of serpentine by H_2O does not completely explain the occurrence of magnesite. T. suggests that the carbonate ore may be of magmatic origin. J. F. SCHAIRER

Corundum. C. J. N. JOURDAN. *J. Chem. Met. Mining Soc. S. Africa* 28, 230–6 (1928).—In the north of the Union of S. Africa the corundum fields have an area of 2000 sq. miles. A typical analysis of S. African corundum is: Al_2O_3 94.51, SiO_2 1.54, Fe_2O_3 1.23, TiO_2 0.02, combined H_2O 2.70%. Analyses of bauxites from France and the U. S. A. are given. The av. corundum content of the Transvaal reef ore is "probably somewhere near 40%." A plea is made for developing the deposits in S. Africa. E. G. R. ARDAGH

Mineralogical data on the bauvites of Pays de Fenouillet. JACQUES DELAPPARENT. *Compt. rend.* 186, 1560–1 (1928).—Lithological. L. W. RIGGS

Geology of Bundi State, Rajputana. A. I. COULSON. *Records Geol. Survey India* 60, 164–204 (1927).—The lower Bhandar limestone is an important raw material for lime and cement. Analyses of limestones used for lime and cement and complete data on the compn., setting time, tensile and compression strength of the cements are given. J. F. SCHAIRER

Kaolin and associated clays of Punk Island. L. H. COLE AND J. F. MCMAHON. *Investigations in Ceramics and Road Materials, Dept. of Mines, Can., No. 690*, 25 36 (1928).—This is a detailed report on the location and description of clay deposits of Punk Island in Lake Winnipeg. The topography of the island is given and means of transportation to the deposits. Tests were made of the clays and their economic importance was indicated. L. B. MILLER

Report of the director for 1926. H. B. MAUFE. *S. Rhodesia Geol. Survey* 1927, 11 pp.; *Mineralog. Abstracts* 3, 445.—The sequence of events in serpentinization has been worked out and it is observed that the nearer the fiber approaches the formula $3\text{MgO} \cdot 2\text{SiO}_2 \cdot 2\text{H}_2\text{O}$, the better it is commercially. J. F. SCHAIRER

Talc deposits near Kaaomuiden, in Eastern Transvaal. A. I. HALL. *Trans. Geol. Soc. S. Africa* 30, 69–88 (1927).—Three varieties of talc occur: green foliated talc of high quality, green massive talc and steatite. Analyses of talcs and dolomite are given. The origin of the talc beds is due to chem. reactions characteristic of the zone of weathering, i. e., hydration and carbonation. J. F. SCHAIRER

The origin of petroleum. J. A. LEBEL. *Bull. soc. chim.* 43, 654–7 (1928).—Three theories for the formation of petroleum are reviewed: (1) fermentation of org. material, (2) decompn. of coal under the influence of heat and pressure, (3) the reaction of water on the metals. The last theory is believed to account for the petroleum in the Baku or Mesopotamian fields, since no anthracite is found in this region and metals are found in the asphalts. A sample of granite was tested and believed to allow a penetration of water of 0.01 mm. per day, which would account for the presence of water. D. H. P.

Economic geology of the Castlegate, Wellington and Sunnyside quadrangles, Carbon County, Utah. FRANK R. CLARK. *U. S. Geol. Survey, Bull.* 793, 162 pp. (1928).—The Wellington and Sunnyside quadrangles are estd. to contain over 2 billion tons of bituminous coal of which 60% is recoverable. Analysis of about 50 samples of coal from this area gave only 6 samples, as from the mine, with B.t.u. below 12,000. The recoverable coal in the Castlegate quadrangle is estd. at 720 million tons. L. W. RIGGS

Constituents of igneous rocks. SUMINOSUKE ONO. *Proc. Phys. Math. Soc. (Japan)* 9, 109–13 (1927).—A simple relation between the amts. of constituents of igneous rocks is that the sum of the amts. of O, Ca, K and Ti is a const. a little above 53% while that of the other elements is 47%. The ratio of these figures may be given as

mass nos. of O and N. O. calls these the O and N series. This relation is correlated with Eddington's assumption of an extremely ionized state in hot stars. J. F. S.

Plutonic intrusions of the southern uplands east of the Nith Valley. FREDERICK WALKER. *Geol. Mag.* 65, 153-62(1928).—Analyses of porphyritic hornblende-biotite granodiorite, augite-biotite quartz-diorite, hornblende-biotite granodiorite and quartz-augite-hypersthene porphyrite are given. J. F. SCHAIRER

The tholeiites and dolerites of the Dalmahoy syncline. ROBERT CAMPBELL AND J. W. LUNN. *Trans. Roy. Soc. Edinburgh* 55, 489-505(1927).—Analyses of tholeiite, segregation veins and dolerite are given. J. F. SCHAIRER

Presence of alkaline lavas in the Northern Aegean Sea. CONST. A. KTÉNAS. *Compt. rend.* 186, 1631-3(1928).—This region furnishes calco-alk. lavas assocd. with magmatic alk. deposits. Four chem. analyses of the rocks by Raoult are reported and the results are discussed from the lithologic point of view. L. W. RIGGS

A new region of nephelinic intrusive rocks in Madagascar. A. LACROIX. *Compt. rend.* 186, 1457-60(1928).—The nephelinic syenite in question was found midway between Manatorwotra and Ankarimbolo in the province of Farafangana. Analyses by Raoult of 3 specimens are reported, and the lithological relations of the rocks are discussed. L. W. RIGGS

Igneous and metamorphic history of Cromar, Deeside, Aberdeenshire. H. H. READ. *Trans. Roy. Soc. Edinburgh* 55, 317-53(1927).—Equations showing chem. changes in contact metamorphism for the alteration of sillimanite, andalusite, staurolite and anorthite are given. Analyses of augen-gneiss, oligoclase-biotite gneiss, plagioclase-porphyroblast schist and granite are included. J. F. SCHAIRER

Chlorite schist from West Tatra. STANISLAW JASKOLSKI. *Bull. intern. acad. polonaise* 1927, 703-17.—Analyses of chlorite schists and chlorites are included. J. F. SCHAIRER

A metamorphosed nodular shale previously described as a "spotted" metamorphic rock. L. R. WAGER. *Geol. Mag.* 65, 88-91(1928).—The mineralogical compn. of nodules in a shale is calcd. from an analysis. J. F. SCHAIRER

Sketch of the geological features and of the mining at Jáchymov. JAN AUER. *Hornický věstník* 28, 532-6, 541-5(1927); *Mineralog. Abstracts* 3, 443.—New analyses of red dolomite are given. J. F. SCHAIRER

Dust fall in the central part of Poland on April 26 to 28, 1928. HENRYK ARCOWSKI AND EDWARD STENZ. *Compt. rend.* 186, 1858-60(1928).—Chem. analysis of the dust gave: SiO₂ 57.94, Al₂O₃ 12.30, Fe₂O₃ 5.49, MgO 1.77, CaO 2.03, Na₂O 0.31, K₂O 2.97, P₂O₅ 0.24, MnO 0.06, SO₃ 0.13, CO₂ 0.65, Cl trace, org. C 2.94, H₂O (105.3°) 5.15, H₂O (hygroscopic) 7.01, sum 99.69%. The H₂O and org. substances being deducted the compn. was silicates and quartz 76.46, colloidal substances (clay) 20.36, carbonates 2.38, sulfates 0.24, phosphates 0.56. From the chem. compn., microscopic appearance and the weather conditions which indicated a hurricane in the region north of the Black Sea on April 25, it was concluded that the dust came from south central Russia. L. W. RIGGS

Geological notes on the island of Dominica, B. W. I., KENNETH W. EARLE. *Geol. Mag.* 65, 169-87(1928).—Soil was extd. with 20% HCl and the soln. analyzed; data for 3 soils are given. J. F. SCHAIRER

Origin of the mineral springs of Tarasp-Schuls. AD. HARTMANN. *Vierteljahrsschr. naturforsch. Ges. Zurich* 72, 237-90(1927).—The origin of the acid springs lies not in pyrite weathering but in the reaction of volcanic gases with water and rocks. CO₂ is the principal dissolved gas. Seventeen water analyses and 7 gas analyses are included. Data are given on the rate of flow, temp., mineral and CO₂ content of 12 springs; 5 analyses of the country rock and efflorescences near the springs are given; B₂O₃, Cl and NH₃ were detd. with great care in many of the springs. All the analyses and data point toward a volcanic origin of the constituents of the springs. J. F. SCHAIRER

Joly's radioactivity hypothesis for the explanation of mountain formation. FRANZ LÖTZE. *Nachr. Ges. Wiss. Göttingen Math.-physik Klasse* 1927, 75-111.—A discussion of the relation of the earth's thermal history and radioactivity to the facts of geology with an extensive bibliography. Conclusion: the Joly radioactive theory as modified and interpreted is not in harmony with the facts of geology. A harmonic analysis of the data is given. J. F. SCHAIRER

The arc spectrum of uraninite from Kasolo (VERHAEGHE) 3. The crystal structure of bixbyite and artificial Mn₂O₃ (ZACHARIASEN) 2. Determination of combined water in natural sulfates (ŠEBELIK) 7.

C. J. DEMOREST, R. H. ABORN

Utilization of by-products of the great siderurgical industry. GIUSEPPE TOMARCHIO. Reale Scuola Industriale Paolo Boselli, Savona. *Met. italiana* 20, 259-68(1928).—A review and discussion, dealing with distn. products of coal, blast-furnace gas and slag and cements. C. C. DAVIS

Copper milling research in Michigan. A. W. FAHRENWALD. Bur. Mines, *Repts. of Investigations* No. 2878, 5 pp.(1928).—In Michigan, Cu occurs almost entirely native (amygdaloid and conglomerate), a slight amt. of CuS being present. Since the conglomerate ore is efficiently treated, the amygdaloid, alone, is considered. Four to 7 lb. Cu per ton is lost in the tailings in the present-day practice. Microscopic examn. of the table tails showed that much flakey and fine metallic Cu was escaping, suggesting the use of flotation, which previously has been unsuccessful. In the present researches table concentrate contg. 28-mesh and 35-mesh Cu floated well and 65-mesh floated readily when xanthate was used in the pulp, which is made alk. with Na_2CO_3 , CaO or NaH_2PO_4 in small amts., in conjunction with Barrett No. 4 and No. 5 steam-distd. pine oils. Flotation is found to be easier when finely ground barren rock is mixed with the pulp. With table feeds of various operating mills this method of flotation repeatedly gave tailings which carried as little as 0.06% Cu. The advantages of this method of flotation over the all-gravity process are claimed to be: (1) the additional recovery of Cu (3,240,000 lb. per year); (2) lower smelting cost of concentrate; (3) lower slag loss; (4) no table middling regrind. This method of flotation of amygdaloid Cu ores is to be tested in Michigan mills. J. BALOZIAN

Flotation equipment of the Combined Metals Reduction Company. H. D. KEISER. *Eng. Mining J.* 126, 253-5(1928). E. H.

The evolution of slime treatment on the Witwatersrand and gold mines. J. R. THURLOW AND T. K. PRENTICE. *J. Chem. Met. Mining Soc. S. Africa* 28, 251-70(1928).—A brief description and comparison of respective systems of filtration employed in this district are given. Special reference is made to continuous filters. For practical metallurgical purposes all pulverized ores may be divided into two fractions: one sand, which is leachable, and the other slime, which is unleachable without the application of external pressure. Witwatersrand slime consists essentially of silica and clay. The leachable portion of the ore is sepd. by direct filling or by intermediate filling. Each of the following subjects in connection with the development of slime treatment is discussed sep.: (1) production of slime; (2) collection and thickening of slime; (3) soln. of the Au in slime; (4) sepn. of Au-bearing soln. from the treated slime; (5) pptn. of the Au from the cyanide solns; and (6) extns and costs. All the latest plants on the Rand have installed the Zn-dust process, which has the following advantages over filiform Zn pptn.: (1) a complete clean-up at month end, with elimination of the carry-over of a high % of monthly output; (2) reduced Zn consumption; (3) lower handling loss; (4) greater security against theft; (5) reduced labor cost; and (6) saving in smelting operation. Several charts, flow sheets and a brief discussion are included. W. H. BOYNTON

Carbon deposition near furnace top. F. C. HOWARD. *Iron Age* 122, 271(1928).—Calcs. based on the work of Kinney (*C. A.* 21, 1428, 2863) strongly indicate that the deposition of C in the top of the blast furnace comes from the blast-furnace gases themselves and not from the volatile matter in the coke charge. DOWNS SCHAAF

The operation of quicksilver retorts. HOMAR L. JOHNSON. *Eng. Mining J.* 126, 215-7(1928).—Recent high prices for Hg have resulted in renewed activity in several old producing mines. Two types of retorts are used: "D" retorts resembling the letter with the straight side lying horizontally and consisting of heavy cast iron; and Johnson-McKay tubes or pipe retorts of cast-iron pipes 12 in. or more in diam. and of varying

lengths. The "D" type is more substantial and offers less hazard of mercurial poisoning to the operator. Its initial costs are higher, it is easier to operate, but requires more fuel than the pipe retort per unit of ore treated. Two charges per 24 hrs. is rather common practice. Ores contg. S are mixed with hydrated or slaked lime to prevent pptn. of HgS in the condensers. On a "D" retort charge of 750 lb. (340 kg.) an av. figure for green scrub or jack pine is about 1 cord per retort day. The details of operation are described and several illustrations are included. Ways in which local conditions necessitate variations in practice are pointed out.

W. H. BOYNTON

The estimation of the material and heat balance of blast furnaces from throat gas analysis and the blast quantity. HUGO BANSEN. *Archiv Eisenhüttenwesen* 1, 245-61 (1927).—Formulas and tables are given for detg the analysis of combustion gases from those of the mixed throat gases, and from the values obtained the material and heat balance of the furnace is calcd. For calcg. the heat balance the principal assumption made for the thermal equil. is: $\text{coke} \times \text{metallurgically available heat} = \text{pig Fe} \times \text{metallurgically required heat}$. The heat available from a kg. of coke is calcd. from throat gas analyses, and throat gas and blast temps. That required for a ton of crude Fe is detd. from the crude Fe compn., that of the scrap Fe charged and the amt. of slag for a ton of pig Fe, and from this the coke consumed calcd. From the examples given, the influence on the consumption of coke of the gas compn., the gas and blast temps., and the quantity of slag is shown; in a sec., the effect of operating fluctuations on the material and thermal balance is discussed. These investigations show that blast furnaces should be operated under careful and continual supervision. An instrument board is developed which gives continuously the compn. and temp. of the waste gases.

J. BALOZIAN

The heat balance of the Siemens Martin furnace with special regard to waste-gas losses. CARL SCHWARZ. *Archiv Eisenhüttenwesen* 1, 273-83 (1927).—The heat balances of other investigators for the Siemens-Martin furnace are critically reviewed, the useful heat, and the heat losses in the hearth zone and in the lower part of the furnace being dealt with in detail. In expts. to show the influence of the distribution of flame, the relations between preheating, the temp. of the flame with and without disson., and the quantity of heat available on cooling the combustion gases are obtained. From these it is apparent, that with increasing temps. of preheating there is an increase both in the heat available over 1700°, and that tied up through disson. Conclusion: Even if one suitably suppresses the losses between the hearth and stack there will still remain sufficient waste-heat at a high enough temp. for utilization in the waste-heat boiler, even after as much heat as possible has been consumed in preheating. A thermal balance diagram is given which combines the advantageous points of the heat content-temp. diagram of S. (*Stahl u. Eisen* 45, 795 (1925)), and the heat-flow diagram for Bansen (*Ber. Stahlw. Aussch. V. d. Eisenh.* 92, 7 (1925)), replacing formulas for the comprehension of the relations of the balance.

J. BALOZIAN

The high-frequency induction furnace applied to metallurgy. FRANZ WEVER and GUSTAV HINDRICH. *Archiv Eisenhüttenwesen* 1, 345-55 (1927); cf. *C. A.* 22, 1282.—A continuation of the work performed at the *Kaiser Wilhelm Inst. Iron Research* in 1926 (*C. A.* 21, 2848) on the metallurgical behavior of the high-frequency induction furnace. When an acid hearth is used, the C contents of the steels are not markedly influenced by Mn in excess of 0.06-0.8% (excepting at very high concns.), cannot be lowered below 0.05% even by the addn. of a large excess of Fe_3O_4 and can only be quantitatively removed by an excess of dissolved Fe_2O_3 . By exactly measuring the charge and reaction time, the melt may be quantitatively deoxidized without the use of an excess of the deoxidizing material. Unalloyed soft steels and C-poor Cr steels when refined in the induction furnace are not equal in their C content to the basic C steels prep'd. earlier, and because of their small Mn and Si are free of red-shortness, all hot-working processes increasing. The multihardness nos. of acid-melted C steels and those from the acid Siemens-Martin furnace are reached at the same compns. The alloy and the trade crucible steels have the same qualities. Steels refined in a 100 kw. high-frequency induction furnace show multi-hardness nos. which are greater than those of trade steels normally, in spite of unfavorable conditions. The high reaction energy of the high-frequency furnace on account of the active bath motion also takes place in the larger furnaces as is shown by the low S content (0.008%).

J. BALOZIAN

The economical estimation of charges, sort of crude iron and the operating conditions in blast-furnace management. G. BULLE. *Archiv Eisenhüttenwesen* 1, 161-76 (1927).—The influence of various qualities of ores and coke, kinds of crude Fe and varying operating conditions in blast-furnace management on the heat needed, and the

probable price of ore and coke are calcd. from thermal and metallurgical considerations. The thermal calcs. are based on those of Osann (*Lehrbuch der Eisenhüttenkunde* Vol. 1 (1923), C. A. 18, 1107), but allow for losses in waste gas, and for cooling and radiation losses. It is proposed to obtain exactly the ore required for a run from a numerical tabulation of the thermal and metallurgical values of various charges, types of crude Fe and working conditions. J. BALOZIAN

The calculation of the carbon consumed or the oxygen gasified by direct reduction in the blast furnace. ED. MAURER. *Archiv Eisenhüttenwesen* 1, 331-7 (1927). J. B.

The use of silica gel as a medium for drying blast. EDWIN H. LEWIS. *Iron Coal Trades Rev.* 65, 444-6 (1927); cf. C. A. 21, 3868.—Silica gel is being used at the Wishaw works of the Glasgow Iron and Steel Co., Ltd., for the drying of the blast with considerable success. The moisture content is cut down from 3.5 (1925) to around 1.1 to 1.6 grains per cu. ft. This results in a 12 to 17% increase in output and a 4/6 to 5.7% saving in fuel. LESLIE B. BRAGG

Diffusion of zinc into copper. SAMUEL L. HOYT. General Electric Co. *Am. Inst. Mining and Met. Eng. Tech. Publication* No. 128, 4 pp. (1928).—The rate of diffusion of a Zn coating into Cu strips was detd. at 9 temps. by measuring its amt. for 3 time intervals, the expense of the investigation being reduced to the min. Plotting the time against the log of the penetration gave a straight curve at each temp. The strips 5 to 6 mils thick would be converted entirely into brass in 4 5 hrs. at 550°, or in 30 min. at 650°. The effect of temp. on the time required for a given penetration is plotted as a similar straight curve. The rate of penetration increased with time, indicating the existence of an "incubation" period. GEO. F. COMSTOCK

Speiss and the metals of the platinum group. H. RUSDEN and J. HENDERSON. *J. Chem. Met. Mining Soc. S. Africa* 28, 270-2 (1928); cf. C. A. 22, 2130.—Discussion by G. H. Stanley. There is a question whether osmiridium, etc., are combined in speiss as arsenide, dissolved, or in mech. suspension. Osmiridium alloys appear to be "wetted" by Pb with increasing ease as the temp. rises. Pt behaves similarly with Hg. Removal of As from speiss by roasting, S. considers, is preferable to the use of such large quantities of litharge in smelting, producing thereby such enormous amounts of Pb for subsequent treatment. The surprisingly low results obtained on smelting with Pb on the larger scale were due to the insol. of osmiridium in Pb. An elec. furnace might be preferable to a pan furnace, though the induction type would not be practical, because of the poor cond. of the charge. W. H. BOYNTON

Has aluminum a transformation point? ALFRED SCHULZE. *Z. Physik* 49, 146-54 (1928).—The results of a no. of previous investigations are summarized. Some of these indicate a transformation point above 500° while others give no indication of any such change. To settle the question the elec. resistance of 3 specimens of Al of varying degrees of purity was measured at intervals from 300° to 615°. The first sample was 99.6% Al with 0.18% Fe, 0.22% Si and 0.01% C as impurities; the second was 99.9% pure Al with 0.04% Fe; the third was 99.94% pure Al. The temp.-resistance curves for the first 2 show slight breaks in the neighborhood of 425° and again near 550°. These are verified by plotting variation of resistance against temp. However, both the resistance-temp. and the variation-of-resistance-temp. curves for the 99.94% sample are perfectly regular and neither shows any indication of a transformation point. It is therefore concluded that the breaks in the curves for the other samples are to be attributed to impurities, and that there is no transformation point in pure Al up to 610°. Results obtained for the coeff. of thermal expansion of 2 samples indicate that this quantity is not a suitable magnitude to use in investigations of this sort. W. W. STIFLER

The myth of the lost art of hardened copper. F. L. THURMOND. *Mining J. (U. S.)* 11, 15 (1928).—Present-day metallurgy shows the fallacy of the hardened Cu myth. E. M. SYMMES

Absorbability of gases in casting copper and effect of adding cuprosilicon. O. W. ELLIS. Westinghouse Elec. & Mfg. Co. *Am. Inst. Mining Met. Eng. Tech. Publication* No. 123, 26 pp. (1928).—Previous work on the soly. of gases in Cu is reviewed. Water vapor had a high soly. in Cu and caused oxide formation. Expts. are described in detail in which about 250 lb. of Cu were melted under different conditions of access of air and contact with charcoal and Si-Cu and poured into chill or sand molds. Excellent photomicrographs of Cu₂O in Cu are shown. Si reduced Cu₂O in accordance with the theoretical equation and, when all Cu₂O was eliminated, excess Si removed the gaseous O. The action of Si in promoting soundness was not entirely explained. Cu melted in a reducing atm. in an elec. furnace was nearly free from Cu₂O as well as CO and H₂ and contained chiefly CO₂, N₂ and H₂O. Oxidized Cu in contact with char-

coal absorbed C in the form of CO and CO₂ up to a limit of 21.9% by wt. of gas. Cu also absorbed C from a graphite mold. The presence of gaseous O was necessary for satn. of Cu with C. At higher temp., the ratio of occluded CO₂ to CO increased but the CO₂ cannot be more than 80.5% by wt. of the total occluded gas. The total gas occluded was greatest in aerated Cu and least in Cu free from oxide. H₂ was found in very small quantities, except when oil was used for melting, when Cu₂O may have been reduced by CH₄ with formation of H₂ in the metal. Expts. on the gases obtained by subjecting molten Cu to a vacuum showed that they were practically the same, except for more N₂, as those obtained in the same way from the solid castings, from which the results noted were derived. The vol. of gas occluded by solid Cu depends on the melting and cooling conditions. In oil furnaces, Cu₂O but not ZnO may be eliminated by a reducing atm. CO₂, CO and H₂O are the chief gases occluded when melting Cu with oil.

GEO. F. COMSTOCK

Effect of cold rolling and heat treatment on physical properties of Britannia metal. B. EGEBERG AND HENRY B. SMITH. International Silver Co., Meriden, Conn. *Am. Inst. Mining and Met. Eng. Tech. Publication No. 124*, 7 pp. (1928).—Sn contg. 7% Sb and 2% Cu (Britannia Metal) can be cold-rolled and highly polished, and resists corrosion. Samples cold-rolled in stages down to 0.032 in. thick, and heated to various temps. up to 440° F., were tested for hardness by the scleroscope and Brinell methods. The former method showed increased hardness as the thickness decreased by cold rolling, but the Brinell method showed a decrease in hardness, which is considered correct. Reheating the cold-rolled samples gave a progressive rise in Brinell hardness, on account of recrystn. The speed of cooling had little effect on the results. The Brinell hardness as cold-rolled to $\frac{1}{16}$ in. thickness was 13.3, and on reheating to 400° F. it was 18.6. The Brinell hardness was 23.8 as cast. Cold rolling to $\frac{1}{16}$ in. from $\frac{1}{8}$ in. thickness did not soften a sample appreciably, but from $\frac{3}{16}$ in. the softening was apparent. A shell spun from an annealed blank was twice as strong in compression as one spun from a blank not annealed. A thinner ingot will give a stronger sheet of a given size in this metal. The smaller the reduction in rolling, the higher is the annealing temp. required for stiffening.

GEO. F. COMSTOCK

Effect of cadmium on mechanical properties of brass. WALTER BANNAU. *Am. Metal Market* (Mag. Sect.), 35, 12-4 (1928).—A series of tests on 70 and 60% Cu-Zn alloys contg. from 0 to 4.5% Cd show that up to 0.5% Cd the structure is like brass contg. no Cd. With more than 1% Cd, free Cd is found in the alloy. The first effect of Cd is seen in lessened resistance to shock. With a higher % the elongation suffers and speedily becomes very low. The free Cd is isolated in filaments that have a tendency to surround the crystals of alloy. In brasses contg. 55% Cu even 3.6% Cd does not diminish the tensile strength markedly, but 1.8% Cd greatly affects the ductility and brittleness.

E. G. R. ARDAGH

Crystals of β -brass. V. GÖLER AND G. SACHS. *Naturwissenschaften* 16, 412-6 (1928).—Cu-Zn alloys with 50 to 54% Cu by weight (β -brass mixed crystals) show an unexplained transformation between 300° and 470°. By Laue photographs of β -brass between 400° and 500° no lattice changes could be found. The temp. influence (disappearance of weak interference spots, and weakening of sharp spots) appears at rather low temp. (300°), possibly indicating an increased heat motion effect which also is apparent from the case of recrystn. of brass at low temp. On a mono-crystal rod slip lines appeared after 4.4% elongation following a rhombododekahedral plane. Fracture planes were often found to have the same orientation. A short description is given of the novel goniometer furnace for Laue photography at elevated temps. (cc. tube furnace).

B. J. C. VAN DER HOEVEN

Effect of compression and tension on brass crystals. G. SACHS AND H. SHOJI. *Z. Physik* 45, 776-96 (1927).—The mech. deformation of single crystals of brass in the form of rods has been examd. for compressions and for tensions up to 200 kg. per sq. mm. For forces of the order of 4 kg. per sq. mm. such crystals exhibit mech. hysteresis.

B. C. A.

Cast iron resistant to acids and alkalis. H. G. HAASE. *Stahl u. Eisen* 47, 2112-7 (1927).—The most satisfactory resistance to attack by mineral acids is shown by cast iron of the following compn.: 3.3-3.5% C, 1.3-1.4% Si, about 0.75% Mn, 0.3-0.5% Ni, not more than 0.2-0.3% P, and not more than 0.07% S. Increase of S is particularly deleterious, more Mn increases the rate of corrosion relatively slightly, with Si max. occur in the corrosion curve at 2.5 and 7% Si, and with P and Ni little difference is noticeable in the rate of corrosion with double the above amts. The cast iron most resistant to alkali contains 3.3-3.5% C, 1.2-1.4% Si, 0.3-0.4% Mn, not more than 0.3% P, not more than 0.08% S and 0.3-0.5% Ni. Increase of P reduces the

resistance to attack by alkali hydroxides, as also does increase of Si to a max. of 7% Si. Metal with the casting skin intact is more resistant than metal from which this skin has been removed.

B. C. A.

Heat treatment of gray iron. EDWARD E. MARBAKER. *Iron Age* 122, 282-5 (1928).—Preceding investigations contained in 21 papers concerning the heat treatment of gray iron are recapitulated to show that the best results in normalizing strained castings are obtained by heating at a temp. considerably below the critical temp., and to make castings more easily machinable they should be softened by heating at a temp. above the critical point, held long enough at that temp. to insure thorough heating, and then cooled slowly at least through the first 100 degrees.

D. S.

Solubility of oxygen in iron or ferrous oxide (oxoferrite, wüstite). C. BENEDICKS AND H. LÖFQUIST. Metallografiska Inst., Stockholm. *Z. anorg. allgem. Chem.* 171, 231-8 (1928).—The diagram given for the system Fe-O (cf. *C. A.* 22, 937) contradicts the fact claimed by Schenck and Dingmann (cf. *C. A.* 22, 566) that the soly. of O is as high as 2.8% (oxoferrite). It is only 0.05%. It has been suggested that traces of Al_2O_3 picked up from the container by Fe_2O_3 would explain the discrepancies. The soly. of O in a pure Fe-O system is so low that it is difficult to admit that this soly. is increased by the presence of foreign matter, MgO for instance.

Equilibrium relations in the reduction, oxidation and carbonization of iron. VI. 7. **Solubility of oxygen in iron.** RUDOLF SCHENCK AND TH. DINGMANN. Westfälische Wilhelms Univ., Münster. *Z. anorg. allgem. Chem.* 171, 239-57 (1928); cf. *C. A.* 22, 2132.—Polemical. Cf. preceding abstr. Sixteen references are given.

A. L. H.

The systems: iron-phosphorus, iron-silicon and iron-phosphorus-silicon. I. New investigations of iron-phosphorus solid solution in the binary system: iron-phosphorus. H. HANEMANN AND H. VOSS. Tech. Hochschule, Berlin. *Zentr. Hütten- u. Walzwerke* 31, 245-8; *Chem. Zentr.* 1927, II, 321.—To explain the difference between the expts. of Stead (cf. *C. A.* 12, 1751), which showed that the ability of solid Fe to dissolve P diminishes with decrease in temp., and data in the literature which show that the limits of soly. of P in Fe are 1.7% P, regardless of the temp., the capacity of solid Fe to dissolve P was investigated. By annealing and quenching of the system: Fe-P, a new line of segregation was drawn, along which the phosphide, Fe_3P , seps. as the temp. decreases. The max. capacity of solid Fe for dissolving P is around 2.5% P at the eutectic temp. The limit of soly. at room temp is around 1.4% P. II. Critical investigation of the binary system: iron-silicon. *Ibid* 2:9-62.—The peritectic equil. of Murakami for the system Fe-Si was confirmed by metallographic expts. The limit of soly. in α -Fe at normal temp. is around 16.8% Si. A crit. survey is made of views expressed in the literature on the 3-phase equil. at 22.5% Si.

C. C. DAVIS

The macrography of steels with high carbon contents. LUIGI LOSANA AND GIUSEPPE BLASICH. Reale Scuola Ingegneria Torino. *Mel. italiana* 20, 211-5 (1928).—Because of the growing use of stainless steels where it is imperative that no defects exist, it is of increasing interest to be able to detect the presence of various structural defects by simple treatment with a reagent. For this reason, 2 steels with high Cr content (a stainless and a silchrome steel) were treated with I-KI, $CuSO_4$, Stead-Le Chatelier cupric reagent, $\frac{1}{2}$ dil. H_2SO_4 and NaCl electrolyte. A 10% soln. of I in 20% KI did not corrode the steels, and even after several days the only effect was a tarnishing. A reagent composed of 10 g. of $CuSO_4 \cdot 10H_2O$ and 100 cc. of 1% H_2SO_4 deposited a strongly adherent coating of Cu, and after 24 hrs. revealed the configuration of the structure. A reagent composed of 1 g. of $CuCl_2$, 2 g. of HCl, 0.5 g. of picric acid, 10 g. of water and 100 g. of 95% EtOH gave better results than the preceding ones, the fiber structure being visible after 1 hr. and very distinct after 3 hrs. Here again, however, the coating of Cu was difficult to remove. At ordinary temps., 15% H_2SO_4 gave excellent results after several hrs. of immersion. With boiling 15% H_2SO_4 the attack was rapid, but the structural details were less evident. With 15% H_2SO_4 contg. 1% Br the attack was immediate, 30 min. was sufficient to attain the desired results, and at 60° 10 min. was sufficient. The effect is best if immediately after the attack the surface is polished with linen and then with Al dust. The configuration may be rendered still more visible by adding $SbCl_3$ in HCl to the dil. H_2SO_4 . With steel as the positive pole in an electrolytic bath of 10% aq. NaCl, a graphite negative pole and with 4 v., the attack was rapid, the fiber structure becoming visible after 10 min. and completely delineated after 30 min. Addn. of NaI or NaBr to the bath did not improve the effect. To obtain rapid results, and a pattern in which the true structure is plainly visible, in all details, it is recommended that the attack be made with 15% H_2SO_4 contg. 1% Br at 50-60°, immersion being for less than 10 min. The electrolytic method described above is too slow.

C. C. DAVIS

Roman damascus steel. BERNHARD NEUMANN. Tech. Hochschule, Breslau. *Arch. Eisenhüttenw.* 1, 241-4(1927); *Stahl u. Eisen* 47, 1695-6.—Many of the swords in the Nydam discovery show a damascene structure, 3 kinds of the welded (fluted, angular, blooming) being identified. The art of hardening steels was known to the Romans, since a microscopic examn. of the edges of some show the troostite-martensite structure. Hitherto, this structure could seldom be shown, as the martensite goes over into a more stable form in the course of time. Photographs illustrating the 3 types of swords and their microstructure are given.

J. BALOZIAN

Investigation of the rough steel from the "La Tène" time. H. HANEMANN. *Arch. hem. farm.* 2, 115-9(1928).—The metallographical investigations of the rough steel from the first centuries B.C. have shown its excellent qualities. Cementite present in this steel was found unchanged during 2000 years in the earth though it is usually regarded as a metastable system Fe-C.

JAR. KUCERA

Experimental investigation of plastic deformations (in mild steel). P. A. VÉLIKHOV AND N. P. STCHAPOV. Inst. Ingénieurs Transports, Moscow. *Rev. métal* 25, 299-311(1928).—Microscopical investigation of the structure of mild steel (0.2% C) angle-iron under increasing loads led to the following conclusions: The presence in the metal of grains more or less oriented in the same direction and the relatively low resistance to slippage around the contour of the grains resulting therefrom are considered to be decisive factors in the appearance of the first visible deformation. The presence of a harder constituent, even in minute proportion, plays an important part in the mode of plastic deformation, as its presence offers greater resistance to slippage. Long before breaking occurs, permanent deformation acquires (at least at the surface of the test piece) a character which cannot be explained solely by slippage along the crystallographic planes, but which requires that fragmentation be brought into play. The study of plastic deformation should be used as a complementary method in investigating the quality of metal; and, more particularly, the presence of a large no. of grains more or less oriented in the same direction can very easily be detected by observing the lines of slippage. Lorenz' app. for recording micro-deformations of the cryst. grains which occur at the surface of the test piece in the course of the test is described.

A. PAPINEAU-COUTURE

Tempering changes in carbon steels. R. HAY AND R. HIGGINS. *J. Roy. Tech. Coll. (Glasgow)* 1927, No. 4, 62-76.—The manner in which tempering temps. and "aging" are related to the phys. properties of quenched steels was studied. Since slow changes occur in the phys. properties of steels even at ordinary temps. it is pointed out that at elevated temps., where these transformations are more rapid, the time of tempering (soaking) is as important as the temp. of tempering. Working with samples of a low-C steel (C 0.26, Si 0.1, S 0.028, P 0.009, Mn 0.6%) which had been water quenched from 1000° and then tempered at various temps. up to 600°, the authors found irregularities in the phys. property-temp. of tempering curves at approx. 100°, 250° and 350°. The results of measurements of the following phys. properties of the samples are recorded: Brinell hardness, Charpy impact test, proportionality limit, max. stress, per cent elongation, reduction in area, Young's modulus. The influence of time upon the stability of the various structures found in quenched steels was investigated by means of the Brinell hardness and sp. vol. measurements. Samples were quenched from 14 temps. between 400° and 1150°; the phys. properties were detd. and then redetd. after "aging" for 2 months. All the samples quenched at 650° and below showed an increase in hardness and sp. vol. after 2 months. This is thought due to a deposition of finely dispersed carbide from soln. in α -iron. Specimens quenched from between A_{c1} and 900° show a continuous increase of hardness with temp. Above 900° the hardness falls off because of the increased amt. of retained austenite with increasing quenching temp. Because of marked changes in hardness, sp. vol., etc., in steels quenched from 650° the authors ran a series of Izod impact tests on samples of the above steel quenched from near 650°. The results substantiate those obtained by the other methods. Expts. with 2 samples of steel lower in C (0.025 and 0.129%) revealed age-hardening properties similar to those possessed by the steel first studied. The 0.025% C-steel, when quenched from 1000° and tempered at various temps., showed only a marked increase in hardness at 75°. An explanation of the irregularities noted at about 100°, 250° and 350° is offered. It is suggested that the change at 100° is due to the decompn. of the solid soln. of Fe₃C in α -iron. The change at 250° is attributed to the decompn. of residual austenite in the quenched specimens. The 350° change is accounted for by the fact that all the remaining austenite does not transform immediately to martensite and then to troostite, but that the change is periodic and takes a certain time to go to completion.

WILLIAM F. EHRET

Thermal expansion of some nickel steels. PETER HIDNERT AND W. T. SWEENEY. Bur. of Standards. *Phys. Rev.* 29, 911(1927).—Coeffs. of expansion and critical temps. are given for 5 Ni steels contg. from 36 to 42% Ni. Those contg. 38.4% and 42.2% Ni have lower coeffs. of expansion than invar in the range 20° to 500°. W. W. S.

Manufacture and characteristics of silicon steels. I. C. VOLLMANN. *Stahl u. Eisen* 48, 817-9(1928). II. H. KOPPENBERG. *Ibid* 819-22.—Two separate reports on plant experiences with Si steels. J. A. SZILARD

High-speed steel. J. S. GLEN PRIMROSE. *Roy. Tech. Coll. Met. Club J.* 1927-8, No. 6, 29-34.—The heat treatment usually recommended for high-speed tool steels is described and the phys. metallurgy for each of the steps involved is given at some length. Eight photographs are included, showing the microstructure of 18% W high-speed steel as cast, annealed, air cooled from fusion, rolled rod annealed, quenched from a temp. just short of fusion, over-heated and restored to the properly hardened state. DOWNS SCHAFF

Quantitative spectrographic analysis of refined steels. K. KELLERMANN AND O. SCHLIESSMANN. Bergakad. Clausthal and Univ. Jena. *Metallbörse* 17, 1069-70, 1125-6; *Chem. Zentr.* 1927, II, 630.—The visible region of the spectrum has not been recognized as particularly useful for the quant. analysis of refined steels. Comparative photographs of the visible region were taken, and a greater no. of previously unknown sensitive lines were established for W, V, Sn, Mo and Cr. The app. is described and the application of the method is shown for 2 refined steels. The influence of the C used for electrodes is discussed, and adsorption phenomena on the C electrodes are described. C. C. DAVIS

The development of high-quality structural steel. KOPPENBERG. *Z. Ver. deut. Ing.* 72, 918-20(1928).—A brief account of the development and uses of Ni steel (limited by the cost of Ni), low-Si steel, special C steels, etc., leading up to "Steel 48." Steel 48 (1923) had 0.25-0.35% C, 0.5-0.7% Mn, a tensile strength of 48-58 kg./sq. mm., an elastic limit of 29-32 kg./sq. mm., an elongation of 18-23%, and could be made in the open-hearth furnace or converter. It found application in bridges, ship-building and railroad work. Si-steel (1925) is a better material for such uses. It is a high Si-steel, low in C, with a high elastic limit (36 kg./sq. mm.), a tensile strength of 50-64 kg./sq. mm. and an elongation of at least 20%. Its use permits loads 50% greater than could have been used with structural steel in the "nineties," and about 30% greater than with steel 48. It requires great care in prepn. and treatment, must be made in a special open-hearth (Bosshardt) furnace, and consequently has a relatively high cost. Its quality, however, makes it indispensable in certain types of construction, such as bridges, elevated structures for railroads, railroad cars, ships, etc. W. C. EBAUGH

Development of a high-quality structural steel. E. II. SCHULZ. *Stahl u. Eisen* 48, 849-53(1928).—Si steel has little resistance to corrosion, but it can be improved by the addn. of Cu. This, however, does not change the fact, that the manuf. of Si steel is a very difficult process. Therefore the development of high-quality structural steel was tried, which does not have a high Si content. The new steel contains C 0.15, Si 0.25, Mn 0.80, Cu 0.5-0.8 and Cr 0.4%. The cost of the raw materials for this Cu-Cr-steel is higher than that for the Si steel; on the other hand the waste during the manuf. is lower. The new steel has practically the same strength as a 1% Si steel; its av. limit of elasticity is 38 kg./sq. mm.; the tensile strength is 54 kg./sq. mm. and the elongation 23%. A special advantage of the new Cu-Cr-steel is that the strength, particularly the limit of elasticity, does not change much with the conditions during rolling. The resistance to corrosion of the new steel is much higher than that of a 1% Si steel or a Cu-C-steel. J. A. SZILARD

The influence of heat-treating soft steel ingots before rolling on the structure and tensile properties of industrial steels. H. BITTER. *Arch. Eisenhüttenw.* 1, 371-8 (1927).—The ingots are made by blowing crude Thomas Fe in a converter, rolling one set immediately after pouring, while another is first cooled and reheated. Liquation is found to be greatest in the reheated ingots, there being present, also, greater differences in compn. in these. S prints, Oberhoffer- and picric acid etchings are made to det. the influence of heat treatment on the primary and secondary structures of the steels. The primary etchings show the presence of a P-rich zone between the surface and the core of the reheated ingots, attributable to the rolling. From the secondary structure it is seen that the grains of the reheated steels are larger than the cooled ingots, this difference being present principally in the interior of the ingot. The steels which were not reheated were marked by greater nick-hardness. Tests on 100 ingots, which were a part of the plant production, confirmed the above results. J. BALOZIAN

The influence of cobalt, vanadium and manganese on some properties of tool steel.

ROBERT SCHERER. *Arch. Eisenhüttenw.* 1, 325-9(1927); *Stahl u. Eisen* 47, 2035-6.—A study of the effect of increasing amts. of Mn, V, V and Si, Co, Co and V on the hardness, vol. changes on hardening and ability to hold their cutting edge of eutectoid steels. The positions of the arrests of the various steels show that Co and V exert no special influence on A_1 and A_c , while Mn sharply lowers the former and raises the latter. Steels alloyed with Co are particularly insensitive to various hardening conditions, especially to over-heating. These steels also show the least vol. change on hardening and the least hardening sensitiveness. The highest cutting power is shown by steels contg. 0.3-0.7% V; it is strongly raised in Co-alloyed steels, but remains const. with increasing Co. Steels alloyed with Co and V show on hardening, greater insensitiveness, less vol. change, a higher multi-hardness no. and the highest cutting power. Because of these properties they are the most suitable tool steels. J. B.

Corrosion of steels at high temperature. LUIGI LOSANA AND GIULIO REGGIANI. Reale Scuola d'Ingegneria Torino. *Notiz. chim.-ind.* 3, 271-5, 346-52(1928).—Systematic expts. were carried out to det. the corrosion of various types of common and special steels which occurs at temps. from 400° to 1000° in air. Where the expts. were similar to those of Hatfield (cf. *C. A.* 21, 2245) his results were confirmed. In no case could the progress of the corrosion be expressed as a linear function, and the greater the rate of oxidation the more did this deviate from a linear function. With all steels there was a very pronounced increase in the corrosion from 800° to 900°, and still more so between 900° and 1000°. Even the least readily oxidized steels, which were relatively little attacked up to 900°, underwent an intense corrosion at 1000°. This disproportionate increase in corrosion at the highest temps. was most marked in steels which withstood oxidation best at low temps. Thus homogeneous Fe showed 2.4 times as much corrosion at 1000° as at 900°, whereas a steel contg. 23.5% Ni showed 12.6 times as much. With respect to the influence of individual elements, Ni above 3% increased the resistance to oxidation, while Cr gave the best results, especially above 1.5-2%. Cr-Ni steels were particularly resistant when the C content was neither very low nor very high. Though cementation steels with less than 0.15% C were not resistant, steels of similar compn. except for a C content of 0.30-0.40% were extremely resistant. In all cases tempering greatly increased the resistance to oxidation. Exhaust gases contg. N, O, CO₂, CO, H₂O and traces of hydrocarbons had in general a more intense oxidizing action than air at the same temp., though with extremely resistant steels there was little difference. Qualitatively the progress of the corrosion as a function of time and temp. was the same in each case. The greater corrosion with the waste gases is attributed to the simultaneous action of carburization, cementation and oxidation caused either directly by atm. O in excess present in the exhaust gases, or indirectly by CO₂. Macroscopic examn. of valve sections showed a difference in the fibrous texture of valves which had been used for a long time from the texture of new valves, because of the annealing undergone. There was a zone of corrosion resulting from carburized products, accompanied by inclusions of oxides. In the great majority of valves this zone was removed by the continual shock and the seat appeared hollowed out to a considerable depth. Comparative expts. showed that steels rich in Ni and rich in Cr have a high resistance to oxidation by air or by exhaust gases. Steels with a high W content are also resistant but less so than Ni and Cr steels. In general, steels which lost their temper only at high temps. showed the most resistance to corrosion. The best results were obtained with Silchrome steel and a steel contg. 13.84% Cr. Steel contg. 25% Ni gave good results, but not so good as those above. Even with these steels, the resistance was high only up to 900°, above which temp. range, corrosion was rapid. Steels contg. around 4% Ni and less Cr were very resistant after they had been tempered. A bibliography of 19 references is appended.

C. C. DAVIS

Yield point in steel at various temperatures. J. MUIR. *J. Roy. Tech. Coll., Glasgow* 4, 14-23(1927).—The yield points at various temps. have been detd. for mild steel in the form of wire. The temps. required were obtained by electrically heating the wires. The rate of extension at a yield point is very greatly increased by increase of temp., while the phenomenon of the yield point (*i. e.*, the extension of the wire by jerks and not by creeping) disappears entirely at 250°, in opposition to the observations of Lea and Crowther (*C. A.* 9, 285).

B. C. A.

The fatigue-resisting properties of 0.17 per cent carbon steel at different temperatures and at different mean tensile stresses. H. J. TAPSELL. *J. Iron Steel Inst.*, May, 1928 (advance copy), 13 pp.; *Engineering* 125, 567-8(1928).—Fatigue expts. were carried out on normalized 0.17% C steel with a Haigh machine under direct pulsating stresses applied at the rate of 2400 cycles per min. Fatigue limits were detd. at different

mean tensile stresses up to 500°. Above 300° fatigue limits based on 10' alternations of stress are dependent on the rate of alternations applied. At temps. up to 200° (or 250°) the practical fatigue limits under different mean tensile stresses are dependent on the static limit of proportionality or yield point of the material. These practical fatigue limits do not alter appreciably at temps. up to 200° but above this temp. depend on a suitable proof stress.

A. W. COFFMAN

Heat-resisting steels. II. Mechanical properties. W. H. HATFIELD. *J. Iron Steel Inst. May, 1928* (advance copy), 22 pp.; *Engineering* 125, 589-90, 622 (1928).—Thirteen tables give the results of analyses and tensile tests on wrought iron and various steels. These tables illustrate the following points. Wrought iron pulled in tension at 800° gives a value as low as 2.03 tons per sq. in. while 0.15 C steel gives a value of 4 tons. Modern high-tensile hardened and tempered alloy steels of Ni, Ni-Cr, Ni-Cr-Mo, Cr-V give a max. value at 800° of 7.68 tons per sq. in. Si-Cr heat-resisting steels gave at 800° only 4 to 6 tons while high-speed tool steel ranged from 8 to 10.5 tons per sq. in. Co-Cr gave a value of 13 tons per sq. in. The improvement in tensile strength on addn. of Cr is only obtained with steels contg. considerable C (0.54 C). Addn. of Ni up to 36.5% gives a tensile strength at 800° of only 7.85 tons per sq. in. Combinations of Ni-Cr-C in steels gave somewhat higher results. The addn. of W to Ni-Cr steels gave greatly increased values of tensile strength at 800°, some being as high as 22.5 tons per sq. in. Mo and Si increase the strength of Ni-Cr steels at elevated temps. and C plays an important part in regulating the strength. An explanation is offered for the action of some elements in increasing the tensile strength at high temps.

A. W. COFFMAN

Results of using copper-bearing steel in freight cars. J. S. UNGER. *Railway Age* 84, 1060-2 (1928).—Comparative service tests by the Bessemer and Lake Erie R. R., of 100 hoppers and 100 gondolas built in October, 1914, using Cu-bearing steel in one half of the body and plain steel in the other half of the same car, show loss in thickness from corrosion of the Cu-bearing steel to be between 55 and 61% of the plain open-hearth steel. Paint adheres much better to Cu-bearing steel in a car body than it does to plain open-hearth steel.

R. C. BARDWELL

The effect of silicon on tungsten magnet steel. J. SWAN. *J. Iron Steel Inst. May, 1928* (advance copy), 9 pp.; *Engineering* 125, 554-5 (1928).—The "spoiling" of W magnet steel (Si 0.13%) by annealing above the Ac point is due to the gradual formation of free W carbide, which is only slightly sol in austenite so that the steel loses available C and W. W carbide segregates on prolonged soaking but is retarded by a Si content of 0.25%. Si up to 0.50 has no harmful effect. Conclusion: Increasing the amt. of Si does not eliminate the spoiling effect produced by reheating of the steel for forging or rolling and it is therefore necessary to use a max. reheating temp. for rolling (1200°) to obtain the best results. One % Si reduces the loss of coercive force on annealing by 1/2 but the other magnetic properties are made more inferior by such a practice.

A. W. COFFMAN

Heterogeneity of steel ingots. ANON. *J. Iron Steel Inst. May, 1928* (advance copy), 147 pp.; *Engineering* 125, 583-4 (1928).—A résumé of the report by the Comm. of the Iron and Steel Institute on the Heterogeneity of Steel Ingots. In the design of ingot molds 5 points must be remembered, namely: freedom from cavity, suitability for and ease of further working, stresses set up on cooling, elimination of planes of weakness and layout of segregate. The presence in the ingot of oxides and silicates, S and P gases may influence heterogeneity. A study was made of Ni, Ni-Cr, Ni-Cr-Mo steel ingots. The percentage variation of C, P and S in different parts of the ingots increases as the size of the ingot increases. The presence of Ni and Cr tends to diminish segregation. A study was also made of C steel ingots other than killed as well as of non-piping or semi-killed steel.

A. W. COFFMAN

Sink-head ingots. R. S. HARDEN. *Am. Ry. Eng. Assocn. Proc.* 29, 1075-1109 (1928).—Extended data and charts covering chem. content of steel used in rails indicate that waste of material from the top was reduced by the sink-head method from 22 to 17% and rejections were fewer in this rail by 2%. The annual av. no. of failures in sink-head rail per 100 miles of track was 1/3 less than ordinary rail.

R. C. B.

Steel rails from sink-head and ordinary rail ingots. GEORGE K. BURGESS. *Am. Ry. Eng. Assocn. Proc.* 29, 1110-74 (1928).—Extensive data covering chem. compn., type of treatment, and phys. properties are submitted and indicate a decided superiority of the sink-head ingot over comparable ordinary ingots of steel used for rails.

R. C. BARDWELL

Contribution to the study of the solution of aluminum and its alloys in acids. X. WACHÉ. *Rev. métal.* 25, 331-46 (1928); cf. *C. A.* 19, 2629.—The results obtained

(which are given in the form of tables, with several photomicrographs) show that soln. of ordinary Al in HCl comprises 2 stages, both of which depend on the physicochem. state of the impurities, Fe and Si. The rate of soln. increases progressively during the 1st stage, which is better characterized by the depth to which the metal is dissolved than by the time of attack. The induction period depends not only on the Al, but also on other exptl. factors which are foreign to it, such as concn., temp., etc. The depth to which the metal is dissolved during this stage, on the other hand, is but slightly affected by variations in the phys. or chem. conditions under which soln. is carried out, and depends mainly on the physicochem. condition and structure of the Al; it varies with the content of impurities, and especially with their distribution; it decreases when the impurities are most uniformly distributed, the best distribution being obtained either by rapid solidification or by rolling. During the 2nd stage, assuming that the concn. is const., soln. takes place at a definite rate, which is independent of the size of the grains, but which varies with the compn. of the metal, the rate at which it solidified, the degree of annealing and of cold-hardening. The lowest rate of soln. is obtained with the purest Al. The rate of solidification intervenes to the extent to which it detrs. the distribution of the free impurities throughout the mass of metal; and, as could be foreseen from the electrochem. theory, a more uniform distribution of impurities through rapid cooling frequently increases the rate of soln. Annealing decreases or increases the rate of soln. according as it causes soln. of part of the impurities or ppts. them. The effect of a given annealing treatment can be predicted to a certain extent by means of the diagrams of the alloys which Al forms with its chief impurities. Cold-hardening reduces the rate of soln. of ordinary Al in HCl, which appears to be due to the dislocation of the network formed by the impurities throughout the metal.

A. PAPINEAU-COUTURE

Antimony-tin alloys. W. BRONIEWSKI AND L. SŁIWOWSKI. *Ecole Polytechnique, Varsovie. Rev. métal.* 25, 312-21(1928); cf. *C. A.* 22, 3125.—After a brief review of previous work on Sb-Sn alloys, bringing out the contradictions between them, B. and S. describe the results of their investigation of the elec. cond., variation of resistance with temp., thermoelec. power and its variation with temp., soln. potential, expansion coeff. and its variation with temp., hardness, and fusibility of such alloys, from which they conclude that the only compd. formed is Sn_3Sb_2 , which forms limiting solid solns. with Sb. At ordinary temp. Sn_3Sb_2 forms mixts. with the solid soln. contg. 8% Sb, while the limiting solid soln. of the compd. (about 53%) forms mixts. with the solid soln. contg. 90% Sb. The results are given both graphically and in tabular form.

A. PAPINEAU-COUTURE

Hardening of aged silver-aluminum alloys. M. HANSEN. *Naturwissenschaften* 16, 417-9(1928).—The self-hardening properties of Al-Ag alloys were studied in 12 specimens with 0.45 to 11.8% Ag (the Al contained 0.097% Si and 0.158% Fe). Blocks of 20×35 mm., 120 g., were cast and hot forged down to 10 mm., heated at 525° for 5 hrs. and chilled in ice-water. The aging was done in oil baths at 100°, 150° or 175° and the Brinell hardness (5 mm. ball, 62.5 kg. pressure, 30 secs) detd. At 100° the max. hardness had not been reached after 6 weeks; at 150° it was obtained in 5 to 7 days, at 175° in 1 to 5 hrs. The alloy with 0.45% Ag hardened little and only at 100° and 150°; it shows that the soly. of Ag in Al below 150° is less than this percentage. The optimum hardening temp. is considered to be between 150° and 160°; the ratio between max. hardness and initial hardness increases from 1 up to 6% Ag. The abs. value of the hardness is lower for these alloys than for Cu-Al alloys; it runs from 20 up to 78 (Brinell) for material aged at 150° for 5 days, the initial Brinell value being for the same samples from 19 to 48.

B. J. C. VAN DER HOEVEN

X-ray analysis and crystalline structure of cadmium-silver alloys. III. G. NATTA AND M. FRERÉ. *Reale Politecnico Milano. Atti accad. Lincei* [6], 7, 406-10(1928); cf. *C. A.* 22, 1564.—The present work proves it necessary to revise existent data obtained by thermal analysis. The alloys were rapidly solidified and tempered, and were examd. by the powder method. There is a field of α solid soln. of Cd in Ag, which has a lattice like the latter, but becoming more and more deformed, according to the Vegard law, up to 35% Cd. The α phase is present in alloys contg. 0-45% Cd. The dimension of the elementary cell increases from 4.07 to 4.15 A. U. A compd., AgCd , which has a cube-centered lattice, and is capable of forming β solid soln., is present in alloys contg. from 47 to 55% Cd. Its elementary cell, with dimension increasing from 3.32 to 3.34 A. U., contains 1 mol. Its calcd. d. is 9.97-9.82. Alloys contg. 55-65% Cd are composed of solid solns. of a new phase which has a complex structure similar to the centered lattice, with cubic elementary cell of 9.96 A. U. contg. 52 atoms, i. e., 4 mols. of the compd., Ag_5Cd_8 . From 65 to 95% Cd, the structure is of the simple,

compact, hexagonal type with $c/a = 1.58$, and with its elementary dimension varying from 3.04 to 3.09 A. U. These alloys represent ideal solid solns. of Cd and Ag in the compd., $AgCd_3$. The dimension of the elementary cell, probably a multiple of 3.07 A. U., could not be detd. precisely because the Cd and Ag atoms have at. wts. so little dissimilar. For the same reason it was difficult to det. whether in these alloys there is a regular distribution of atoms of the solute. Alloys contg. 95–100% Cd are composed of a soln. of Ag in Cd, with the lattice of Cd. On annealing, transformations were observed only with β alloys. The compd. $AgCd$ is dimorphous, and below 420° is converted into a compact hexagonal modification, with $c/a = 1.62$ and $a = 3.01$ A. U. At temps. below 200° , some solid solns. of $AgCd$ become unstable and are transformed into a mixt. of the α and γ phases. There is a great similarity between the cryst. structure of Cu-Zn and $AgCd$ alloys, as shown by the fact that all phases present in tempered $AgCd$ alloys have lattices similar to those of brasses. Such similarity has an analogy in the homologous position occupied in the periodic system by Cu and Zn with respect to Ag and Cd.

C. C. DAVIS

Alloys of iron with low percentage of titanium. HANS MATHESIUS. *Stahl u. Eisen* 48, 853–8(1928).—Exptl. melts of steel made in an elec. furnace and contg. 0.38 to 3.21% Ti were prepd. Next a larger hatch of a steel contg. 0.2% Ti was prepd. by adding the Ti in form of $FeTi$ with 18.9% Ti. The addn. of Ti has a desulfurizing effect; the tendency for segregations is also decreased. Microscopical investigation shows a ferrite-pearlitic structure, with a few small red colored crystals of Ti_3N_2 and Ti_2C . The mech. characteristics show an increase in elastic limit of 80%; and in tensile strength of 50–55% as compared with ordinary C steels. The impact strength is also higher.

J. A. SZILARD

The effect of heat treatment on some mechanical properties of 86:4:6:3:1 copper-nickel-tin-zinc-lead alloy. ROBERT J. ANDERSON. *Am. Metal Market* (Mag. Sect.) 35, 1–3, 14(1928); cf. C. A. 22, 2913.—This is the last of a series of 8 articles on the effect of various heat treatments on the mech. properties of sand-cast Cu base alloys of the brass and bronze type. The alloy was sand-cast into suitable tensile-test bars, annealed for various periods in the range 400 – 750° , and air cooled. Annealing has in general a harmful effect on strength and elongation. Annealing at 650° has a very deleterious effect on the ductility and strength. The alloy shows rather wide variations in hardness for a given treatment, indicating non-homogeneity. It is evidently of the solid-soln type. Ni-bearing complex bronzes appear to have possibilities for considerable use in place of certain standard alloys, but there appears to be no particular field in which they excel. Photomicrographs and a bibliography are included.

E. G. R. ARDAGH

Nickel: an account of its alloys and its uses. ALFRED C. STURNEY. *Mining Mag.* 38, 341–7(1928).—The properties and uses of Ni, Ni steel, and all the important Ni alloys are discussed.

Effects of the addition of various elements on the properties of alloy steels. P. FROGER. *Aciers spciaux* 2, 238–51(1927); *Chimie et industrie* 19, 851–2(1928).—A review of the changes in properties of the Fe-C alloy brought about by the metals generally used in alloy steels: Ni, Cr, Mn, W, Co, V, Mo, Si and Al.

A. P.-C.

The secondary hardening of alloy steels. J. H. ANDREW. *Roy. Tech. Coll. Met. Club J.* 1927–8, No. 6, 7–8.—A Ni-Cr steel contg. 3.6% Ni, 1.65% Cr and 1.2% C had its Brinell hardness value raised from 187 in the quenched sample to above 500 by tempering at 650° for 15 min. A. considers the steel to cool from the quenching temp. to ordinary temp. without undergoing any transformation and tempering above 400° causes carbide of Fe to be removed from soln., leaving a solid soln. of a compn. that under ordinary conditions of cooling gives rise to a crit change at 150° . This transformation is the γ - α change, and the net result is the formation of martensite.

D. S.

The development of the electric arc welding process. A. R. ALLARD. *Westinghouse Co. Elec. J.* 25, 423–7(1928).—A review

C. G. F.

The soldering and welding of aluminum. G. MEIKLE. *Roy. Tech. Coll. Met. Club J.* 1927–8, No. 6, 41–2.—The application of solder to Al and high Al alloys is justified when used for repairing small defects in castings but is not recommended where exposure to atm. conditions is contemplated, since in moist air electrolytic corrosion is set up and very severe corrosion takes place at the junction of the solder and the Al. Welded Al joints are necessarily of somewhat uncertain quality and dependable results can only be obtained by highly skilled welders.

DOWNS SCHAAP

Pipes in relation to eutectic composition. BERNHARD OSANN. *Giesserei Z.* 15, 49–51(1928).—It is shown that preheating of the mold does not alone suppress the formation of pipes. Eutectic alloys do not "pipe". It is considered that the formation

of a pipe space is due to the diminution in vol. occurring in the change from the liquid to the solid and to the formation of crust from the surface of the casting to the interior, as solidification proceeds. Both actions take place simultaneously. Without the latter action pipe formation is missing, only a diminishing of the outer dimensions being apparent. Thus, pipes occur only when the melt is viscous, for when the liquid metal flows easily the spaces formed during the shrinking are immediately filled. A method of testing for pipes is given, depending on the fracturing of the casting.

J. BALOZIAN

Corrosion of zinc roofing. H. F. RICHARDS. *Metal Ind.* (N. Y.) **32**, 633-4 (1928).—From analyses of the corrosion products from Zn roofing it is concluded that the corrosion is due to the S compds. in the atm.

B. E. ROTHLEI

Bureau of Standards soil-corrosion studies. I. Soils, materials and results of early observations. K. H. LOGAN, S. P. EWING AND C. D. YEOMANS. *Bur. Standards, Tech. Papers* **1928**, No. 368, 447-554.—Test pieces of various metals and coated metals were buried in soils of different compns. Examns. of specimens removed after 1, 2 and 4 yrs. permit no definite conclusions to be drawn regarding the corrodibility of different metals of similar groups. The work thus far shows that the type of corrosion of a group is influenced by the nature of the soil. Most soils are but slightly corrosive. In many cases the corrosion rate and pitting rate fall off with time. Galvanized pipes are in general more resistant to corrosion than untreated pipe. The corrosiveness decreases with increasing wt. of Zn coating. Some soils corrosive to steel cause the formation of a protective film on Zn which affords good protection. Thin bituminous coatings yield insufficient protection against severely corrosive soils, probably because of the poor methods available for application. Pb and Zn fail by pitting in some soils and Al is rapidly attacked. Cu and high-Cu alloys are generally resistant in all soils. The investigation has not proceeded sufficiently far to warrant definite conclusions to be drawn regarding the relative merits of metals of the same type.

Concentrating minerals by flotation. GUGGENHEIM BROTHERS. Fr. 634,124, May 10, 1927. The mineral is submitted in the form of a pulp or mud to a flotation operation in the presence of an alkyl, aryl or aralkyl deriv. of a thiocarboxylic acid, such as ethyldixanthogen or xanthic anhydride. Fr. 634,125 and Fr. 634,126 give further details of a similar process. Fr. 634,127 describes a similar process in which a metallic xanthate and an acid chloride are used.

Agitator and sluice box apparatus for concentrating ores. F. H. NASH. Brit. 282,298, June 21, 1927.

Riffle apparatus for concentrating precious metals. WILLIAM A. HUELSDONK. U. S. 1,679,035, July 31.

Ore separation. ANDREW T. SWEET (one-fourth each to William G. Rice and Herman Gendlach and one-tenth to Philip B. Woodworth) U. S. 1,678,884, July 31. A stream of ore such as one contg. Cu, Ag, Au or Zn is passed across a beam of light, and the ore is sepd. by a device controlled by a Se cell according to variations in light reflection of different masses in the ore stream. An app. is described.

Treating ores before leaching. F. DIETZSCH. Brit. 281,741, July 7, 1926. Oxidized ores such as those of Cu or Zn are heated, or roasting of the ore is effected, with not more than 2% of an alkali metal or alk. earth sulfate. The process may also be applied to Au ores before extn. with cyanide.

Apparatus for sintering sulfide ore concentrates. HENRY J. STEHLI. U. S. 1,680,345, Aug. 14.

Treating copper ores. JOHN C. MOULDEN and BRUCE TAPLIN (to Metals Production Co. of North America, Inc.). U. S. 1,679,337, July 31. Ore is heated with solid carbonaceous material such as coal or charcoal and with a halide such as NaCl at a temp. lower than the m. p. of Cu but sufficiently high to cause reaction (suitably about 400°). This treatment causes deposition of metallic Cu on the exterior of particles of the material. An app. is described. Cf. C. A. 21, 2868.

Treating copper sulfide ores. FERDINAND DIETZSCH. U. S. 1,679,294, July 31. The ore is mixed with not more than 2% of an alkali sulfate such as Na₂SO₄ and roasted; the values may then be extd. by dil. H₂SO₄ soln.

Treating iron ores. GRANULAR IRON COMPANY. Fr. 633,870, May 4, 1927. An app. is described for treating iron ores in which rotating or slightly inclined furnaces are used.

Preparing iron ore flue dust for smelting. FRANK F. MARQUARD. U. S. 1,680,107, Aug. 7. Ammonia still waste liquor is mixed with the flue dust, to agglomerate the fine particles. Blast-furnace slag also may be added.

Roasting and reducing iron ores or other ores with circulating heated gases. BROR CHRISTIANSEN. U. S. 1,680,861, Aug. 14. Ore is passed successively in a substantially horizontal direction through preheating, roasting, prereluction and final reduction zones of a channel furnace (which is described); in the final reduction zone the ore is subjected to the reducing action of circulating reducing gases, these gases are recarbonized outside the channel furnace in alternately operative recarbonizing furnaces; the excess of circulating gases is drawn off and partly burned in the inoperative recarbonizing furnace by a regulated air supply, for reheating the furnace; gases formed by the partial combustion are supplied to the prereluction zone and finally subjected to further combustion in the roasting zone. The process is suitable for producing spongy Fe.

Platinum from ores. J. W. MELLOR. Brit. 282,543, Nov. 18, 1926. Pt is extd. from ores by treating the ore with a molten metal such as Pb or Pb contg. a small

proportion of an alkali or alk. earth metal, which dissolves Pt. The process may be made continuous.

Treating zirconium ores. RHENANIA-KUNHEIM VEREIN CHEMISCHER FABRIKEN A.-G. Brit. 282,023, Dec. 13, 1926. Zr ore is mixed with an alk. earth carbonate, oxide or hydroxide, and with a halogenide of an alkali or alk. earth metal and sintered at a temp. of about 1200° without C or carbides to produce Zr oxide sol. in acids. The presence of steam facilitates the reaction and enables it to take place at somewhat lower temps. CaCO_3 may be used with fluorspar or CaCl_2 .

Reclaiming light metals from dross. THERON D. STAY and CHARLES O. TESSIER (to Aluminum Co. of America). U. S. 1,679,385, Aug. 7. An app. is specified comprising a device such as a special stirrer for reducing highly heated dross to a finely divided condition to liberate molten metal entrapped in the dross, and means for agglomerating and solidifying the liberated molten metal. Cf. C. A. 21, 2246.

Obtaining volatile metals from sulfides. HENNING G. FLODIN and EMIL G. T. GUSTAFSSON (Flodin to Harry Broady). U. S. 1,680,098, Aug. 7. Finely divided metallic Fe is used in making briquets in admixts. with finely divided ZnS ore or other material contg. sulfides which can be reduced by Fe; these briquets are heated in a closed elec. furnace to effect reaction and liberation of the metal from the sulfide.

Extracting gold from sea water. BORIVOJ CERNIK and BOHUSLAV STOKES. Fr. 633,998, May 6, 1927. A screen or partition on which is a removable layer of one or several substances capable of combining with the gold or of retaining it, is placed so that the sea water passes through.

Apparatus for filtering solutions from copper slimes, etc. WILLIAM M. MORRISON (to American Smelting and Refining Co.). U. S. 1,678,704, July 31.

Refining metals. RICHARD WALTER. Fr. 631,436, May 14, 1927. When alkali compds. are used in the refining of molten metals, their normal speed of decompn. is slackened by the addition of CaF_2 in from 1 to 38%.

Metal coatings. SOC. ANON. ACIÉRIES ET FORGES DE FIRMINY. Fr. 633,691, Sept. 7, 1926. See Brit. 277,307 (C. A. 22, 2332). Metals are protected against the action of N compds. by thick Ni electroplating.

Coating metal plates with aluminum. FRANZ JORDAN. U. S. 1,679,308, July 31. Al strips are rolled onto both sides of other metal such as Fe, to form a firmly adherent coating. Various mech. details are described.

Plating metals. W. E. WATKINS. Brit. 282,624, Dec. 24, 1926. The foundation metal, e. g., a sheet of ferrous metal, is coated with a mixt. of finely divided plating metal such as Cu or a readily reducible compd. of the metal and a reducing medium, e. g., C and asphaltic hydrocarbons, and the materials are passed through a furnace so that an adherent coating of the coating metal is formed on the foundation metal and a layer of oxide is formed on the coating metal. The oxide may then be removed by pickling.

Detecting minute holes in metal plating, etc. K. FITSCHNER (to American Chain Co.). Brit. 282,621, Dec. 22, 1926. A strip of paper or other suitable material is applied to the surface to be tested after having been treated with a substance which will react chemically with the base and form a visible record either directly or after development; e. g., paper may be treated with an aq. soln. of agar agar, NaCl, $\text{K}_2\text{FeC}_2\text{N}_6$, and EtOH or MeOH, and, on being moistened and applied to a coating of Cu on steel, blue spots appear where punctures reach through to the steel. The test paper may be coated with shellac varnish after the test, to preserve a permanent record.

Mold for casting metals. MARIUS GUYOT (to Aluminum Co. of America). U. S. 1,679,860, Aug. 7. Mech. features, especially relating to molds such as those used for Al or other metals of higher m. p.

Molds suitable for casting aluminum and its alloys. ALLEN B. NORTON and MARIUS GUYOT (to Aluminum Co. of America). U. S. 1,679,869-70, Aug. 7. Structural features.

Multi-part permanent molds suitable for casting metal articles such as aluminum or its alloys. MARIUS GUYOT (to Aluminum Co. of America). U. S. 1,679,861, Aug. 7. Mech. features.

Multi-part permanent molds for casting aluminum and its alloys. GEORGE KOHL (to Aluminum Co. of America). U. S. 1,679,864, Aug. 7. Structural features.

Ingot mold. EMIL GATHMANN. U. S. 1,680,872, Aug. 14. Structural features.

Molds for pig-iron. FELIX QUINN (one-half to Emil Neuhart). U. S. 1,679,876, Aug. 7. Material such as a plate coated with fireclay and lime is embedded in the mold (which may be mainly formed of pig iron) to retard the expansive force of the inner toward the outer portion of the mold wall.

Mold for centrifugally casting of pipe. HEINRICH BURCHARTZ (to Centrifugal Pipe Corp.). U. S. 1,678,633, July 31. Mech. features.

Rotatable low-conductivity mold for centrifugal metal casting apparatus. LUCIEN I. YEOMANS (to A. O. Smith Corp.). U. S. 1,678,929, July 31.

Apparatus for centrifugal casting of hollow metal bodies. JOHANN HOLTHAUS (to Centrifugal Pipe Corp.). U. S. 1,678,641, July 31.

Centrifugal casting of steel pipe couplings. HARRY BLUMBERG and MARTIN A. MIKESH (to A. O. Smith Corp.). U. S. 1,678,931, July 31. The interior surfaces of a metal mold are covered with graphite or ferro-Mn and Al or other suitable substance which will retard the freezing of the molten metal first introduced and form an alloy with the metal.

Casting ingots. JOSEPH A. DURFEE. U. S. 1,678,976, July 31. A partition is placed within an ingot mold so as to divide the mold into inner and outer compartments and metal is poured into the inner compartment and permitted to flow under the partition to the outer compartment. This serves to restrict segregation of metalloids and avoid contact of released gases with the mold wall.

Apparatus for casting metal articles such as steel ingots. JAMES M. NELSON. U. S. 1,679,582, Aug. 7.

Casting ingots of steel, gun metal, bronze, etc. K. HONDA. Brit. 281,992, Dec 9, 1926. To avoid defects in the ingots, a riser or header of the mold is filled with molten slag of about the same or a higher temp. than that of the metal, directly after casting.

Iron castings. KARL SIPP (to Heinrich Lanz A-G). U. S. 1,678,655, July 31. In producing gray iron castings in shapes of widely varying sections having a substantially uniform structure and hardness, casting is effected with a mixt. adjusted to produce under normal cooling conditions a workable gray iron in one of the thick sections and cooling of the metal in the thinner sections is retarded and in the thicker sections, if any, is hastened.

Malleable iron castings. H. A. SCHWARTZ (to National Malleable & Steel Castings Co.). Brit. 282,671, Dec 23, 1926. In producing malleable iron castings, the casting, while still at a temp. above the crit. point or after reheating to such temp., is quenched to room temp. or to a temp. of about 200-300°, the rate of cooling being about 5.5° or more per sec. The casting is then heated to above the crit. temp. (suitably to about 900°) and maintained at that temp. for a sufficient time to effect decompn. of the cementite in the iron, and is then cooled to below the crit. point, held at such temp. for about 30 hrs. and then cooled.

Metallic material for addition to cast iron while molten. PAUL D. MERICA and THOMAS H. WICKENDEN (to International Nickel Co.). U. S. 1,680,161, Aug. 7. An addn. material for molten cast iron baths comprises Ni alloyed with another material such as C, Si and Al in sufficient quantity to lower the m. p. to substantially the m. p. of the cast iron.

Rolling metal plates. GRAFENBERGER WALZWERK GES. and F. HOLZHAUSEN. Brit. 281,944, May 23, 1927. A pack of plates to be cold rolled are welded together at their longitudinal edges to prevent shifting.

Metal box for holding metal articles during carbonizing, etc. EDWARD P. VAN STONE (to General Alloys Co.). U. S. 1,679,510, Aug 7. Sheet metal side plates are mounted in cast metal corner pieces so as to permit free expansion and contraction.

Treating nickel-containing mat or metal. OTTO LELLEP (to International Nickel Co.). U. S. 1,680,155, Aug. 7. A pressure blast of preheated air is applied directly to the molten metal, in an app. which is described. Cf. C. A. 21, 1624.

Furnaces for metals. SOC. REBOURG ET DUPONT. Fr. 634,113, May 10, 1927. To prevent oxidation in the melting of metals when using heavy oils, the metal, as soon as it melts, pours down into an elec. heated chamber away from the oil flame.

Rotary or tilting oil-fired furnace for melting metals. G. REGNAC PAILLE. Brit. 282,627, Dec. 23, 1926.

Regenerative open-hearth furnace. STEWART J. CORT, TIMOTHY BURNS, ROBERT S. A. DOUGHERTY and CHARLES E. LEHR. U. S. 1,680,365, Aug. 14.

Blast furnace construction. BROKEN HILL PROPRIETARY CO. Brit. 282,042, Dec. 9, 1926.

Reversible metallurgical furnace. FRANK B. MCKUNZ (to Open Hearth Combustion Co.). U. S. 1,679,340, July 31.

Cupola furnace. ALPHONSE E. BAILLOT (51% to Archibald Harold Coplan and 49% to Archibald Hymen Coplan). U. S. 1,678,899, July 31.

Furnace (with cupola and fore-hearth) suitable for melting iron. HUGO LUYKEN. U. S. 1,681,043, Aug. 14.

Rotating furnace (with cooled walls) for refining steel, iron or other metals. JUVENAL MAXIMOFF, MARIA S. DE COSTA and ROBERT P. D. KREBS. U. S. 1,681,191, Aug. 21.

Electrically heated furnace for bright-annealing in a protective gas. SIEMENS-SCHUCKERTWERKE A.-G. Brit. 282,079, Dec. 9, 1926. Structural features.

Furnace for use in copper plating ferrous metals. WILLIAM E. WATKINS (to Copper Plate Sheet and Tube Co.). U. S. 1,679,389, Aug. 7.

Furnace suitable for heating, puddling or forging operations. WILLIAM F. WEATHERS. U. S. 1,680,654, Aug. 14.

Furnace for welding bundles of scrap metal, etc. FRITZ MENNE (to Herman F. Hoevel). U. S. 1,680,468, Aug. 14.

Furnace suitable for heating rock drill steels. WADE H. WINEMAN (to Sullivan Machinery Co.). U. S. 1,679,145, July 31.

Built-up vertical zinc retort construction. FRANK G. BREYER and EARL H. BUNCE (to New Jersey Zinc Co.). U. S. 1,680,726, Aug. 14.

Pure iron. H. J. VAN ROYEN. Brit. 282,365, Dec. 14, 1926. In producing pure Fe by a blast or open-hearth refining process, a reductive non-carbonizing gas (suitably a mixt. of CO, CO₂, and N in proper proportions, or a mixt. contg. SO₂ and N) is blown through the metal bath which may be covered with a new layer of slag, after the ordinary refining process. The Fe produced is suitable for the manuf. of alloyed or unalloyed steel. Brit. 282,366 specifies carburizing the Fe thus prepd., by passing satd. hydrocarbons or other carburizing gases or vapors through the molten metal.

Utilizing scrap iron. T. GOLDSCHMIDT A.-G. Brit. 282,378, Dec. 20, 1926. In utilizing scrap iron as described in Brit. 257,905 (C. A. 21, 3040) the bundled metal is melted by elec. eddy currents, preferably in a high-frequency induction furnace, and the molten iron is worked to produce wrought iron, cast iron or steel by adjustment of the C content and adding any suitable alloying substances desired.

Iron from carbonyl. I. G. FARBERIND. A.-G. Brit. 281,963, June 25, 1927. In producing pure Fe of the kind described in Brit. 262,938 (C. A. 21, 3885), Fe carbonyl in undil. liquid or vaporous condition is allowed to nap gradually into paraffin oil heated to 270°; pyridine, salts such as a mixt. of NaNO₃ and KNO₃, or metallic Pb also may be used.

Pickling iron and steel. JAMES H. GRAVELL and ALFRED DOUTY (Douty to Gravel). U. S. 1,678,776, July 31. A stannous compd. such as SnCl₂ is used in pickling baths contg. acid pickling agents such as H₂SO₄ to control action of the bath. The quantity of stannous compd. is insufficient to cause the scale to dissolve. Sulfite waste liquor also may be added.

Regeneration of steel. HASSENFORDERER & CIE. Fr. 634,370, May 14, 1927. The steel is heated to redness and plunged into a bath contg. mutton fat, tallow, fish-liver oil, colophony, borax, soot, NaCl or saltpeter, calcined bone and leather.

"High speed steel." ARTHUR C. DAVIDSON (to D. Co., Inc., a corp. of N. Y.). U. S. 1,680,937, Aug. 14. Fe, Cr and W are melted, scavenged, Co is added, and, after further scavenging, V is added in less than 50% excess over the desired analysis, Mg or gunpowder also is added, and the metal is cast at a temp. above 1760°.

Steel with high elasticity limit. HERMANN J. SCHIFFLER. Fr. 633,909, May 5, 1927. Steels with a high elasticity limit at low and high temps. are made by adding 0.3 to 1.5% of Al. Other metals or elements may be added to give the steel other properties.

Alloys for bushings. STANISLAW CHOLEWINSKI. Fr. 633,992, May 6, 1927. See Brit. 272,889 (C. A. 22, 1754).

Alloy for coverings of electric meters. S. Z. DE FERRANTI and FERRANTI, LTD. Brit. 281,743, July 12, 1926. In order to prevent tampering with a meter, its cover is formed of a non-magnetic and "undrillable" metal such as Mn steel or an alloy of cast iron 87, Mn 9 and Cu 4%. Various structural features are specified.

Magnetic alloys for telegraphic cables. WILLOUGHBY S. SMITH and HENRY J. GARNETT. Fr. 633,974, May 6, 1927. See Brit. 279,549 (C. A. 22, 2917).

"Heat resistant" alloy. ALFRED L. BORGEHOLD (to General Motors Research Corp.). U. S. 1,680,007, Aug. 7. An alloy which is suitable for valve heads and guides comprises Fe together with C 2.40-2.80, Si 1.75-2.25, Ni 3.75-4.25 and Al 5.75-6.25%.

Alloys of high electric resistance and high initial permeability. W. S. SMITH, H. J. GARNETT and J. A. HOLDEN. Brit. 281,763, Sept. 8, 1926. Ni is alloyed with Fe 10-17, Si 1.5-4 and Cr, V, W and Mo 1-4%. A small proportion of Mn, Mg or Cd

may be used as a deoxidizing agent. Fine wire of the alloys may be annealed for a short time at 880° in N or other inert atm. and then rapidly cooled. Cf. C. A. 22, 2546.

Alloys for high-tension electric conductors. SIEMENS-SCHUCKERTWERKE A.-G. Brit. 281,692, Dec. 2, 1926. Hollow high-tension overhead cables are formed of Al alloyed with Si 0.5-2.0 and Mg 0.4-2.0%. Structural features also are described.

Aluminum alloy. HENRI BENIT. U. S. 1,680,004, Aug. 7. An alloy which may be repeatedly melted without losing its characteristic properties comprises Cu 2, Ni 0.37, W 0.27, Mg 0.45 and "commercial aluminum" 96.91 parts, with 0.5-2.0% impurities.

Aluminum alloys. H. C. HALL and T. F. BRADBURY. Brit. 281,912, March 17, 1927. Al alloys are made contg. Cr 0.05-0.4, Ni 0.2-1.5, Mg 0.1-1.0, Si 0.2-1.5, Fe 0.7-1.5, Cu 2-5% and Sb and Ti (which serve as cleansing agents) up to 0.5% each. The Sb and Ti may be wholly or partly eliminated during the process of making the alloy.

Copper alloys. VICTOR O. HOMERBERG and DEXTER N. SHAW. U. S. 1,680,045, Aug. 7. Alloys such as those contg. Cu 60 and Zn 40 parts are heated above the crit. temp. to obtain substantially a single solid soln., quenched to obtain this solid soln. at room temp. and then reheated and cooled to control the properties of the final product. A chart is given covering the treatment of different alloys. U. S. 1,680,046 relates to the treatment of "muntz metal" which is given a tensile strength of over 75,000 lb per sq. in. and a Brinell hardness of over 200 by reason of very finely divided and uniformly distributed crystals. The metal may be obtained in this condition by heating to above the crit. temp., quenching quickly and reheating to 250°.

Copper alloys. E. MANOS. Brit. 282,095, Dec. 11, 1926. An alloy (for addn., up to 10%, to Cu alloys such as brass or bronze waste) consists of Mn, Al, Mg, Si, Ni and Fe. A final alloy thus formed may contain, e. g., brass waste 90, Mn 7, Al 1, Mg 0.01, Si 0.01, Ni 1.4 and Fe 0.58%. Brit. 282,096 specifies white alloys resistant to oxidation contg. Cu 25-90, Ni 0.5-70, Al 0.05-10, Zn 0.05-50, Fe 0.01-10, Si 0.01-10 and Mg 0.01-5%, with or without addn. of Mn and Cr. An alloy may, e. g., be made contg. Cu 56, Ni 21, Al 2, Zn 20, Fe 0.25, Si 0.5, and Mg 0.25%. Details of making the alloys are given.

Copper alloys. FELIX VISINTAINER. U. S. 1,680,577, Aug. 14. Alloys which are resistant to acids contain Cu 85-89, Al 9-13, Fe 0.25-0.65, Si 0.30-0.70, and Sn 0.07-0.12%.

Hardening copper or copper alloys. O. W. GUSTAFSON. Brit. 281,799, Sept. 21, 1926. The metal at ordinary room temp. is plunged into a bath formed of an inorg. acid and an inorg. salt, also at room temp., e. g., into a bath formed of HNO₃ and NH₄Cl or borax.

Alloying ferrous metal with nickel and other metals. PAUL D. MERICA and THOMAS H. WICKENDEN (to International Nickel Co.). U. S. 1,680,058, Aug. 7. A material for addn. to cast iron or steel comprises Ni and another alloying material such as Cr, Mo or W together with another added substance such as C and Si which serves to lower the m. p.

Iron alloys. A. L. FEILD. Brit. 282,387, Dec. 18, 1926. Stainless or rustless irons contg. about 12-18% Cr and 0.07-0.17% C are made by a 2-stage process in the first stage of which high-C ferro-chrome is incorporated in an Fe bath and C is eliminated by use of Fe ore (or, preferably, roll scale), Cr passing into the slag, and in the second stage of which the greater part of the Cr is reduced from the slag by the addn. of a reducing agent of non-carbonaceous character such as ferro-Si and a basic material such as lime and passes into the metal bath. Ni, Cu, Mo and V may be added.

Lead alloys. HIROSHI YOSHIKAWA. U. S. 1,681,272, Aug. 21. Alloys which are of good strength and resistant to corrosion are formed of Pb alloyed with Bi 0.025-4.0, and with a metal such as Cu or Ni, immiscible with Pb 0.025-5.0%. Cf. C. A. 22, 2351.

Magnesium alloys. JOHN A. GANN (to Dow Chemical Co.) U. S. 1,680,262, Aug. 7. An alloy which may be used for pistons of internal-combustion engines comprises Mg 80-99.5 and Sn 0.5-5-20%. Cf. C. A. 22, 378.

Alloys containing molybdenum. EMIL A. LUCAS (to Molybdenum Corp. of America). U. S. 1,681,123-4, Aug. 14. See Brit. 245,422 (C. A. 21, 221).

Malleable alloys of nickel, copper and iron. T. H. KELLY. Brit. 281,950, May 31, 1927. Alloys contg. Ni 20-40, Cu 20-40 and Fe 40-60 parts are made by melting the metals in an elec. furnace with fluxes which produce a non-oxidizing atm., and with use of Mg, Al, Mn or ferro-Si as a deoxidizer. In some cases, a portion of the Fe may be substituted by Cr.

Alloying and pulverizing nickel. WILLIAM R. VRAZEY (to Dow Chemical Co.). U. S. 1,680,825, Aug. 14. Metallic Ni and Mg are heated together at a temp. which is intermediate the m. p. of the 2 metals, until sufficient Mg is absorbed in the Ni to render it readily pulverizable. The product may be used in making other alloys.

Steel alloy. GEORGE L. NORRIS (to Vanadium Corp. of America). U. S. 1,680,301, Aug. 14. A steel alloy which has a high strength contains Si 0.40–2.0, V 0.05–0.5, Mn 0.20–0.60 and C 0.10–1.0, the remainder being mainly Fe together with the usual impurities of com. steel.

Steel alloys. F. KRUPP A.-G. Brit. 282,015, Dec. 7, 1926. Steel alloys such as Ni-Mn steel (particularly austenitic steels) are stated to have their "yield point" raised by rotating the article, such as a turbo rotor formed from the alloy, at such a speed that the stress in the material exceeds the yield point of the unrestrained metal.

Finely porous metals. I. G. FARBENIND. A.-G. Brit. 282,112, Dec. 13, 1926. One of the constituents of an alloy is removed by a solvent which does not substantially attack the other constituents; e. g., porous Cu is obtained by treating brass with NaOH and subsequently dissolving out the Na zincate with dil. HCl. Alloys of Cu with Sn, Al or Mn may be similarly treated. Alloys of Cu with Ca may be treated with dil. acid. Ni may be obtained from its alloys with Zn and Al, Fe from ferro-Si, and Sn from a Sn-Na alloy by use of water or alc. By eliminating one of 3 metals, alloy mixts. may be obtained such as Pb-Sn, Pb-Sb or Cu-Mn. The products may be used as catalysts.

Porous lead. I. G. FARBENIND A.-G. Fr. 634,032, May 7, 1927. See Brit. 270,763 (C. A. 22, 1549).

Apparatus for cleaning or "branning" tin plates. J. I. RICHARDS, O. G. RICHARDS, J. THOMAS and J. RICHINGS. Brit. 282,194, Nov. 2, 1926.

Apparatus for cleaning and polishing metal plates. J. H. THOMSON, W. E. CLEMENT and D. THOMAS. Brit. 282,532, Nov. 6, 1926.

Apparatus for sandblasting, heating and spray-coating with metal of articles such as pipes or tubes. F. G. COZENS and METALLISATION, LTD. Brit. 282,116, July 17, 1926.

Hollow steel drills, shafts, etc. C. P. MARRISON. Brit. 281,930, April 27, 1927. A tube of stainless steel packed with material such as silica sand is inserted in a hollow steel billet; after rolling, the ends are cut off leaving a tube with a lining resistant to rust.

Electrodes for arc welding. NORMAN B. PILLING and JOHN G. SCHOENER (to International Nickel Co.). U. S. 1,679,002, July 31. Electrodes comprising a normal Ni alloy are provided with a coating contg. Ti approx. 19% and Ca approx. 6% together with Fe 53, Si 17 and Al 5%. U. S. 1,679,003 specifies electrodes comprising a metallic nickelous matrix malleabilized by an alk. earth metal such as Ca with a coating comprising Ti 0.1–10% and Ca 0.1–8% together with Fe, Si and Al. Cf. C. A. 22, 2547.

Welding copper and copper alloys. FREDERICK M. BECKET (to Electrometallurgical Co.). U. S. 1,680,844, Aug. 14. A welding rod of Cu together with Si 1.25–4% is used for welding or brazing Cu or Cu alloys.

Solder. H. A. MEINHARDT. Brit. 282,007, Dec. 10, 1926. A solder bar comprises a tubular sheath of soft solder metal contg. a flux and a soft solder metal of higher m. p. than the sheath.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Chloromethyl benzyl ether and benzyl formal. P. CARRÉ. *Bull. soc. chim.* **43**, 767–8 (1928).—See C. A. 22, 3153. E. H.

Action of acetylene on aryl hydrocarbons in the presence of a mercury catalyst. II. J. A. REILLY and J. A. NIEUWLAND. Univ. of Notre Dame. *J. Am. Chem. Soc.* **30**, 2564–6 (1928); cf. C. A. 18, 2000.—The following ethylidene hydrocarbons were prep. from C_2H_2 and the proper C_6H_5 deriv. in the presence of concd. H_2SO_4 and HgO : $MeCH(C_6H_4CH_2CH_2Me)_2$, b_{12} 192–4°; $MeCH(C_6H_4CHMe)_2$, b_{15} 240–5°; $MeCH(C_6H_4CH_2CH_2CH_2Me)_2$, b_{17} 244–8°; $MeCH(C_6H_4CHMeCH_2Me)_2$, b_{11} 250–2°; $MeCH(C_6H_4CMe)_2$, b_{16} 212–4°, m. 94°; $MeCH(C_6H_4CH_2Et)_2$, b_{19} 234–6°; $MeCH(C_6H_4CHMeCHMe)_2$, b_{18} 225–8°. $C_{10}H_{12}$ gives the *comp. pd.* $MeCH(C_{10}H_{10})_2$, b_{18} 261–3°. These are all viscous, amber-colored liquids. Polynuclear hydrocarbons, such as Ph_3 , Ph_2CH_2 , $(PhCH_2)_3$, Ph_3CH and $C_{10}H_8$ do not react with C_2H_2 . C. J. WEST

The allenic hydrocarbons. MARCEL BOUIS. *Ann. chim.* 9, 402-62(1928); cf. C. A. 22, 213.—B. preps. new drivs. of allene by brominating vinylalkylcarbinols and removing Br_2 with Zn. The vinylalkylcarbinols were prepd. by treating RMgBr with $\text{CH}_2\text{:CHCHO}$ (I), using large vols. of Et_2O , avoiding traces of disacryl, avoiding an excess of I and by decomp. the Grignard with NH_4Cl . iso- PrMgBr with I gives 15% iso- PrCH(OH)CH:CH_2 , b. 125° , d_{20} 0.8368, n_D^{23} 1.4263, M. R. 30.64. iso- $\text{PrCH}_2\text{CH(OH)CH:CH}_2$, b. 118° , d_{20} 0.8288, n_D^{21} 1.4285, M. R. 35.42. The vinyl alcs. are brominated with PBr_3 in the presence of 10% $\text{C}_6\text{H}_5\text{N}$ to prevent the liberation of HBr , and the products distd. *in vacuo*. Rearrangement of the bromide occurs as soon as it is formed; $\text{EtCH(OH)CH:CH}_2 \rightarrow \text{EtCHBrCH:CH}_2 \rightarrow \text{EtCH}\cdot\text{CHCH}_2\text{Br}$, b. 35° , b. $123-4^\circ$, d_{20} 1.2545, n_D^{20} 1.4731, M. R. 33.33. Other allyl bromides similarly prepd. were: $\text{PrCH:CHCH}_2\text{Br}$, b. $42-4^\circ$, d_{16} 1.2119, n_D^{16} 1.4778, M. R. 38.06. iso- $\text{PrCH:CHCH}_2\text{Br}$, b. 46° , d_{24} 1.2208, n_D^{24} 1.4723, M. R. 37.41. $\text{BuCH:CHCH}_2\text{Br}$, b. $62-4^\circ$, d_{17} 1.1682, n_D^{17} 1.4760, M. R. 42.74. iso- $\text{PrCH}_2\text{CH:CHCH}_2\text{Br}$, b. 60° , d_{21} 1.1782, n_D^{21} 1.4750, M. R. 42.30. The bromides were condensed with excess NaOAc in boiling HOAc to give the corresponding esters: $\text{EtCH}\cdot\text{CHCH}_2\text{OAc}$, b. $149-51^\circ$, d_{22} 0.9019, n_D^{22} 1.4219, M. R. 36.06. $\text{PrCH:CHCH}_2\text{OAc}$, b. $171-3^\circ$, d_{18} 0.8976, n_D^{18} 1.4282, M. R. 40.72. iso- $\text{PrCH:CHCH}_2\text{OAc}$, b. 163° , d_{22} 0.8990, n_D^{22} 1.4260, M. R. 40.47. $\text{BuCH}_2\text{CHCH}_2\text{OAc}$, b. $192-4^\circ$, d_{18} 0.8915, n_D^{18} 1.4314, M. R. 45.33. iso- $\text{PrCH}_2\text{CH:CHCH}_2\text{OAc}$, b. $182-4^\circ$, d_{20} 0.8836, n_D^{20} 1.4280, M. R. 45.42. These allyl acetates have been found to be different from the acetates which would have been formed if the bromides did not rearrange. The acetates are hydrolyzed by heating with an excess of aq. NaOH contg. MeOH to aid soln. The alcs. obtained showed no traces of secondary alcs. $\text{EtCH}\cdot\text{CHCH}_2\text{OH}$, b. $138-9^\circ$, d_{23} 0.8444, n_D^{23} 1.4539, M. R. 26.62. $\text{PrCH:CHCH}_2\text{OH}$, b. $158-60^\circ$, d_{16} 0.8490, n_D^{16} 1.4403, M. R. 31.06, forming a naphthylurethan, m. 76° . iso- $\text{PrCH:CHCH}_2\text{OH}$, b. 150 , d_{21} 0.8348, n_D^{21} 1.4357, M. R. 31.30. $\text{BuCH:CHCH}_2\text{OH}$, b. $177-9^\circ$, d_{20} 0.8421, n_D^{20} 1.4410, M. R. 35.75. iso- $\text{PrCH}_2\text{CH:CHCH}_2\text{OH}$, b. 169° , d_{20} 0.8355, n_D^{20} 1.4390, M. R. 35.89. The allyl bromides are converted to the tribromides by the gradual addn. of Br_2 . $\text{EtCHBrCHBrCH}_2\text{Br}$, b. 118 , $122-4^\circ$, d_{19} 2.0714, n_D^{19} 1.5580, M. R. 48.09. $\text{PrCHBrCHBrCH}_2\text{Br}$, b. $117-9^\circ$, d_{16} 1.9429, n_D^{16} 1.5506, M. R. 53.01. iso- $\text{PrCHBrCHBrCH}_2\text{Br}$, b. $131-2^\circ$, m. 35° , d_{26} 1.9139, n_D^{26} 1.5470, M. R. 53.52. $\text{BuCHBrCHBrCH}_2\text{Br}$, b. $142-3^\circ$, d_{17} 1.8112, n_D^{17} 1.5393, M. R. 58.31. iso- $\text{PrCH}_2\text{CHBrCHBrCH}_2\text{Br}$, b. $134-5^\circ$, d_{21} 1.8116, n_D^{21} 1.5380, M. R. 58.19. These tribromides have been converted into the epidibromohydrins by addn. to KOH . EtCHBrCBr:CH_2 , b. $75-6^\circ$, b. 173° (decompn.), d_{19} 1.7442, n_D^{19} 1.5316, M. R. 40.48. PrCHBrCBr:CH_2 , b. $83-5^\circ$, d_{14} 1.6381, n_D^{14} 1.5248, M. R. 45.26. iso- PrCHBrCBr:CH_2 , b. 81° , d_{24} 1.6035, n_D^{24} 1.5180, M. R. 45.73. BuCHBrCBr:CH_2 , b. $108-10^\circ$, d_{18} 1.5595, n_D^{18} 1.5200, M. R. 49.90. iso- $\text{PrCH}_2\text{CHBrCBr:CH}_2$, b. $100-1^\circ$, d_{20} 1.5493, n_D^{20} 1.5155, M. R. 49.87. These dibromides have been added to Zn in boiling alc. to give the corresponding allenic compds. EtCH:C:CH_2 (II), b. 45° , d_{20} 0.6890, n_D^{20} 1.4149, M. R. 24.71. PrCH:C:CH_2 , b. 78° , d_{17} 0.7198, n_D^{17} 1.4298, M. R. 29.42. iso- PrCH:C:CH_2 , b. 70° , d_{22} 0.7061, n_D^{22} 1.4232, M. R. 29.58. BuCH:C:CH_2 (III), b. 106° , d_{21} 0.7374, n_D^{21} 1.4360, M. R. 34.04. iso- $\text{PrCH}_2\text{CH:C:CH}_2$ (IV), b. 96° , d_{19} 0.7225, n_D^{19} 1.4282, M. R. 34.20. α and β are also given. By the methods given above PhCH(OH)CH:CH_2 with PBr_3 gives $\text{PhCH:CHCH}_2\text{Br}$, b. $127-8^\circ$, m. 29° , d_{30} 1.3428, n_D^{30} 1.6157, M. R. 51.25; with NaOAc it gives $\text{PhCH:CHCH}_2\text{OAc}$, b. $139-40^\circ$, d_{22} 1.0520, n_D^{22} 1.5464, M. R. 53.01. Sapon. gives $\text{PhCH:CHCH}_2\text{OH}$, b. $142-5^\circ$, m. 32° , d_{26} 1.0382, n_D^{26} 1.5819, M. R. 43.07. The bromide with Br_2 gives $\text{PhCHBrCHBrCH}_2\text{Br}$, m. 127° . It has been difficult to convert this tribromide to the epidibromohydrin. By treating the allene, with Br_2 in CCl_4 the tetrabromides were formed: $\text{EtCHBrCBr}_2\text{CH}_2\text{Br}$, b. 120° , d_{22} 2.2839, n_D^{22} 1.5916, M. R. 57.46. $\text{PrCHBrCBr}_2\text{CH}_2\text{Br}$, b. 130° , d_{18} 2.1873, n_D^{18} 1.5850, M. R. 61.60. $\text{BuCHBrCBr}_2\text{CH}_2\text{Br}$, b. 140° , d_{20} 2.0675, n_D^{20} 1.5718, M. R. 66.19. II with HBr in HOAc gives a primary fraction which is believed to be a mixt. of $\text{EtCH}_2\text{CBr:CH}_2$ and EtCH:CBrMe ; the second fraction is PrCBr_2Me , b. $62-3^\circ$, d_{18} 1.6452, n_D^{18} 1.5031, M. R. 41.33. II with H_2SO_4 gives PrCOMe . The substituted allenes are added to

NaNH_2 suspended in boiling xylene to give a rearrangement: $\text{EtCH:C:CH}_3 + \text{NaNH}_2 \rightarrow \text{EtCH}_2\text{C:CNa} + \text{NH}_3$. In this manner II, III and IV rearranged to give PrC:CH , $\text{C}_6\text{H}_{11}\text{C:CH}$ and $\text{iso-PrCH}_2\text{CH}_2\text{C:CH}$. D. H. POWERS

The mechanism of action of certain oxidizing agents on alcohols. B. V. TRONOV AND M. A. LUKANIN. *J. Russ. Phys.-Chem. Soc.* 60, 181-91 (1928).—A review of previous papers by T. and co-workers. BASIL C. SOVENKOFF

Constitution of phytol. F. GOTTWALT FISCHER AND KURT LÖWENBERG. *Bayrischen Akad. Wissenschaften München. Ann.* 464, 69-90 (1928).—The phytol used in this investigation, prep'd. according to Willstätter, Mayer and Hüni (*C. A.* 5, 874), b_{10} 170-1°, b_{10} 202.5-4°, d_4^{25} 0.8491, n 1.4623, 1.4601, 1.692 for D, α and γ at 25°. Oxidation with CrO_3 gives the ketone (I), $\text{C}_{18}\text{H}_{36}\text{O}$, b_{10} 173-4°, d_4^{25} 0.8323, n_D^{25} 1.4432; semicarbazone, m. 66-7°; this is the same as obtained by W., M. and H. Oxidation with O_3 also gives I and HOCH_2CHO . It is shown to be 2,6,10-trimethyl-14-pentadecanone by the following synthesis: Catalytic reduction of farnesol gives 2,6,10-trimethyldodecane, b_{11} 119.5-20°, d_4^{25} 0.7682, n_D^{25} 1.4303, and 2,6,10-trimethyl-12-dodecanol, b_{10} 151-2.5°, d_4^{25} 0.8491, n_D^{25} 1.4487; the latter is best obtained by reducing the acetate of farnesol and then saponifying the reduction product. PBr_3 gives 2,6,10-trimethyl-12-bromododecane, b_{10} 150-4°, which, with $\text{AcCHNaCO}_2\text{Et}$, gives I. This suggests for phytol the structure: $\text{Me}_2\text{CH}(\text{CH}_2)_2\text{CHMe}(\text{CH}_2)_2\text{CHMe}(\text{CH}_2)_3\text{CMe:CHCH}_2\text{OH}$. C. J. W.

The hydrogenation of the ether oxides. ALBIN MARTY. *Compt. rend.* 187, 47-9 (1928).—Reducing Pr_2O , $\text{iso-Pr}_2\text{O}$, Bu_2O , Am_2O and $\text{iso-Am}_2\text{O}$ over Ni at 300° with H_2 gives the alc. and hydrocarbon. PhOEt at 180° gives C_6H_{12} and EtOH and at 250°, both EtOH and PhOH are formed. $\text{C}_{10}\text{H}_{18}\text{OMe}$ and $\text{C}_{10}\text{H}_{18}\text{OEt}$ hydrogenated at 280° give MeOH or EtOH and dihydronaphthalene, some tetrahydronaphthalene and tetrahydro- β -naphthol. Guaiacol at 300 mm. and 180° gives $\text{MeOC}_6\text{H}_5\text{OH}$, pyrocatechol, phenol and cyclohexanol. Ph_2O hydrogenated at 300 mm. at 180° gives 5% $(\text{C}_6\text{H}_{11})_2\text{O}$, PhOH , $\text{C}_6\text{H}_{11}\text{OH}$, C_6H_6 and C_6H_{12} . Hydrogenating at higher pressures does not prevent rupture of the mol. D. H. POWERS

Action of disilicon hexachloride on ether. FREDERIC S. KIPPING AND REGINALD A. THOMPSON. Univ. College, Nottingham. *J. Chem. Soc.* 1928, 1989-90.— Si_2Cl_6 , left in contact with about 10 vols. of Et_2O , most of the Et_2O distd., excess of NaOH added and 4-5 cc. of the aq. soln. distd., and the distillate treated with I and alkali, gives CHI_3 ; the recovered Et_2O , again mixed with Si_2Cl_6 , behaved similarly. The quantity of CHI_3 formed is only a few mg. and is not appreciably increased by gently heating the mixt. C. J. WEST

Influence of structure on the solubilities of ethers. I. GEORGE MACDONALD BENNETT AND WM. GEORGE PHILIP. Univ. of Sheffield. *J. Chem. Soc.* 1928, 1930-7.—The mutual solubilities of several ethers in H_2O det'd. in a modified Hill app., designed for 4-5 cc. of each liquid, are reported. The following phys. consts. are given: MeOBu , b. 70°, d_4^0 0.7635, d_4^{20} 0.7441; $\text{MeOCH}_2\text{CHMe}_2$, b. 58°, d_4^0 0.7523, d_4^{20} 0.7311; *Me sec.-Bu ether*, b. 59°, d_4^0 0.7621, d_4^{20} 0.7415; MeOCMe_3 , b. 54°, d_4^0 0.7578; EtOPr , b. 64°, d_4^0 0.7541, d_4^{20} 0.7330; EtOCHMe_2 , b. 53°, d_4^0 0.7440, d_4^{20} 0.7211; MeOPr , b. 37°, d_4^0 0.7494, d_4^{20} 0.7356; MeOCHMe_2 , b. 32°, d_4^0 0.7383, d_4^{20} 0.7237; Pr_2O , b. 91°, d_4^0 0.7360; PrOCHMe_2 , b. 83°, d_4^0 0.7597, d_4^{20} 0.7474; Bu_2O , b. 140°, d_4^0 0.7841; $(\text{CH}_3\text{CHCH}_2)_2\text{O}$, b. 94°, d_4^0 0.8449, d_4^{20} 0.8260. A table is given showing the wt. % of the ether in the aq. phase and the wt. % of H_2O in the ether phase for MeOBu , $\text{MeOCH}_2\text{CHMe}_2$, MeOCHMeEt , MeOCMe_3 , EtOPr , EtOCHMe_2 , diallyl ether and Pr_2O ; for the remainder the wt. % of ether in H_2O is given. Values for the mol. heats of soln. are also given for the 1st 7 ethers. The relative order of the solubilities of the compds. remains the same at all temps. The soly. increases with increased branching of the C chains of the alkyl groups. The considerable soly. of the ethers in H_2O indicates "abnormal" behavior and classifies them as "polar" in the sense suggested by G. N. Lewis. This abnormality, absent in the pure liquid but developed in the presence of H_2O , is evidence of the presence in the latter case of a new mol. species of a polar type. II. Some cyclic ethers. *Ibid* 1937-42.—The following compds. were studied: pentamethylene oxide, α - and β -methyltetramethylene oxides, β,β' -dimethyltrimethylene oxide, b_{178} 78°, d_4^0 (vac.) 0.8550, d_4^{20} (vac.) 0.8348; α,α' -dimethyltrimethylene oxide, b_{178} 71°, d_4^0 (vac.) 0.8490, d_4^{20} (vac.) 0.8279; and α,α' -methyleneethylethylene oxide. Data are given for the mutual soly. of these ethers in H_2O from 0° to 25° and also for the soly. of C_6H_6 in Bu_2O , EtOPr , EtOCHMe_2 , and all but the 2nd and 3rd of the above cyclic ethers. The soly. of the

cyclic ethers in H_2O increases with falling temp. but their relative order is independent of this change. The most striking feature of the results is the large increase of soly. caused by the closure of the ring, and this is also true of the solubilities of H_2O in the ethers. The increase of soly. due to the closure of the ring is also larger the smaller the ring.

C. J. WEST

Effect of structure of organic halides on their rate of reaction with inorganic halides.

II. The effect of the methylthio group. A new vesicant. W. R. KIRNER. Rice Inst. *J. Am. Chem. Soc.* **50**, 2446-55(1928); cf. *C. A.* **18**, 1977.—The method previously developed for detg. the effect of structure of org. halides on their rate of reaction with inorg. halides has been extended to include the influence of the MeS group. This group causes a definite, though weak, alternation in the reactivity of an ω -Cl atom through at least 3 C atoms in a satd. chain. $ClCH_2CO_2Me$ and $MeSNa$ in Et_2O give 38% of *Me methylthioacetate*, b_{11} 53-5°, b_{20} 60-2°; attempts to prep. $MeSCH_2OH$ by hydrolysis of the ester gave a product with 52.5% S. $HOCH_2CH_2Cl$ and $MeSNa$ give 78% of β -hydroxyethyl *Me sulfide*, b_{30} 80.5-1°, d_{20}^{20} 1.0640, n_D^{30} 1.4867; with $MeSK$ the yield is only 33%. With $SOCl_2$ there results the β -Cl deriv., b_{30} 55-6°, b_{20} 44°, d_{20}^{20} 1.1245, n_D^{30} 1.4902; the Grignard reagent from this could not be obtained. γ -Hydroxypropyl *Me sulfide*, b_{30} 105-5.5°, d_{20}^{20} 1.0314, n_D^{30} 1.4832 (76% yield); γ -Cl deriv., b_{29} 71.2°, d_{20}^{20} 1.0863, n_D^{30} 1.4833. The reaction velocities with KI at 50° and 60° are. $BuCl$, 0.0415, 0.1189; $MeSCH_2CH_2Cl$, 0.0629, 0.1666; $MeSCH_2CH_2CH_2Cl$, 0.1044, 0.2373. In an attempt to correlate the structure of ω -haloalkyl sulfides with vesicant action, it was found that only when the halogen atom was in the β -position with respect to the S atom did the resulting compd. possess vesicant action. This appears to be true of β,β -dihaloalkyl sulfides also. No apparent relation exists between vesicant action and the chem. reactivity of the halogen atom, a fact which is not in agreement with the acid theory of skin vesication. $MeSCH_2CH_2Cl$ seems to produce the same general effects as mustard gas and at approx. the same rate.

C. J. WEST

Symmetrical dichlorodimethyl sulfate. V. GRIGNARD, C. TOUSSAINT AND J. CAZIN. *Bull. soc. chim.* **43**, 537-42(1928); cf. *C. A.* **22**, 382.—A study is made of the prepn. of $(ClCH_2O)_2SO_2$ (I) by the action of SO_3 on $(ClCH_2)_2O$ (II) under various conditions. Products are formed which involve the reaction of different ratios of SO_3 and II, depending on the conditions used; in all cases the reactions are not clean. The highest yield (31%) of I, b_{12-13} 103-5°, d_{12} 1.634, n_D^{12} 1.4530, was obtained by heating equimol. quantities of SO_3 and II in an autoclave at 180° for 50 min. FREDERICK C. HAHN

The examination of citronellal and citronella oil. H. I. WATERMAN AND E. B. ELSBACH. Techn. Univ., Delft. *Rec. trav. chim.* **47**, 764-75(1928).—On keeping Java citronella oil in a closed bottle the refraction changes to only a slight extent, viz. n_D from 1.4688 (20.9°) to 1.464 (19.8°) in the course of 7 months; in an open test tube the refraction increases to a larger extent and more with Ceylon citronella oil than with Java citronella oil. The examn. of several com. samples of citronellal showed that the product, purified by means of the bisulfite compd., as well as a sample, the method of whose prepn. was not known, hardly deserve the name citronellal, distn. in a high vacuum not yielding a fraction with the phys. const. of citronellal. However, a sample obtained by fractional distn. of Java citronella oil consisted of nearly pure citronellal and the fractional distn. of this product in a high vacuum yielded several fractions with the same phys. properties, thus showing that the sample was homogeneous. On keeping this sample of citronellal protected from the air the refractive indices and the d. remained unaltered, but when not protected from the air both these phys. const. increased, the changes being due to oxidation. From the oxidation products *citronellic acid* was identified by means of the phys. const. and the Ag salt; the high refractive index of the oxidized citronellal, however, shows that also other oxidation products must be present, the quantity of citronellic acid found by titration not accounting for the high refractive index of the oxidized product. In connection with the researches of Moureu and Dufraisse (*C. A.* **16**, 1439; **17**, 1621) the influence of hydroquinone on the oxidation of citronellal was investigated and it appeared that the addn. of this phenol greatly retards the oxidation, the samples turning yellow after some time. Geraniol has the same influence as hydroquinone and thus the relative stability of Java citronella oil most probably is due to the stabilizing influence of the geraniol. In order to stabilize citronellal, much larger quantities of geraniol are necessary than of hydroquinone.

C. F. VAN DUIN

Reaction of nitrosyl chloride. Addition to III. HEINRICH RHEINBOLDT AND MARTIN DEWALD. Univ. of Bonn. *Ann.* **460**, 305-7(1928); cf. *C. A.* **21**, 1107, 2872.—

Octylaldoxime and NOCl in Et₂O give 1,1-chloronitrosooctane, m. 42° to a deep blue, liquid; the *nonane deriv.*, m. 50–1°; the *decane deriv.*, m. 62°; *dodecylaldoxime*, m. 73°, gives the *dodecane deriv.*, m. 63°. Isovaler- and phenylacetaldoximes give oily products confirming the earlier results. With increase of mol. wt., the stability of the dimeric form of chloronitroso compds. increases, as does the soly. in EtOH. The higher members of the series have only a feeble color in C₆H₆. C. J. WEST

New condensations of ketones with phenols. The phorone di-*m*-cresyl ether. JOSEPH B. NIGDERL. N. Y. Univ. J. Am. Chem. Soc. 50, 2230–5(1928).—Concd. H₂SO₄ (3 mols.), added to an ice-cold mixt. of 3 mols. Me₂CO and 2 mols. *m*-MeC₆H₄OH, keeping the temp. at 0° for 48 hrs. and then heating 1 hr. at 100°, gives 80% of *phorone di-m-cresyl ether* (2,6-dimethyl-2,6-di-[4-hydroxy-2-methyl]phenylheptan-4-one ether) b. 270° (partial decompn.), m. 127°; *di-Br deriv.*, m. 215°; *tetra-NO₂ deriv.*, yellow, m. 243°. Oxidation gives Me₂C(CO₂H)₂ and *m-cresylisovaleric acid*, m. 107° (*di-Br deriv.*, m. 140°; *NO₂ deriv.*, m. 108°). The mechanism of the condensation is discussed. C. J. W.

Diameter of the CH₂ chain in aliphatic acids. CHARLES S. PIGGOT. Carnegie Inst. J. Wash. Acad. Sci. 18, 330–3(1928).—Pentadecylic, palmitic, stearic and behenic acids as well as paraffin wax show on x-ray analysis by the powder method 2 lines of the 1st order which are practically the same distance apart in each case. Conclusion: This measures the short dimension of the acids studied, namely 4.235 Å. U. DAVID DAVIDSON

Constitution of eleostearic acid. F. FRITZ. *Farben-Ztg.* 33, 1224–5(1928).—A brief account of the work of various investigators on the constitution of eleostearic acid as revealed by its oxidation products. The validity of Boeseken and Ravenswaay's formula for the acid (C. A. 20, 44) is considered to be upheld. B. C. A.

Some ill-defined acids of the oleic series. III. "Rapic acid" and other acids of rape and mustard-seed oils. T. P. HILDITCH, T. RILEY AND N. L. VIDYARTHI. Univ. of Liverpool. J. Soc. Chem. Ind. 46, 462–7T(1927); cf. C. A. 21, 2661.—The unsatd. acids contg. 18 C atoms, present in rape, ravisson and mustard-seed oils, are mostly composed of ordinary oleic and linoleic acids, unsatn. commencing between the 9th and 10th C atoms from the CO₂H. In addn. there is present about 1% of isomeric forms of oleic acid. This feature is a characteristic of this group of fatty oils. The isomeric form is liquid at ordinary temp., forms a Pb salt sparingly sol. in cold alc. or Et₂O, and yields a dihydroxystearic acid, m. 117–8°. The lower satd. acid present was palmitic acid, to the extent of about 2%, with not over 0.2% of myristic acid. The erucic acid present was dodecenoic acid. IV. "Cheiranthic acid" of wallflower-seed oil. T. P. HILDITCH AND (MISS) E. E. JONES. *Ibid* 467–9T.—Examn. of English wallflower-seed oil showed the following % compn. for the combined acids: palmitic 3; lignoceric 0.5, oleic 12, linoleic 42, linolenic 4, erucic 38.5. The oil is of the same general type as rape, mustard and other seed-fats of the same general botanical order. The "cheiranthic acid" stated to be present by Matthes and Boltze (C. A. 6, 2187) is a case of mistaken identity. T. S. CARSWELL

A disulfosuccinic acid. H. J. BACKER AND J. M. VAN DER ZANDEN. Univ. Groningen. *Rec. trav. chim.* 47, 776–81(1928).—*meso*-(CHBrCO₂H)₂ was prepd. on exposing to sunlight in a beaker with boiling water a mixt. of 58 g. fumaric acid and 84 g. Br in a sealed Kjeldahl flask; the reaction was finished after 10 min., provided the flask was shaken several times; yield, 87%. Maleic acid can be used also, if it is first converted to fumaric acid, the transformation being carried out according to Wislicenus by means of a small quantity of bromine in sunlight (*Ber.* 29, 1080(1896)). The best way to prep. (:CCO₂H)₂ from *meso*-(CHBrCO₂H)₂ is to run 66 g. KOH in 250 cc. abs. EtOH gradually and with continuous shaking into 69 g. *meso*-(CHBrCO₂H)₂ in 200 cc. abs. EtOH, the mixt. being boiled for an hr.; yield, 92%. A disulfosuccinic acid is obtained on heating in a sealed tube at 100° during an hr. 7.6 g. of the acid K salt of (:CCO₂H)₂, 11.5 g. of potassium pyrosulfite and 50 cc. 1 N KOH; on adding 25 cc. 2 N HCl to the reaction mixt., the tri-K salt of a disulfosuccinic acid crystallizes in a yield of 80%. From this salt the normal K salt was prepd. and this was converted into the normal Ba salt, from which the free acid was obtained in the usual way. The free acid crystallizes with 4 mols. of water, C₄H₄O₁₀S₂·4H₂O, m. 163° (decompn.). The following salts were prepd. and analyzed in the usual way: the *tri-K salt*, C₄H₃O₁₀S₂K₃·H₂O; the *tetra-K salt*, C₄H₂O₁₀S₂K₄·4H₂O; the *tetra-Na salt*, C₄H₂O₁₀S₂Na₄·2H₂O; the *tetra-Tl salt*, C₄H₂O₁₀S₂Tl₄, m. 285°; the *di-Ca salt*, C₄H₂O₁₀S₂Ca₂; the *di-Ba salt*, C₄H₂O₁₀S₂Ba₂·3H₂O; the *tetra-Ag salt*, C₄H₂O₁₀S₂Ag₄; the *di-Pb salt*, C₄H₂O₁₀S₂Pb₂. The structure of the acid, 2,2 or 2,3, has not yet been detd.; the authors, however, think the 2,3-formula the most probable one. In the latter case the acid can be the *dl*-compd., which can be resolved into the optically active components or the inactive *meso*-compound; up to the present moment

the authors have not succeeded in resolving the acid into the optically active components.

C. F. VAN DUIN

Use of solid caustic alkalis for the saponification of esters. E. TASSILLY, A. BELOT and M. DESCOMBES. *Compt. rend.* 186, 1846-8(1928).—The method previously used by T., B. and D. (cf. C. A. 22, 1341), has been applied to many new cases. It consists in treating the ester with pulverized KOH (at least 2 mols. for each ester group). The yields are high.

C. J. WEST

Straight-chain acetylenic glycerols of five carbon atoms. R. LESPICU. *Bull. soc. chim.* 43, 657-62(1928); cf. C. A. 22, 2739.—L. continues the study of the action of (: CMgBr)₂ (I), alkyl halides and alcs. I with CH₂ClCHClCHO in Et₂O for 24 hrs. gives 13% CH : CCH(OH)CHClCH₂Cl (II), b_{12} 90-91°, d_{20} 1.305, n_D^{23} 1.500. Treating II with 10% KOH for 4 hrs. gives 85% CH : CCH.CH(CH₂Cl).O (III), b_{10} 58-60°, b_{100} 152°, d_{20} 1.159, n_D^{23} 1.472.

III sealed with H₂O at 100° for 30 hrs. gives CH : CCH, (OH)CH(OH)CH₂Cl (IV), b_{10} 131-2°, d_{16} 1.289, n_D^{16} 1.504. An isomer of this compd., m. 41-2°. IV with NaOMe in MeOH gives CH : CH(OH)CH(OH)CH₂OMe, b_1 100°, d_{17} 1.12, n_D^{17} 1.473; decompn. occurs at temps. above 100°. IV with H₂O at 90° for 20 hrs. gives CH : CCH(OH)CH(OH)CH₂OH (V), b_1 156-9°, d_{20} 1.217, n_D^{26} 1.489. V with 3 PhNCO gives the triurethan deriv., m. 204-6°. II and III react with NH₃-Cu₂Cl₂ but the remaining compds. do not. They all react with AgNO₃. In the same reaction by which II is prepd. some [CH₂ClCHClCH(OH)C :]₂ is also formed and seps. as crystals. Extg. with C₆H₆ and then with CHCl₃ effects the sepn. of a less sol isomer, m. 139-9.5°. A small quantity of another isomer, m. 96.5-7.5°, is isolated. Mg with CH : CCH₂OMe in Et₂O with ClCH₂CHO (VI) on treatment with HCl gas and K₂CO₃ on vacuum distn. gives 65% CH₂ClCH(OH)C : CCH₂OMe, b_{12} 117.5-8.5°, d_{24} 1.172, n_D^{24} 1.485. VI with BrMgC : CCH₂OMe for several days in Et₂O gives on evapn. of the

Et₂O at 80° and addn. of fresh Et₂O and KOH, 20% $\overline{O}CH_2CHC : CCH_2OMe$ (VII), b_{15} 75-6°, d_{20} 1.024, n_D^{20} 1.4573. VII with H₂O in a sealed tube at 100° for 3 hrs. gives 90% CH₂(OH)CH(OH)C : CCH₂OMe (VIII), b_{12} 155-6°, b_{18} 163°, d_{22} 1.1274, n_D^{22} 1.481. 21 g. of VII with 40 g. MeOH and 7 drops of H₂SO₄ heated 10 hrs. gives MeOCH₂CH(OH)C : CCH₂OMe, b_{10} 115°, d_{23} 1.0508, n_D^{23} 1.4608. VIII with Br₂ in CHCl₃ gives CH₂(OH)CH(OH)CBr : CBrCH₂OMe, m. 51-2°, b_{11} 192°. On treatment with gaseous HBr at 100° isomers are obtained of CH₂(OH)CH(OH)CBr : CBrCH₂OH. D. H. P.

The configuration of the butane-2,3-diols. J. BÖSEKEN and MISS R. COHEN. Techn. Univ., Delft. *Rec. trav. chim.* 47, 839-48(1928).—The configurations of a butane-2,3-diol of biochem. origin and of 2 synthetic products were examd. One of the synthetic products (I) was obtained in the following way: MeCOEt (500 g.), in the same quantity of moist ether, was reduced with 500 g. of Na (cf. Harries, C. A. 5, 3519), the larger part of the ketone being reduced to 2-butanol, the remainder being converted into the pinacol, m. 31°. On heating the 2-butanol with H₃PO₄ (d. 1.7) at 210°, 85% yield 2-butene was obtained, which was converted into the dibromide, which was again converted into the (CHMeOAc)₂ by means of freshly prepd. AgOAc. On sapon. the glycol was obtained with b. 177-80°. The 2,3-butanediol of biochem. origin (II) showed the same b. p. and $\alpha_D + 2.42^\circ$, on fractionation a large fraction being obtained, which solidified and m. 25°, $\alpha_D 0.18^\circ$. Although I appeared to be identical with II, B. and C. did not succeed in crystg. the synthetic compd. A third 2,3-butanediol (III) was prepd. by oxidation of 2-butene with AcO₂H in CHCl₃, a glycol, b. 177-80° being obtained in 54% yield. In order to investigate the configuration of the glycols, II was converted into the disulfate, the strychnine salt of which, (CHMeOSO₂H-

$C_{12}H_{22}N_2O_2 \cdot 2H_2O$, $[\alpha]_D^{20} -32^\circ$, $[M]_D^{20} -305^\circ$, on recrystn. gave several fractions, from which only *inactive* aq. solns. of the glycol disulfate were obtained. By means of brucine also several inactive fractions were obtained together with a small active fraction, thus showing that the biochem. glycol contains a small quantity of the optically active compd. and the same result was obtained by means of the dibrucine salt of the di-3-nitrophthalate, the ester, m. 217° , being obtained from the glycol and 3-nitrophthalic anhydride (m. 163°). The synthetic glycol (I) was also converted into the distrychnine salt of the disulfate, which showed the same rotation as the corresponding salt prepd. from the biochem. glycol and could not be resolved into optical components. The dibrucine salt of the disulfate of the synthetic glycol III on recrystn. gave fractions from which optically active solns. of the disulfate, and of the glycol itself could be prepd. The optically pure compds., however, were not obtained, partial racemization having taken place. The 2,3-butanediol, prepd. by the oxidation of 2-butene by means of AcO_2H thus consists for the greater part of the *dl*-compd., while the glycols I and II consist for the greater part of the *meso*-compd. The glycols I and II hardly have any influence on the cond. of H_3BO_3 , whereas with III a small decrease of the cond. was observed. The oxidation of olefins with AcO_2H acid always giving the *trans*-diol, the butene, which is formed by the action of H_3PO_4 on 2-butanediol, is the *cis*-compd. Probably at the high temp. of this reaction (210°) the stable compd. is formed and thus B. and C. conclude that the Me groups attract one another. C. F. VAN DUIN

Action of nitrous acid on amino compounds. II. Aliphatic amino acids. THOMAS W. J. TAYLOR. Dyson Perrins Lab., Oxford. *J. Chem. Soc.* 1928, 1897-906; cf. C. A. 22, 3131.—The velocity of reaction of HNO_2 with $H_2NCH_2CO_2H$, $MeCH(NH_2)CO_2H$ and $H_2NCH_2CH_2CO_2H$ has been measured at 25° in dil. aq. soln. The reaction is approx. of the 3rd order and is retarded by the presence of neutral salts or of mineral acids. The principal reacting species are undissociated HNO_2 and the NH_2 acid in its "Zwitterion" form $NH_3^+ \cdot R \cdot COO^-$. The implications of this result are discussed. The following values are reported for k (min. $^{-1}$) and K_s : $H_2NCH_2CO_2H$, 46, 4.7×10^{-3} ; $MeCH(NH_2)CO_2H$, 32, 2.45×10^{-3} ; $H_2NCH_2CH_2CO_2H$, 45, 2.49×10^{-4} . C. J. W.

Malononitrile and malononitrile condensations. I. RUDOLF SCHENCK, H. FINKEN, P. MICHAELIS AND FR. PLEUGER. Univ. of Münster. *Ann.* 462, 158-73 (1928).— $CH_2(CN)_2$ (6.6 g.) and 15 g. $(CO_2Et)_2$ in 100 cc. EtOH, condensed with 4 g. K in 50 cc. EtOH, give 76% of the K salt, m. 205° , of *Et dicyanohydroxyacrylate*, $(NC)_2C \cdot C(OK) \cdot CO_2Et$; the K salt of the Me ester is similarly prepd. (89% yield). There were also prepd. the Na salt, crystg. with $2H_2O$, the diethylamine salt and the Ag salt of the Et ester and the Ag salt of the Me ester. From 2 mols. of $CH_2(CN)_2$, there results the *di-K* salt of *aci-oxalylidimalononitrile*, $[C(OK):C(CN)_2]_2$, orange- to brick-red, sol. in H_2O with a red color; $AgNO_3$ ppts. the Ag salt; H_2SO_4 gives a ppt. of the free tetranitrile, which could not be filtered. $CH_2(CN)_2$ and HCO_2Et give 81% of the K salt, m. 268° , of hydroxymethylenemalononitrile, $(NC)_2C:CHOK$; the Ag salt is sol. in a large quantity of hot H_2O and NH_4OH and on long boiling ppts. Ag; warming with alkali gives NH_3 . $NCCO_2Et$ gives the K salt of *cyanohydroxymethylenemalononitrile*, which evolves HCN on crystg. from 90% EtOH. The Ag salt is easily sol. in NH_4OH . The Ag salt with the proper alkyl iodide gives the following derivs.: Me and Et dicyanomethoxyacrylate, and Me and Et dicyanoethoxyacrylate. Sapon. of these esters gives the free acids. Et dicyanohydroxyacrylate yields a phenylhydrazine salt, m. 100° , and an NH_4 salt, m. 176° . The Me ester gives a phenylhydrazine salt, m. 104° , and an NH_4 salt, m. 209° . The esters with 5% EtOH- NH_3 give the amides of dicyanoethoxy- and methoxyacrylic acids, m. 141° and 140° ; concd. aq. NH_4OH gives the NH_4 salt of dicyanohydroxyacrylic amide. C. J. WEST

Heterogeneous catalysis and adsorption. II. C. F. VAN DUIN. *Rec. trav. chim.* 47, 715-36 (1928); cf. C. A. 15, 3783; 17, 1745.—Previously Kruyt and van D. have shown that the addn. of C to a reacting system in general decreases the velocity of a reaction, even in cases where undoubtedly all the reacting compds. are present in the surface layer of the C in increased concns. An explanation of these results was given based on the theory of Langmuir and Harkins concerning the special conditions of mols. which are situated in the surface layer, the hypotheses being put forward: (a) that adsorbed mols. have lost more or less their mobility and consequently are in a less favorable condition to meet other mols. and to take part in a reaction; (b) that adsorption can cause positive catalysis only in the case when the orientation of the adsorbed mols. is such that the reacting groups are turned away from the absorbent and towards the surrounding liquid. The orientation must be such a favorable one that the primary decrease of the velocity of the reaction, caused by the adsorption itself, is overcome. Exptl. evidence in favor of these assumptions was given by means

of the reaction of inorg. iodides with the acid and normal Na salts of p -HO₂SC₆H₄-CHBr-CHBrCO₂H and with BrCH₂CHBrCO₂H, in accordance with the theory the reaction being *retarded* in the former case and *accelerated* in the latter case by the addn. of C. Previously the reaction with BrCH₂CHBrCO₂H had not been carried out quite satisfactorily, *viz.*, in the presence of air, and therefore it has now been repeated with the acid itself as well as with its Na salt, an acceleration being found again in both cases by the addn. of C. The sapon. of m -MeO₂SC₆H₄CO₂Me (K_{18} = 4.32), of o -MeO₂SC₆H₄CO₂Me (K_{18} = 0.00750), of iso-BuCO₂Me (K_{18} = 1.21), of mono-acetin (K_{18} = 11.55), of mono-Me succinate (K_{18} = 2.32), of mono-Me *d*-tartrate (K_{18} = 13.69), of di-Me *meso*-tartrate and the inversion of sucrose with 0.239 *N* HCl (K_{25} = 0.00191) were investigated and it was shown that the addn. of C *retards* the reaction in all these cases. Even in the most favorable case, the sapon. of di-Me *meso*-tartrate, the acceleration of the reaction, due to the undoubtedly favorable orientation of the adsorbed mols., is insufficient to overcome the decrease of the velocity of the reaction in consequence of the less favorable condition of adsorbed mols. to take part in a reaction. The monomol. transformation of *dl*-(CHBrCO₂H)₂ into bromofumaric acid and HBr (K_{25} = 0.000097) was shown to be *retarded* by the addn. of C. This result strongly supports the 1st hypothesis, put forward by K. and van D., *viz.*, that adsorbed mols. are in a less favorable condition to meet other mols. and to take part in a reaction, with truly monomol. reactions any effect due to adsorption is not to be expected unless the condition of the mols. is changed by the adsorption itself. The reaction between *dl*- and *meso*-(CHBrCO₂H)₂ and KI (formation of maleic or fumaric acid), was shown to be *greatly accelerated* by the addn. of C, the acceleration being much greater than with BrCH₂CHBrCO₂H and its Na salt. This result strongly supports the 2nd hypothesis of K. and van D., mentioned above. With *dl*-BrCH₂CHBrCO₂H we are dealing with the interesting case where the addn. of C *retards* the monomol. and *accelerates* the trimol. transformation of the same compd. Expts. have also been carried out on the sapon. of mono-Me *d*-tartrate and di-Me *meso*-tartrate with an alk. SnO suspension, in the former case a *decrease* of the velocity being found and in the latter case the same velocity as in the absence of the colloidal SnO. This result can be explained in 1 way only, *viz.*, that in the case of mono-Me *d*-tartrate the orientation of the adsorbed mols. is less favorable than with di-Me *meso*-tartrate. Thus in the former case the retarding influence, due to the adsorption, preponderates, while in the latter case this retarding influence is just compensated by the accelerating influence in consequence of the favorable orientation of the adsorbed mols. The prepn. of iso-BuCO₂Me, *b₇₆* 116.4–6.8°, of monomethyl succinate, *m. p.* 58–9°, from succinic anhydride and MeOH, of mono-Me *d* tartrate, 2H₂O, *m.* 76–7°, by esterification of *d*-tartaric acid with MeOH and of di-Me *meso*-tartrate, *m.* 114°, by esterification of *meso*-tartaric acid with MeOH and by interaction of the normal Ag salt with MeI, are described. C. F. VAN DUIN

Influence of constitution on the stability of racemates. ALEXANDER FINDLAY AND ALAN N. CAMPBELL. Univ. of Aberdeen. *J. Chem. Soc.* 1928, 1768–75.—The *f. p.* and *soly.* (in 93.8% EtOH by wt.) curves of active and *dl*-forms of tartaric acid, its Me ester, the Me esters of the di-Ac, di-EtCO and di-Bz derivs. and of the Et esters of di-Ac and di-Bz derivs. have been detd. The introduction of an acyl group into the Me or Et ester of the acid lowers the *m. p.* of the *dl*-form relatively to that of the active form and reduces the range of stability of the *dl*-form. In this respect the Ac group is much more effective than the EtCO or Bz group. *d*- and *l*-Tartaric acids form a eutectic at 161.6° and 94.3% of the *d*-acid; Me diacetyltartrates at 79° and 53.6% of the *d*-ester; Et diacetyltartrates at 42° and 55.7% of the *d*-ester; Me dipropionyltartrates at 24° with 75% of the *d*-ester; Me dibenzoyltartrates at 130.4° and 94.5% of the *d*-ester. *Et dl*-dibenzoyltartrate, *m.* 105°; *Me ester*, *m.* 144.5°. The transition point of Me diacetylracemate lies at about 23°; transition points are discussed. C. J. W.

Rotatory dispersion of derivatives of tartaric acid. III. Diacetyltartaric acid and its esters. PERCY C. AUSTIN. Westminster Training College, London. *J. Chem. Soc.* 1928, 1825–31; cf. *C. A.* 20, 50.—From earlier work it was concluded that diacetyltartaric acid afforded the 1st instance of simple dispersion in the tartaric acid series which was independent of ring formation. Because the conclusion was regarded with some suspicion the Me, Et, Pr, iso-Pr, Bu and iso-Bu esters were studied. The rotatory dispersion of the acid and the esters are reported for some 20 wave lengths from 6708 to 3720; the Pr, Bu and iso-Bu esters were used as such, the others in Et₂O or Me₂CO. The Bu, iso-Bu and Pr esters gave max. in the visible region and the Et ester in Me₂CO showed a reversal of sign in the red; the rotatory dispersion of the Me ester in Me₂CO was so nearly simple in the visible region that there was at first some uncertainty as to whether the dispersion was simple or complex. The readings in

Me_2CO could not be extended beyond 3720 Å. U. The complexity of the free acid was established by using dry Et_2O . The results show that the dispersion of the other esters is anomalous, but that of the Me ester and of the acid is complex but normal; the dispersion consts. λ_1^2 and λ_2^2 are 0.0507 and 0.0691, resp., for the acid and its Me ester, and 0.0457 and 0.0507 for the other esters. IV. Propyl and butyl tartrates. *Ibid* 1831-4.—Results are reported for the rotatory dispersions of Pr, iso-Pr, Bu and iso-Bu tartrates at 20° for some 20 wave lengths. In every case the rotatory dispersion is both complex and anomalous, but although the same dispersion consts. are used throughout the series, no simple relation appears to exist between the rotation consts. C. J. W.

Nitroaminoguanidine. ROSS PHILLIPS AND JOHN F. WILLIAMS. Univ. of Buffalo. *J. Am. Chem. Soc.* 50, 2465-70 (1928).— $(\text{NH}_2)_2\text{H}_2\text{SO}_4$ (32.53 g.) in 200 cc. H_2O and 500 cc. N NH_4OH , treated with 26 g. $\text{H}_2\text{N}(\text{HN}:\text{C})\text{NHNO}_2$ give 13.1 g. nitroaminoguanidine (I); no indication of $\text{HN}:\text{C}:\text{N}(\text{NH}_2)_2$ was obtained. A method of analysis is given. I is sol. in H_2O to the extent of 0.34% at 20° and 3.0% at 70°; I m., accompanied by explosion, about 190°; it reduces KMnO_4 , $\text{K}_2\text{Cr}_2\text{O}_7$, Nessler reagent and $\text{NH}_4\text{OH}-\text{AgNO}_3$, also Fehling with the formation of an explosive Cu compd. I in dil. alkali, treated with a trace of Ni salt, gives an intense deep blue color, which lasts for 15-20 min. This test can be made to detect as little as 0.0002 mg. of Ni. Co and a no. of other metals failed to give this test. Tests for I are described. Cryst. compds. were prepd. from aldehydes and ketones. With NiSO_4 and NH_4OH I gives the compd. $\text{NiO}[\text{HN}:\text{C}(\text{NHNO}_2)-\text{NHNH}_2]_2$, insol. in H_2O (hot or cold) but gives a deep blue alk. soln.; H_2SO_4 decomps. it with the formation of a toxic gas. It explodes when placed in a flame but may be heated to 220° without detonation. I may serve as a reagent for Ni detn. Reduction of I with Zn and AcOH gives diamingoguanidine. C. J. WEST

Acetylmonoses. IV. Two isomeric triacetylmethyllyxosides. P. A. LEVENE AND M. L. WOLFROM. Rockefeller Inst. *J. Biol. Chem.* 78, 525-33 (1928); cf. C. A. 21, 1969.— α -methyl-*d*-lyxoside triacetate, prepd. from α -methyl-*d*-lyxoside had the following properties: crystallizes in prismatic needles, sol. in Et_2O , CHCl_3 , MeOH, less sol. in EtOH and slightly sol. in petroleum ether and H_2O , m. 96°, $[\alpha]_D^{20}$ 30.4° in CHCl_3 . From α -*d*-lyxoside tetraacetate, the γ -methyl-*d*-lyxoside triacetate was prepd. which m. 90°, $[\alpha]_D^{20}$ -103.5° in CHCl_3 . Both isomers were also prepd. from the lyxose tetraacetate after bromination. The behavior of the 2 isomers to MeOH contg. 0.1% HCl varied, the γ -form giving a rapid fall in optical rotation (-98.3° to -16° in 10 min.) while the α -form was very resistant to such treatment (30.0° to 29.0° in 2 hrs.). The γ -compd. was found on analysis to be almost completely deacetylated at the end of 20 min. H. J. DEUEL, JR.

Influence of substituents in the benzene nucleus upon the reaction of silver salts of *o*-hydroxy carboxylic acids with acetobromoglucose. KARL JOSEPHSON. Univ. Stockholm. *Ann.* 464, 227-36 (1928).—The Ag salt of *m*-cresotinic acid and acetobromoglucose give a mixt. of tetraacetylglucose *m*-cresotinate, m. 151° (all m. p. cor.), $[\alpha]_D^{20}$ -46.5° (CHCl_3), and tetraacetylglucosido-*m*-cresotinic acid, m. 145°, $[\alpha]_D^{20}$ -28.3°. β -Glucosido-*m*-cresotinic acid, m. 142°, $[\alpha]_D^{20}$ -56.2°. With the following only the ester was obtained. Tetraacetylglucose 3-nitrosalicylate, m. 140°, $[\alpha]_D^{20}$ -42.8° (2-Ac deriv., m. 145°, $[\alpha]_D^{20}$ -73.8°); the 5- NO_2 isomer, m. 174°, $[\alpha]_D^{20}$ -47.2° (2-Ac deriv., m. 166°, $[\alpha]_D^{20}$ -44.3°). If we assume with Karrer that glucoside formation depends upon the complex nature of the corresponding Ag salt, then we must conclude that a Me in the 3-position to the CO_2H group or a NO_2 group in the 3- or 5-position to the CO_2H group hinders the inner complex formation of the Ag salt. C. J. WEST

α -Glucoheptulitol. GABRIEL BERTRAND AND GEORGES NITZBERG. *Compt. rend.* 186, 1773-6 (1928); cf. C. A. 22, 2740.— α -Glucoheptulitol is found to have the following properties: m. 144°, α_D^{20} -2° 24'; acetate, m. 116-7°. The problem of its structure is discussed. REYNOLD C. FUSON

Oxidation of glucose in alkaline solution with the production of carbon monoxide. Details of the reaction. Behavior of different sugars. MAURICE NICLOUX. *Compt. rend. soc. biol.* 99, 226-8 (1928); cf. C. A. 22, 2742.—A 0.5% soln. of glucose in a medium with an alk. 0.1 *N*, and 50 cc. of O was agitated at 5 temps. ranging from 81° to 92°. The max. O consumed and CO formed was at 84°. Slightly more CO_2 was formed at 88° than at 84°, but less CO_2 at 92°. The ratio CO/CO_2 changed from 1/3.08 at 81° to 1/43 at 92°. The % of O consumed on the basis of O supplied, increased from 19.6 at 81° to 32.1 at 92°. In the oxidation of glucose KOH, NaOH and LiOH have the same action. $\text{Ba}(\text{OH})_2$ and $\text{Ca}(\text{OH})_2$ are slightly weaker. When Na_2CO_3 is substituted for NaOH about 0.5 as much CO is produced. NaHCO_3 at 40° is without action.

Levulose, lactose, galactose and maltose acted like glucose in the production of CO. Sucrose in alk. soln. was not attacked by O under the conditions of these expts. so long as it was not inverted. L. W. RIGGS

Mechanism of tautomeric interchange and the effect of structure on mobility and equilibrium. III. The function of alkaline and acid catalysts in the mutarotation of some derivatives of tetramethylglucose. JOHN WM. BAKER. Univ. of Leeds. *J. Chem. Soc.* 1928, 1979-87; cf. *C. A.* 22, 3395.—Previous work showed that catalysts which facilitate the prototropic change involved in the mutarotation of sugars may be of two kinds—those which attack the ionizing proton directly and those which facilitate its liberation indirectly. Acids, which fall within the 2nd category of catalysts, function by inducing a positive charge on the N atom, which in turn facilitates the liberation of the attached proton. The action of acids and alkalies is now studied, by using derivs. of tetramethylglucose. With acid catalysts it is again found that, as the group R is varied, the velocity of mutarotation runs parallel with the strength as bases of the compds. RNH_2 , viz., $p\text{-MeOC}_6\text{H}_4 > p\text{-MeC}_6\text{H}_4 > \text{Ph} > p\text{-ClC}_6\text{H}_4 > p\text{-BrC}_6\text{H}_4$. The results obtained for alk. catalysts are more complicated and their interpretation is much less clearly defined than in the case of acid catalysts. It seems probable that at least 2 different types of mechanism may function, 1 of which is most powerful with the deriv. of the weakest base, the other reaching its max. with the deriv. of the strongest base. The superimposition of these 2 mechanisms may therefore lead to the existence of a min. value for the velocity of mutarotation at some intermediate point in the series. The following anilides of tetramethylglucose were prepd.: *p*-bromoanilide, m. 154°; *p*-chloroanilide, m. 141°; *p*-toluide, m. 151°; *p*-aniside, m. 110°. With 0.9 N AcOH in AcORt, the following values for the unimol. velocity coeff. (hr.^{-1}) were obtained: BrC_6H_4 , 0.39; ClC_6H_4 , 0.46; Ph, 1.30; MeC_6H_4 , 4.12; MeOC_6H_4 , 12.0. With 0.0006 N EtONa, the following values were found: ClC_6H_4 , 1.33; BrC_6H_4 , 1.24; Ph, 1.13; MeC_6H_4 , 1.21; MeOC_6H_4 , 2.41; with 0.001 N EtONa: ClC_6H_4 , 11.4; BrC_6H_4 , 9.1; Ph, 7.7; MeC_6H_4 , 6.1 (min); MeOC_6H_4 , 14.7. C. J. WEST

Mechanism of carbohydrate oxidation. X. The action of potassium hydroxide on mannose. A comparison with that of glucose and fructose. WM. LLOYD EVANS AND DAVID C. O'DONNELL. Ohio State Univ. *J. Am. Chem. Soc.* 50, 2543-56 (1928); cf. *C. A.* 22, 3140.—The action of aq. KOH of various concns. on mannose was studied at 25°, 50° and 75° in order to ascertain whether this hexose, like fructose and glucose, reacts in accordance with the suggestion that the alk. solns. of these well-known carbohydrates contain an equil. system which can be disturbed by changes in the exptl. conditions, temp. and alkali normality. The reaction mixts. were examd. quant. for AcCHO, lactic, acetic and formic acids. Changes in temp. and alkali concn. produced changes in the yields of these compds. which were of the same general character as those obtained under exactly the same conditions from fructose and glucose. The interdependence of the reactions producing AcCHO, lactic, acetic and formic acids in alk. solns. of glyceric aldehyde and $\text{CO}(\text{CH}_2\text{OH})_2$ is also found to exist between the reactions producing these same products when they are obtained from alk. solns. of mannose, glucose and fructose under the same exptl. conditions. This fact is regarded as evidence for the assumption that the formation of glyceric aldehyde, a fission product of 3,4-hexose enediols, is an intermediate step in the production of these compds. from the hexose sugars. It is predicted that this interdependence will be found to exist in the products of the interaction of aq. solns. of KOH and all of those hexose sugars which are not available for lab. experimentation at the present time. At the lower temps. and the lower alkali normalities, the quantities of reaction products obtained from mannose, glucose and fructose are not the same. This is understood on the ground that the equil. formed in each individual case with the hexose and alkali are not quant. identical. At 75° the quantity of lactic, acetic and formic acids obtained from mannose, glucose and fructose are practically the same in each case. These facts seem to support the view that the equil. systems in the alk. solns. of these hexose sugars are identical at this temp. C. J. WEST

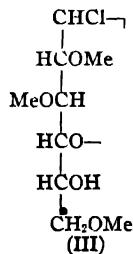

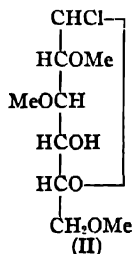

The α - and β -forms of diacetone-methylmannoside. P. A. LEVENE AND G. M. MEYER. Rockefeller Inst. for Med. Research. *J. Biol. Chem.* 78, 363-7 (1928).—Three diacetone-methylmannosides were investigated: the α -d-rotatory form (I) made by acetonization of normal α -methyl-d-mannoside; another α -d-rotatory form (II) made by methylation of diacetone-mannose by Ag_2O and MeI by Purdie's method; and the β -l-rotatory form (III) made by methylation of diacetone-mannose by Freudenberg's method with metallic Na and MeI. I and II differed in numerical values of their d-rotation. By purification it was possible to raise both these rotation values but the value of II was raised considerably more than I. It was found that all 3 preps. hydro-

lyze at the same rate, being completely hydrolyzed in 90 min. It is assumed that they all possess the <1,4> lactal structure. Based on this assumption it is concluded that acetynylation changes the <1,5> lactal structure of methylmannoside into the <1,4> lactal structure.

Chemical structure of α -lignin. PETER KLASON. *Svensk Kem. Tids.* **40**, 3-8 (1928).—Substances in sulfite-liquor wastes pptd. by $C_{10}H_7NH_2 \cdot HCl$ are designated α -lignosulfonic acids. Previous articles have shown their relation to cinnamic aldehyde derivs. To establish more definitely this relation coniferylhydrosulfonic acid was synthesized and pptd. with $C_{10}H_7NH_2 \cdot HCl$, starting from vanillin (Pauly, *C. A.* **17**, 2418). The sulfite-waste ppt. and synthetic product are strikingly alike. They melt at high temps. to a pitch which hardens to a friable resin with cold water. They continuously lose H_2O on prolonged drying. Dil. $Ba(OH)_2$ in the cold yields the neutral Ba salts but on warming and with excess $Ba(OH)_2$ they give insol. basic salts difficultly decompd. by H_2SO_4 . Coniferylaldehyde is to lignin what glucose is to cellulose. (See also Klason, *C. A.* **19**, 1854)

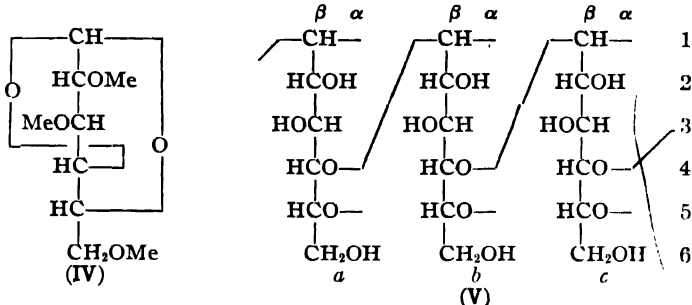

A. R. ROSE

Lignin and cellulose. V. Methylcellulose. KARL FREUDENBERG AND EMIL BRAUN. Univ. of Heidelberg. *Ann.* **460**, 288-304 (1928); cf. *C. A.* **21**, 1818.—It was shown recently by Urban (*C. A.* **20**, 3080) that the methylation of cellulose at 20° gives a tri-Me deriv. (I) essentially different from those obtained by previous investigators. It dissolves to a clear and very viscous soln. in $CHCl_3$, C_2H_5Cl and $AcOH$, while the specimens of Denham and of Irvine and Hirst did not. Further, it differs from the product obtained by Hess in being quite insol. in H_2O and not crystg. from other solvents. It is formed in 93% yield from unbleached cotton, while previous preps. were obtained in only about 75% yields. With $MeOH \cdot HCl$ it gives 91% of 2,3,6-trimethylglucoside and 9% of dimethylmethylglucoside, corresponding with the original MeO content (44.4%) of the sample used. No trace of tetramethylglucose was found. This establishes the structural identity and stereochem. similarity of all the glucose units present in the cellulose mol. When I, for the prepn. of which additional details are given, is treated with HCl in Et_2O (sealed tube at 35°), it yields 1-chloro-2,3,6-trimethylglucose (II or III), analyzed as the pyridinium salt, decomps. 180° , $[\alpha]_D^{16}$ 26.6° (H_2O). Powd. Na converts the Cl deriv. in cold Et_2O into 2,3,6-trimethylglucose anhydride (IV), a mobile oil, $b_{0.1}$ $83-5^\circ$, $[\alpha]_D^{16}$ -10.1° (in H_2O , 16.5° , in $CHCl_3$, -14.6°),

d_{15} 1.1593, n_D^{14} 1.4656; it contains no HO groups, is stable to Fehling soln., $KMnO_4$ and $Br \cdot H_2O$ and with 8% HCl gives 2,3,6-trimethylglucose. The complete dissimilarity of trimethylcellulose and the above anhydride (the latter gives a filterable mobile soln. in $CHCl_3$ and has a normal mol. wt. in C_6H_6 ; a 2% $CHCl_3$ soln. of the former is too viscous to be poured and the mol. wt. is immeasurably large) shows that I is not a trimethylglucose anhydride and therefore that cellulose is not a unimol. glucose anhydride as suggested by Hess. The results of Micheel and Hess (*C. A.* **21**, 173) for the prepn. of 2 forms of IV could not be confirmed; the IV had a considerable b. p. range and 2 fractions obtained from it had $[\alpha]_D$ 23° and 50° , resp., the former giving rise to a trimethylglucose with $[\alpha]_D$ only 63.5° . 1-Dimethylamino-2,3,6-trimethylglucose, by heating the glucose with $MeOH \cdot Me_2NH$ 2 days at 100° , $b_{0.1}$ 109° , $[\alpha]_D^{16}$ 7.2° ($MeOH$), 18.6° (H_2O); MeI gives a quaternary ammonium iodide, $[\alpha]_D^{16}$ -41.2° (H_2O); the chloride has $[\alpha]_D^{16}$ -9.4° (H_2O) (the product according to M. and H. had $[\alpha]_D^{16}$ -8.7°). A consideration of the facts shows that there can be no reversible interconversion of I and IV; moreover, cellobiose must be a degradation product of cellulose, not a product of resynthesis from glucose. Ordinary covalency linkings unite the glucose units in cellulose, probably as in V. If cellulose contains the linkings $a_1\alpha-a_4$, $b_1\alpha-b_6$ and $c_1\alpha-c_6$, degradation would

lead to reducing and tetramethylglucose fragments. With linkings $a_1\alpha-b_1$, $b_1\alpha-c_1$ and $c_1\alpha-d_1$, etc., the same might apply but is not necessitated. More probable linkings are either (with a_β attached to OH and c_4 to H) $a_1\alpha-a_1$, $b_1\alpha-b_1$, and $c_1\alpha-c_1$ or $a_1\beta-a_1$,

$a_1\alpha-a_1$, $b_1\alpha-b_1$ and $c_1\alpha-c_1$. 2,3,6-Trimethylglucose and PCl_5 in Et_2O give the compd. $(\text{C}_5\text{H}_{10}\text{O}_6)_2\text{PCl}_3$, decomps. 160° . Trimethylmethylglucoside and PCl_5 in CHCl_3 give a sirupy chlorohydrin (Cl in position 4?), $b_{0.1}$ 88–95°, $[\alpha]_D^{20}$ 1.64° (CHCl_3); with HCl it yields 2,3,6-trimethylglucose-4(?)-chlorohydrin, $b_{0.1}$ 140–50°, $[\alpha]_D^{20}$ 27.5° (CHCl_3); with Na this, in turn, yields a 2,3,6-trimethylhexose anhydride, $b_{0.1}$ 84°, $[\alpha]_D^{20}$ 106.8° (in H_2O , 112.8°). Hydrolysis of the latter with HCl gives a trimethylhexose, $[\alpha]_D$ 95.2° (H_2O), methylation gives a methylhexoside, $[\alpha]_D$ 33°, hydrolyzed to a tetramethylhexose, $[\alpha]_D$ 55°, not identical with tetramethylgalactose. The hexose anhydride, however, is not a deriv. of glucose. C. J. WEST

Possibility of ring-chain valency tautomerism and of a type of mobile-hydrogen tautomerism analogous to the Wagner-Meerwein rearrangement. III. Orientation of some cyclic derivatives of phorone. CHRISTOPHER K. INGOLD AND CHARLES WM. SHOPPEE. Univ. of Leeds. *J. Chem. Soc.* 1928, 1868–73; cf. *C. A.* 22, 3396.—The compd. $\text{AcOC}:\text{CBr}:\text{CMe}_2:\text{CMe}_2:\text{CO}$ and the corresponding $\text{AcOC}:\text{CH}:\text{CMe}_2:\text{CMe}_2:\text{CO}$

have been orientated by the prepn. from the dihydro deriv. of 5-acetoxy-2,2,3,3-tetramethylcyclopentanone oxime, m. 93° , whose HCl salt m. $136-7^\circ$ (evolution of HCl); reduction gives 2,2,3,3-tetramethylcyclopentylamine (I); this was also obtained by reduction of $\text{OC}:\text{CH}_2:\text{CMe}_2:\text{CMe}_2:\text{C}:\text{NOH}$, first with Na-Hg and AcOH and then with HI

and red P. Reduction of $\text{BzOC}:\text{CH}:\text{CMe}_2:\text{CMe}_2:\text{CO}$ (II) with Pd-BaSO₄ and H gives $\text{BzOCH}:\text{CH}_2:\text{CMe}_2:\text{CMe}_2:\text{CO}$ (III), whose oxime is also reduced to I. $p\text{-BrC}_6\text{H}_4\text{CH}_2\text{OC}:\text{CH}:\text{CMe}_2:\text{CMe}_2:\text{CO}$ is only slightly reduced by H and Pd-BaSO₄;

however, the acetoxime is reduced by Na-Hg and then by HI to I. BzOPh , heated with $\text{NH}_2\text{OH}:\text{HCl}$ and AcONa in abs. EtOH, gives PhOH and BzOH equiv. to about 20% hydrolysis; without the $\text{NH}_2\text{OH}:\text{HCl}$ no trace of BzOH was found. III gives an oily oxime and BzOH. 5-Methoxy-2,2,3,3-tetramethyl- Δ^4 -cyclopentenone with $\text{NH}_2\text{OH}:\text{HCl}$ gives the dioxime of 3,3,4,4-tetramethylcyclopentane-1,2-dione. Oxidation of II with $\text{K}_3\text{Fe}(\text{CN})_6$ gives $\text{HO}_2\text{CCOCMe}_2:\text{CMe}_2:\text{CO}_2\text{H}$, while H_2O_2 gives $\text{HO}_2\text{CCH}_2:\text{CMe}_2:\text{CMe}_2:\text{CO}_2\text{H}$. Oxidation of the corresponding 5-Ac deriv. with $\text{K}_3\text{Fe}(\text{CN})_6$ gives a poor yield of $\text{HO}_2\text{CCMe}_2:\text{CMe}_2:\text{CO}_2\text{H}$. $\text{HOC}:\text{CH}:\text{CMe}_2:\text{CMe}_2:\text{CO}$ and $\text{K}_3\text{Fe}(\text{CN})_6$ give a

good yield of the same acid.

C. J. WEST

cis-trans-Isomerism and steric hindrance. VII. A study of the α -isopropylcyclopentanols. G. VAYON AND A. APCHÉ. *Bull. soc. chim.* 43, 667–77 (1928); cf. *C. A.* 22, 1334.—V. and A. study the relative activities of the *cis*- and *trans*-cyclopentanols. An improved method of prep. cyclopentanone (I) is by distg. adipic acid (330 g.) with barytes (35 g.) at 300° . One lot of barytes can be used for 7 charges of adipic acid. I (50 g.) is mixed with Me_2CO (400 g.) at -10° and with 18 g. of Na in 700 g. of MeOH. After 24 and 48 hrs., resp. two 50-g. portions of I were added and the mixt. allowed to stand 4 days to give 39% α -isopropylidenecyclopentanone (II), $b_{1.1}$ 78–9°. At the same time cyclopentylidenecyclopentanone, $b_{1.1}$ 115–8°, diisopropylidenecyclo-

pentanone, m. 41°, and isopropylidenecyclopentylidenecyclopentanone, m. 37°, are also formed. II in an equal wt. of alc. is reduced with Pt black to give *isopropylcyclopentanone* (III), b_1 , 67°, b_{700} 174°; oxime b_1 , 121°, m. 43°. Hydrogenation of III with Na in alc. gives 85% *trans- α -isopropylcyclopentanol* (IV), b_{27} 93–4° d_4^{25} 0.910, n_D^{25} 1.4583, purified by formation and sapon. of the phthalate. IV with $(\text{CH}_2\text{CO})_2\text{O}$ gives the *trans-deriv.*, d_4^{25} 1.073, n_D^{25} 1.463. IV with PhNCO gives a *trans-phenylurethan*, m. 63°. Hydrogenation of III with Pt black in HOAc contg. 10% HCl gives a mixt. of the *cis-trans* alcs. Formation of the phthalate and partial sapon. leaves the ester of the *cis-form*, m. 105°. Sapon. gives *cis- α -isopropylcyclopentanol* (V), b_{20} 84–5°. V on heating in N_2 at 190° is partially converted to IV. V with PhNCO gives *cis-phenylurethan*, m. 103°, *cis-succinic acid deriv.*, m. 48–9°. V is esterified about 3 times more slowly than IV.

D. H. POWERS

Bicyclic lactones of hydroaromatic and cyclopentane series. JULIUS V. BRAUN AND WILHELM MÜNCH. Univ. Frankfurt *Ann.* 465, 52–72 (1928).— Δ^1 -Cyclohexene-acetic acid, m. 37°, b_{12} 140° without decompn.; it may be heated to boiling for some time in vacuum without change; lactone formation occurs with H_2SO_4 . The Δ^1 - α -acid, $(\text{CH}_2)_5\text{C}:\text{CHCO}_2\text{H}$, heated 10 hrs with 10 mols. NaOH (10% soln.), gives 40% of the Δ^1 -acid. $(\text{CH}_2)_5\text{C}(\text{OH})\text{CH}_2\text{CO}_2\text{Et}$, heated 2 days with 5 parts HBr-AcOH, then treated 1 day with an equal wt. of Zn dust and the product distd. at 14 mm., gives 90% of $(\text{CH}_2)_5\text{CHCH}_2\text{CO}_2\text{H}$, whose Et ester, b_{14} 100–1°, and 6% of the lactone, $\text{C}_8\text{H}_{10}\text{CH}_2\text{CO}_2\text{O}$, b_{13} 129–30°, d_4^{25} 1.0913, n_D^{25} 1.4784; the lactone is sol. in warm NaOH,

from which mineral acids ppt. the HO acid; oxidation gives 70% of adipic acid; if the oxidation product is esterified with HCl and EtOH, there results in addn. to the adipic ester, 36% of an ester, $\text{C}_{15}\text{H}_{20}\text{O}_6$, b_{12} 182–7°. Δ^1 -Cyclohexenesobutyric acid, m. 69–71°, may also be distd. in vacuum without change (b_{13} 150°); with HBr-AcOH, Zn dust and finally alkali, there results about 30% of *cyclohexylisobutyric acid*, m. 62–3°, and 70% of the lactone, $\text{C}_{10}\text{H}_{14}\text{O}_2$, m. 30°. Δ^2 -Cyclopentenylacetic acid, with H_2SO_4 , gives 50% of the lactone $\text{C}_7\text{H}_{10}\text{O}_2$, b_{14} 126–7°, d_4^{22} 1.113, n_D 1.4778; oxidation with HNO_3 gives glutaric acid. *o*-Methylcyclohexylacetic acid, with HBr, AcOH and Zn, gives the γ -HO acid, $\text{C}_8\text{H}_{16}\text{O}_4$, m. 107°, at temps. above 80° it gradually loses H_2O , forming the lactone, more easily obtained by distg. the original reaction product at 13 mm.; 3% of the distillate is 2-methylcyclohexylacetic acid, b_{13} 145–7°, while the remainder is the lactone, $\text{C}_9\text{H}_{14}\text{O}_2$, b_{113} 136–7°, d_4^{19} 1.0680, n_D^{19} 1.4764; reduction with Na and EtOH gives

70% of the glycol, $(\text{CH}_2)_4\begin{array}{c} \text{C}(\text{OH})\text{Me} \\ | \\ \text{CHCH}_2\text{CH}_2\text{OH} \end{array}$, b_{13} 153–5°, m. 75–6°; heated with 60%

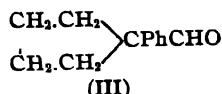

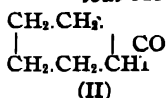

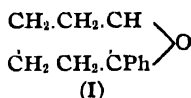

H_2SO_4 at 100°, there results 65% of a fraction, b_{18} 70–85°, b 175–6°, d_4^{27} 0.9372, n_D

1.4602, which is probably $(\text{CH}_2)_4\begin{array}{c} \text{H} \\ | \\ \text{C} \cdot \text{CH}_2 \cdot \text{CH}_2 \\ | \quad \diagup \quad \diagdown \\ \quad \quad \text{O} \quad \quad \quad \\ | \quad \quad \quad \quad \quad \\ \text{C} - \text{CH}_3 \end{array}$ The higher fraction, b_{18} 160–70°, has the

same compn. and is probably formed from several mols. of the glycol by the removal of H_2O . Et menthenacetate, b_{10} 135–7°, d_4^{17} 0.9518, $[\alpha]_D^{17}$ 32.79°, n_D^{17} 1.4642, with KOH gives about 20% of a lactone; with HBr and Zn, there results 4% of menthylacetic acid, b_{10} 164–6°, the remainder being a mixt. of lactones; of this 8–15% is solid, *lactone A*, $\text{C}_{15}\text{H}_{20}\text{O}_3$, b_{10} 156–9°, m. 114–5°, $[\alpha]_D^{16}$ ($\text{C}_6\text{H}_5\text{N}$) –24.68°; warm alkali gives an oily HO acid; Na and EtOH give the glycol, $\text{C}_{12}\text{H}_{24}\text{O}_2$, m. 94°, $[\alpha]_D^{23}$ 9.7° ($\text{C}_6\text{H}_5\text{N}$); the *lactone B*, $\text{C}_{13}\text{H}_{20}\text{O}_2$, b_{10} 156–9°, d_4^{17} 1.0153, $[\alpha]_D^{17}$ –3°; in $\text{C}_6\text{H}_5\text{N}$, $[\alpha]_D^{16}$ –30.6°. Reduction gives a glycol, $\text{C}_{12}\text{H}_{24}\text{O}_2$, b_{10} 163–6°, m. 108°, $[\alpha]_D^{18}$ 20° ($\text{C}_6\text{H}_5\text{N}$); with 60% H_2SO_4 at 100°, there results the γ -oxide, $\text{C}_{10}\text{H}_{18}\text{O}$, b 94–6°, d_4^{19} 0.9292, n_D^{19} 1.4700, $[\alpha]_D^{19}$ 23.4°.

C. J. WESS

The conversion of a six-carbon ring to a five-carbon ring through molecular rearrangement by isomerization of the phenylcyclohexene and phenylmethylcyclohexene oxides. (MLLE.) JEANNE LEVY AND J. SFRAS. *Compt. rend.* 187, 45–7 (1928).—1-Phenylcyclohexene oxide (I), b_{18-14} 136°, n_D 1.5494, d_4 1.0768, prepd. by action of BzO_2H on the hydrocarbon, isomerizes in the presence of a trace of ZnCl_2 to give 60% (II), and 9% (III), b_{18-14} 134°; semicarbazone, m. 196.5°. In a similar fashion 1-phenyl-

4-methylcyclohexene oxide, m. 36°, b_{16} 140-1°, isome. methyl-2-cyclohexanone and 2% 1-phenyl-3-methyl-1-cyctes to yield 55% 1-pentopentanaldehyde

Chaulmoogryl derivatives of lactates and salicylates. [SIMEON, D. H. PO AUGUSTUS P. WEST. Univ. of the Philippines and Bur. of Science, Manila. *SANTIA J. Sci.* **35**, 405-9(1928).]—The following chaulmoogryl derivs of OH acid ϵ . Ph prepd. by treating the corresponding ester with chaulmoogryl chloride for 4 ste about 140-80° and crystg. from MeOH with bone black: *Me chaulmoogryllacta*, 51-4° (38% yield); *Et chaulmoogryllactate*, m. 54-7° (33% yield); *Et chaulmo salicylate*, m. 48-51° (16% yield); *Bu chaulmoogrylsalicylate*, m. 49-50° (27% yic These esters decomp. readily on standing in warm weather. DAVID DAVIDSON

Effects induced by the phenyl group. I. Addition of polar reagents to sty and the behavior of the halogenated ethylbenzenes. FRANK ASHWORTH AND GEO N. BURKHARDT. Univ. of Manchester. *J. Chem. Soc.* **1928**, 1791-802.—Pos (*Ber.* **38**, 646(1905)), from his expts., deduced that PhSH added to PhCH₂CH₂ in opposite sense to HBr. The present work was to test his conclusion. HBr and PhC CH₂ give only PhCHBrCH₂. NH₄HSO₃ and PhCH₂CH₂ emulsified with kieselguhr shaken for 10 days, and, after filtration, boiled with Ba(OH)₂, give *Ba α-phenyletha sulfonate*, crystg. with 2H₂O, which was also obtained from PhCHBrMe and (NH SO₃). The *Ba salt* of the β-deriv. crysts. with 1H₂O. PhSH and PhCH₂CH₂ give, af oxidation, PhCH₂CH₂SO₂Ph, identical with that prepd. from PhCH₂CH₂Br by boil with PhSO₂Na; the sulfones could not be prepd. from PhCHClCH₂, which ge PhCH₂CH₂ or from PhCH₂CH₂Cl, which was unchanged. Pure PhCH₂CH₂SPh a PhCH(SPh)Me were prepd. by heating PhSNa with the corresponding Br deri the α-deriv., b_{16} 163-4°, n_D 1.6042; the β-deriv., b_{16} 188-9°, n_D 1.6082; in the react between PhCH₂CH₂ and PhSH there was formed less than 2% of the α-isomer. The velocity of the reaction was followed in the light and in darkness; in the light the reaction is practically complete in 1.5 days; in the dark the reaction is not complete af 25.5 days. The rate was also followed cryoscopically, with similar results. The acti of EtOH-KOH on PhCHBrCH₂Br gives at least 92% of the PhCHBrCH₂. PhCH CHBr is very stable towards HCO₂H, which may be used as a means of detecting t β-Br when mixed with the α-Br isomer. PhCHBrMe and EtOH-KOH give PhM CHO, while PhCH₂CH₂Br gives PhCH₂CH₂. C. J. WEST

Dichloro-o-xylenes. LEONARD E. HINKEL, ERNEST E. AYLING AND LILLI COLLIER BEVAN. Univ. College, Swansea. *J. Chem. Soc.* **1928**, 1874-8.—Cl, pass into o-C₆H₄Me₂ at -10° (Fe filings) until the gain in wt. corresponded to 2 atoms of Cl gave a mixt. from which were isolated the 3,6-di-Cl deriv. (I), m. 68°, b. 227° (all b. 1 cor.); the 3,4-di-Cl deriv. (II), m. 9°, b. 234°; and the 4,5-di-Cl deriv. (III), m. 76°, 240°. Each of these yields a tetra-Cl deriv. (IV), m. 227°. With 3 vols. fumi HNO₃ and 1 vol. AcOH, III yields the 3-NO₂ deriv. (V), m. 117°; with H₂SO₄ and HN it gives the 3,6-di-NO₂ deriv. (VI), m. 210°. Reduction of V with Fe and AcOH giv 4,5-dichloro o-3-xylidine, m. 88° (*Ac deriv.*, m. 197°); the diazo soln. with CuCl gives mixt. of the 3,4,5-tri-Cl deriv., m. 96°, and IV. Reduction of VI with NaHSO₃ giv the 3,6-di-NH₂ deriv., m. 186°. II yields a 5-NO₂ deriv., m. 78°, and a 5,6-di-NO₂ deri m. 172°. 5,6-Dichloro-o-4-xylidine, m. 63° (*Ac deriv.*, m. 147°); 3,4-dichloro-5, diamino-o-xylene, m. 176°. I yields a 4-NO₂ deriv., m. 95°, and a 4,5-di-NO₂ deriv., r 220°. 3,6-Dichloro-o-4-xylidine, m. 82° (*di-Ac deriv.*, m. 141°). 3,5-Dichloro-4-nitr o-xylene, m. 92°, the 4-NH₂ and 4-AcNH derivs m. 47.5° and 196° (cf. Crossley, *Chem. Soc.* **81**, 1536(1902)). C. J. WEST

Reactivity of halogens in aromatic linkage. H. LINDEMANN AND A. PABST. *Ann* **462**, 24-47(1928).—Nitration of m-BrC₆H₄Me with concd. H₂SO₄ and fuming HNO gives 2,4-dinitro-5-methylbromobenzene, m. 114°. Nitration of 2,4-BrMeC₆H₃CN wit concd. H₂SO₄ and KNO₃ gives 2-bromo-4-methyl-3,5-dinitrobenzonitrile, m. 165°, saponi the corresponding benzoic acid, m. 235°, better prepd. by nitration of 2,4-BrMeC₆H CO₂H; chloride, m. 111°; *Et ester*, m. 93°; *azide*, m. 101°, explodes on rapid heating heating in AcOH (1:1) gives 2-bromo-4-methyl-3,5-dinitroaniline, m. 170° (*Ac deriv* m. 151°); heating with EtOH gives the phenylurethan, m. 122°. Through the diaz reaction, the amine gives 2,4-dinitro-3-methylbromobenzene, m. 86°, which does not reac with PhNH₂. 2-Chloro-4-methyl-3,5-dinitrobenzoyl chloride, m. 106°; *azide*, m. 97

(decompn.); 2-chloro-4-methyl-3,5-dinitroaniline, yellow, m. 173° (*Ac deriv.*, m. 154°); 2,4-dinitro-3-methylchlorobenzene, pale yellow, m. 77°, unchanged by PhNH_2 . Catalytic reduction of 1-hydroxy-2-chloro-3-indone gives 1,3-indandione, m. 131°. The following spectrochem. data are given: 5,2,4-Me(O₂N)₂C₆H₂Cl, $d_4^{25.2}$ 1.4054, n 1.55341, 1.58002, for α and β at 99.2°; 6,2,4-Me(O₂N)₂C₆H₂Cl, $d_4^{100.8}$ 1.3999, n 1.54762, 1.57342 (α and β at 100.8°); 3,2,4-Me(O₂N)₂C₆H₂Cl, $d_4^{98.9}$ 1.3896, n 1.53398, 1.55660 (α and β at 98.9°); 2,4-(O₂N)₂C₆H₂Cl, $d_4^{99.4}$ 1.4717, n 1.55819, 1.58586 (α and β at 99.4°). The transformation of the addn. compd. of 2,4-(O₂N)₂C₆H₂Cl and α -C₁₀H₇NH₂ into the 2,4-nitrodiarylamine in boiling EtOH is not a monomol. reaction; the value of k , calcd. from the formula $k = (1/t) \ln [a/(a-x)]$ shows a continual decrease with time; the reaction velocity is independent of the concn. The mol. wt. of this addn. product in freezing C₆H₆ is only half of the theoretical value. The reaction velocity of the various nitrochlorobenzenes with PhNH_2 in EtOH was also detd. The Me-free derivs. show the greatest velocity; the 5-Me derivs. react less readily, the 6-Me deriv. still more slowly, while the 3-Me derivs. do not react at all.

C. J. WEST

Rearrangement of stereoisomeric hydrazones. JOHN XANTHOPOULOS. *Abstracts of Theses, Univ. Chicago, Science Series 4*, 195-201(1925-6) (publ. May, 1928); cf. *Ibid. Series 3*, 111-8(1924-5).—Two pairs of stereoisomeric hydrazones of the type $\text{RR}'\text{C}=\text{NNH}_2$ (R and R' = aryl radicals) were prepd. and their rearrangement studied. *Stereoisomeric p-bromobenzophenone hydrazones* (from $p\text{-BrC}_6\text{H}_4\text{COPh}$ and NH_2NH_2); α -form (I) m. 166-7°, β -form (II), m. 102.5-3.5°. The reaction product was sepd. into the isomers by means of CHCl_3 and ligroin. *p-Bromobenzophenone ketazine* was obtained as a by-product in the prepn. of the hydrazone. *Stereoisomeric p-chlorobenzophenone hydrazones* (from $\text{ClC}_6\text{H}_4\text{COPh}$ and NH_2NH_2); α -form (III), m. 154-5°, β -form (IV), m. 105-6°. MeOH was used as the sepg. agent; it dissolves principally the β -form, while the residue consists of the almost pure α -form. Evapn. of the MeOH soln. and further treatment with CHCl_3 and ligroin gives the β -form. For the rearrangement expts., several portions of 0.5 g. of II were mixed with ZnCl_2 in Pyrex flasks and heated to 450° for 2 to 3 min. and the cool melt was extd. in succession with dil. HCl and Et₂O. Analysis of the Et₂O soln. gave 13 mols. of $p\text{-BrC}_6\text{H}_4\text{CO}_2\text{H}$ (V) and 70 mols. of BzOH , per 100 mols. of II. The acid soln. yielded 69 mols. of $p\text{-BrC}_6\text{H}_4\text{NH}_2$ (VI) and 14 mols. of PhNH_2 per 100 mols. of II. The rearrangement of I, carried out in a similar way, gave 61 mols. of V, 11 mols. of BzOH , 16 mols. of VI and 59 mols. of PhNH_2 . In the case of III, 55 mols. of $p\text{-ClC}_6\text{H}_4\text{CO}_2\text{H}$ (VII), 15 mols. of BzOH , 20 mols. of $p\text{-ClC}_6\text{H}_4\text{NH}_2$ (VIII), and 60 mols. of PhNH_2 were obtained; while IV yielded 18 mols. of VII, 66 mols. of BzOH , 54 mols. of VIII and 12 mols. of PhNH_2 . The formation of the acids is caused by hydrolysis of the primarily formed nitriles. The rearrangement of the hydrazones involves 2 reactions: $\text{RR}'\text{C}=\text{NNH}_2 = \text{RC}:\text{N} + \text{R}'\text{NNH}_2$ and $\text{RR}'\text{C}=\text{NNH}_2 = \text{R}'\text{C}:\text{N} + \text{RNH}_2$. The differences in the quantities of the resp. products of rearrangement are due to the structural influence of the resp. isomer.

G. SCHWACH

Preparation and rearrangement of methylphenylmethylchloroamine. ANDREW MCN. NEFF. *Abstracts of Theses, Univ. Chicago, Science Series 4*, 141-9(1925-6) (publ. May, 1928); cf. *Proc. Nat. Acad. Sci.* 1, 196(1915).—A study on the rearrangement of methylphenylmethylchloroamine (I) (from $\text{MePh}_2\text{CNH}_2\cdot\text{HCl}$ in H_2O and aq. Na_2CO_3). When I was heated with soda-lime to about 200°, rearrangement occurred. Hydrolysis of the product of rearrangement gave NH_3 , PhNH_2 , and Ph_2CO . MeNH_2 could not be found; also other expts. carried out between 150° and 200° likewise failed to produce MeNH_2 . In the expts. carried out below 150°, rearrangement of I took place in EtONa in boiling EtOH, in Ph_2Hg in boiling xylene, and in boiling xylene. Hydrolysis yielded PhNH_2 , MeCOPh and Ph_2CO . No MeNH_2 was produced. N. concludes that on account of a rather large yield of PhNH_2 , the Ph group is more easily removed from the MePh_2C radical than the Me group. A general theory for the relative ease of migration is given.

G. SCHWACH

Preparation, rearrangement and reduction of β -methylphenylmethylhydroxylamine. MARY E. MAVER. *Abstracts of Theses, Univ. Chicago, Science Series 4*, 111-6(1925-6) (publ. May, 1928).—The rearrangement of $\text{MePh}_2\text{CNHOH}$ was studied in order to test Neff's hypothesis (preceding abstr.) concerning the ease of migration of radicals in mol. rearrangements. *β -Methylphenylmethylhydroxylamine* (I) (from MePhC:NOH and PhMgBr), m. 112-3°. It reduces alk. AgNO_3 and Fehling soln., and, in alc., it changes the color of FeCl_3 soln. to dark brown. *HCl salt*, m. 196°. *Chloroplatinate*, orange, rhombohedral crystals, decomp. 165°. *Bz deriv.*, $\text{MePh}_2\text{CNBzOH}$

(II), m. 183°. In alc., II darkens FeCl₃ soln. Reduction of I with HCl and Zn gives MePh₂CNH₂. When II is heated with soda-lime for 20 min. at 230–50°, rearrangement takes place, yielding almost quant. Ph₂C:NMe (III) and BzONa. Hydrolysis of the product of rearrangement gives only Ph₂CO and MeNH₂. Also treatment of I with PCl₅ gave III only. M. concludes that in these rearrangements only the Me group is migrating, which result does not confirm Neff's hypothesis. G. SCHWOCH

N,N'-Diphenyl-*o*-phenylenediamine. CHARLES S. GIBSON AND JOHN D. A. JOHNSON. Univ. of London. *J. Chem. Soc.* 1928, 1988–9.—The compd. of Wieland and Müller (*C. A.* 8, 346) stated to be C₁₄H₁₄(NHPh)₂ is really *o*-H₂NC₆H₄NPh₂ as suggested by Clermo, Perkin and Robinson (*C. A.* 19, 293). The latter compd., prep'd. according to W. and M., behaves as a primary amine towards HNO₂ and yields an Ac deriv., m. 131–2°. C. J. WEST

Phenacylhydrazine. M. BUSCH, WILH. FOERST AND W. STENGEL. Univ. Erlangen. *J. prakt. Chem.* 119, 287–302(1928).—BzCH₂Br (24 g.) and 15.2 g. NH₄H₂O in 180 cc. abs. EtOH at –5° give 60% of phenacylhydrazine (I), m. 85–6° (decompn.); it is stable for only a short time at room temp., but may be kept at 0° for several days, depending upon its purity; at 50° NH₃ is split off; held at 60° until NH₃ is completely evolved, a dark brown mass is obtained, from which no definite product could be isolated. I gives clear solns. in mineral acids but EtOH-HCl gives a dark yellow to brown soln., from which Et₂O pptts. a slimy mass. Oxalate of I, m. 149–50° (decompn.). Warmed with EtOH at 60° there results 2,5-diphenyl-3-keto-3,4-dihydropyrazine (II). I and Ac₂O give the *di-Ac* deriv., m. 123°. *o*-Nitrobenzalphenacylhydrazone, yellow, m. 156° (decompn.); *m*-NO₂ deriv., canary-yellow, m. 146–7°; *o*-HO deriv., m. 110° (decompn.). *p*-Bromophenacylhydrazine, m. 135–6° (decompn.); in EtOH it behaves as I and probably gives the 2,5-*di-p*-bromophenyl deriv. of II, m. 248–9°. HCl salt of II, pale rose, turns brown at 170° and m. 210°; perchlorate, m. 270°; the oxalate is practically insol. in H₂O. *o*-Hydroxybenzal-*p*-bromophenacylhydrazone, m. 125° (decompn.). EtOH-NaOH gives a red-brown soln. *m*-nitro deriv., yellow, m. 136° (decompn.); *p*-Cl deriv., orange, m. 134° (decompn.) (phenylhydrazone, yellow, m. 214° (decompn.)); the latter with BzH gives 2,3-diphenyl-5-bromophenyl-1-chlorobenzoalaminol-1,3,4-triazine tetrahydride, yellow, m. 163–4°, while HCHO gives 3-phenyl-5-bromophenyl-1-chlorobenzoalaminol-1,3,4-triazine, m. 180° (decompn.); the analogous compd from AcH m. 166°. *m*-Nitrophenacylhydrazine, m. 100° (decompn.); this did not condense with *p*-ClC₆H₄CHO. C. J. WEST

δ -Substituted semicarbazides. I. V. HOPPER. *J. Roy. Tech. Coll. Glasgow* 1927, No. 4, 48–57; cf. *C. A.* 16, 2481.—An improved method of prep'g δ -substituted semicarbazides is described. A temp. of about 130° instead of 180° was found to be sufficient to produce the reaction: $>C=NNHCONH_2 + RNH_2 = >C=NNHCONHR + NH_3$ (RNH₂ = aromatic amine), thus avoiding the formation of by-products and increasing the yield of the intermediate semicarbazone. On heating or by reaction with I the free semicarbazides decompose, forming *sym*-substituted carbamylhydrazines. The HCl salts give oxalates with (CO₂H)₂, azides with HNO₂, Cu derivs. with CuCl₂. δ -Benzylsemicarbazide (I) (80% from 20 g. PhCH₂NH₂ and 20 g. Me₂C=NNHCONH₂). *Ac* deriv., m. 145°. Oxalate, m. 135° (decompn.). Benzylcarbamazide, m. 84°, not explosive. CuCl deriv.—To a soln. of 1.5 g. CuCl₂ in 15 cc. cold H₂O was added 2 g. of the HCl salt of I in 20 cc. cold H₂O. After 1 min., pptn of blue prismatic needles occurs, which were quickly filtered off. The filtrate deposited the compd. PhCH₂NHCON(CuCl)NH₂HCl 4 5H₂O, olive-green plates. The blue substance (II) was very unstable, treatment with abs. EtOH or standing at warm temp. converting it into the green compd. (III). Probably, II is a higher hydrate than III. *sym*-Dibenzylcarbamylhydrazine, m. 237°. *dl*- δ - α -Phenylethylsemicarbazide (65% from MePhCHNH₂ and Me₂C=NNHCONH₂), m. 92° (decompn.). Oxalate, m. 160° (decompn.). *dl*- δ - α -Phenylethylcarbamazide, m. 87°. *sym*-Di- α -phenylethylcarbamylhydrazine, m. 187°. CuCl deriv., olive-green laminas, very unstable *di*- δ - α -Phenylethylsemicarbazide is an oil (IV). *d*- δ - α -Phenylethylcarbamazide, m. 73°, [α]_D¹⁷ 243.7° in abs. EtOH. δ -Phenylsemicarbazide. Oxalate, decomps. 165°. CuCl deriv., light green, rather stable. Benzaldehyde *d*- δ - α -phenylethylsemicarbazone (from BzH and HCl salt of IV) m. 102°, [α]_D¹⁸ –296.9° in EtOH. Semicarbazide oxalate, m. 146°, from H₂NCONHNH₂·HCl and (CO₂H)₂. G. SCHWOCH

The mechanism of the substitution of bromine in the aromatic hydrazones. II. VANGHELOVICI. *Bul. soc. chim. România* 9, 59–67(1927); cf. *C. A.* 22, 1341.—The bromination product of PhNHN:CHPh (I), is believed to be 2,4-Br₂C₆H₃NHN:CBRPh (II), rather than 2,4-Br₂C₆H₃NHN:CHC₆H₄Br (*p*), the formula assigned by Ciusa

(*C. A.* 10, 2893), because the condensation product *m.* 125.5° of 2,4-Br₂C₆H₃NHNH₂ with *p*-BrC₆H₄CHO has entirely different properties. II with KCN gives a CN deriv. indicating labile Br. The bromination of I is believed to occur as follows: I → *p*-BrC₆H₄NHN·CHPh → 2,4-Br₂C₆H₃NHN·CHPh → 2,4-Br₂C₆H₃NHNBr·CHBrPh → 2,4-Br₂C₆H₃NHN·CBrPh + HBr. With Cl₂ a similar reaction takes place. I in AcOH with Br₂ gives II, *m.* 114°. II with boiling alc. KCN gives the CN deriv., *m.* 138°. *o*-HOC₆H₄CHO with *p*-BrC₆H₄NHNH₂ in AcOH gives the *hydrazone*, *m.* 175°. *p*-O₂NC₆H₄NHN·CHPh with Br₂ gives 2,4-Br(ON)₂C₆H₃NHN·CBrPh, *m.* 169°. On treating with KCN the CN deriv., *m.* 90°, seps. I in AcOH at 0° is treated with Cl₂ gas to give 2,4-Cl₂C₆H₃NHN·CClPh, *m.* 87°; with KCN 2,4-Cl₂C₆H₃NHN·C(CN)Ph, *m.* 128°. PhNIIN:CHC₆H₄OMe(*p*) with Cl₂ gives 2,4-Cl₂C₆H₃NHNCClC₆H₄OMe, *m.* 111°. With KCN in EtOH the CN deriv., *m.* 150°, is obtained. D. H. P.

Relative reactivities of butyl bromide and bromobenzene towards magnesium in ether. HENRY GILMAN AND F. A. ZOELLNER. Iowa State College. *J. Am. Chem. Soc.* 50, 2520-3 (1928).—BuBr reacts more rapidly than PhBr with Mg in Et₂O; by using 0.5 mole, the % of RMgX formed after 45 sec. is: BuBr, 53.7; PhBr, 36.9; after 90 sec., BuBr, 65.4; PhBr, 51.7. This result is of direct value in connection with some theories proposed to account for orientation in the C₆H₅ nucleus. C. J. WEST

The characterization of the —OMgX group. HENRY GILMAN AND F. SCHULZE. Iowa State College. *Rec. trav. chim.* 47, 752-60 (1928).—The reaction between several org. compds. and Grignard reagents often can take place in more than 1 way and therefore a search is made for a reagent which will react with the primary product to give a compd. indicating the position taken up by the —OMgX group. The reaction between Ph₂C·CO and PhMgBr, which gives rise to the formation of Ph₂C·CPhOH, may involve an addn. to the C:O group or to the C:C, the reaction product being the same in both cases. On treating the primary reaction product with BzCl Ph₂C·CPhOBz is formed, thus showing that the Grignard reagent has added to the C·O group (*C. A.* 14, 1831). In the reaction of PhNCO with PhMgBr, BzCl does not react with the primary reaction product; with PhNCS and the same Grignard reagent, however, it does, showing that addn. has taken place at the C·S group (*C. A.* 18, 1992). By analogy, therefore, it is reasonable to conclude that with PhNCO addn. takes place at the C:O group. In this case also Me and Et iodide, allyl bromide Ph₂CHBr, Ph₂CCl, *p*-O₂NC₆H₄CH₂Br and Et₂SO₄ were tried under various conditions, but there was no apparent replacement of the —OMgBr group. It is an easy matter to replace the —MgX group attached to C, N and S by other groups which give products that are conveniently identified; for this purpose one can use Et₂SO₄, alkyl sulfonates, org. halides that have a highly active halogen atom (*e. g.*, allyl bromide), acid chlorides, acid anhydrides and PhNCO. Despite the researches of Kohler and Houben it is impossible to select any compd. or class of compds. that can be used generally to characterize the —OMgX group; in addn. to acid halides, acid anhydrides and some alkyl halides, with a highly reactive halogen atom, already used previously by others, they found PhNCO, phenylcarbamine chloride and bromide highly effective with certain types of —OMgX compds. They found the —OMgCl group more readily replaceable than the —OMgBr group and the —OMgI group the least satisfactory, and recommend that media of higher *b. p.* than that of PhMe be not used, several ROMgX compds. readily decompose at higher temps. Compds. with large R groups and those derived from secondary and tertiary alcs. undergo less ready reaction than simpler types. When a case arises where it appears impossible to replace the —MgBr group, attached to O, one can have recourse to 3 expedients: (a) the S analog can be used; (b) an organometallic compd. can be used that has a more positive element like the Na alkyl compds.; (c) from the impossibility of replacing the —MgBr group one can conclude that it is attached to O; this risk is hardly as great as it appears, inasmuch as the —MgX group attached to other frequently occurring elements (C, N, S) undergoes ready replacement. The following reactions were investigated experimentally: Ph₃COMgBr with Ac₂O, no reaction; Ph₂CHOMgBr with Bz₂O → Ph₂CHOBz, other reagents not replacing the —MgBr group in this compd.; BuOMgI with allyl iodide, no reaction; phenoxy-, benzyloxy-, diphenylmethoxy- and triphenylmethoxymagnesium bromide did not give the desired reaction with PhCH₂Br; PhOMgBr and Ph₂CCl gave a small quantity of *p*-HOC₆H₄·CPh₃; BuOMgBr and PhNCO gave 80% of PhNHCO₂Bu; PhOMgBr and PhCH₂OMgBr gave with PhNCO 70% of Ph and benzyl phenylcarbamate, resp.; but diphenyl- and triphenylmethoxymagnesium bromide did not react. With phenylcarbamine chloride and bromide Ph₂CHOMgBr did not react but PhCH₂OMgBr gave 70% of PhNHCO₂CH₂Ph with the former. COCl₂ and NH₃ sometimes give rise to the formation of urethans (Yoder, *C. A.* 17, 1429), but with PhCH₂OMgBr this reaction does not

take place. PhOMgBr and EtOMgBr did not give the desired reaction products with benzoyl bromo amide, while no reaction occurred between PhOMgBr and SOCl_2 , chloromethyl ether, CH_2N_2 and PhCN_2 , and between $\text{PhCH}_2\text{OMgBr}$ and BrCH_2OEt . A small yield of AcOPh was obtained from PhOMgBr and ketene and a small yield of Ph_2CHCl from $\text{Ph}_2\text{CHOMgBr}$ and PCl_3 . Again a reaction did not occur between PhOMgBr , Ph_3COMgBr , Ph_2CHOCaI , Ph_3COCaI , Ph_2CHOZnI , Ph_2COZnI and Et_2SO_4 . There was no appreciable replacement with the following combinations: PhCH_2Cl with PhOMgBr ; PhNCO with bromomagnesium benzoate; PhNCS with EtOMgI and BuOMgI ; diphenylcarbamine chloride with EtOMgBr ; chloro- and bromoacetophenone with PhOMgCl and PhOMgBr ; NH_3 with PhOMgI ; ethylene oxide with BuOMgI and PhOMgI ; ZnEt_2 with $\text{Ph}_2\text{CHOMgBr}$. Finally it was shown that PhCH_2OPh was split by MgBr_2 on refluxing during 48 hrs in C_6H_6 , besides the unchanged ether, PhCH_2Br , phenol and a high-boiling product being obtained. On boiling the same components in Et_2O during 46 hrs. a reaction does not take place.

C. F. VAN DUIN

Arylsulfonylphenylchloroamides. ERICH GEBAUER-FÜLNEGG AND EGON JUSA. Univ. Wien. *Monatsh.* 50, 61-7(1928).—A study is recorded of the reactions of $\text{PhSO}_2\text{N-ClPh}$ upon electrolysis in liquid SO_2 , with $\text{C}_6\text{H}_5\text{N}$, concd KOH , MeONa , Na in Et_2O , liquid NH_3 , Hg , Zn , NaI in Me_2CO , NaNO_2 in CHCl_3 , NaCN in Me_2CO and AlCl_3 in CS_2 ; the end products consist of *o*- and *p*-substituted arylsulfanilides; the position of the Cl depends upon the reaction of the medium.

C. J. WEST

Preparation of derivatives of phenolsulfonyl chloride. ERICH GEBAUER-FÜLNEGG AND FRANZ V. MEISSNER. Univ. Wien. *Monatsh.* 50, 55-60(1928).— PhOMe (10 g.) and 150 g ClSO_3H , allowed to stand overnight, give about 20% of *anisole-disulfonyl chloride*, m. 86° ; *amide*, m. $239-40^\circ$; *anilide*, m. 209° ; reduction of 5 g. of the crude chloride with Zn and H_2SO_4 gives 1.5 g. of *dimercaptoanisole*, m. 51° . PhOEt (5 g.) and 80 g. ClSO_3H give 0.2 g. of the disulfonyl chloride, m. $104-7^\circ$. PhSMc yields a disulfonyl chloride, whose *anilide*, m. $202-4^\circ$. $\text{C}_6\text{H}_5(\text{OH})(\text{SO}_2\text{Cl})_2$ and Ac_2O give 90% of *phenyl acetate-disulfonyl chloride*, m. 91° . In attempting to prep. the anilide, sapon. occurs. *m-Cresol acetate-disulfonyl chloride*, m. 109° (85% yield). PhSAc and ClSO_3H give *(p-ClO}_2\text{SC}_6\text{H}_4)_2\text{S}_2, m. 131° .*

C. J. WEST

Isomerization of a few ethylene oxides. ROGER LAGRAVE. *Ann. chim.* 8, 363-446

(1927).—Several oxides of the type $\text{Ph}_2\text{C}(\text{OCHR})_2$ have been prepd; heating isomerizes them generally to an aldehyde Ph_2RCCHO or to a ketone Ph_2HCCOR . The oxides have been obtained from the corresponding ethylenic hydrocarbons with BzO_2H . Oxides, $\text{Ph}_2\text{C}(\text{OCHR})_2$; $\text{R} = \text{Me}$, m. 34° , b_{21} $178-80^\circ$, d_4^{20} 1.1038 (supercooled liquid),

n_D^{15} 1.5755 (supercooled), isomerizes exclusively to Ph_2CHCOMe , whose oxime m. 165° ; *Et*, b_{18} $175-80^\circ$, d_4^{20} 1.114, n_D^{15} 1.5790, isomerizes to 85% Ph_2CHCOEt and 15% Ph_2EtCCHO ; *CHMe}_2*, b_{20} $182-3^\circ$, d_4^{20} 1.0507, n_D^{15} 1.5550, isomerizes to 18% $\text{Ph}_2\text{C}(\text{CHMe}_2)\text{CHO}$ and 82% $\text{Ph}_2\text{CHCOCHMe}_2$; *Pr*, b_{10} $175-80^\circ$, d_4^{20} 1.054, n_D^{15} 1.5595, gives exclusively Ph_2CHCOPr ; *CH}_2\text{CHMe}_2*, b_{17} $196-7^\circ$, d_4^{20} 1.035, n_D^{15} 1.5555, isomerizes to 20% $\text{Ph}_2\text{C}(\text{CH}_2\text{CHMe}_2)\text{CHO}$ and 80% $\text{Ph}_2\text{CHCOCH}_2\text{CHMe}_2$; *Bu*, b_{17} $195-7^\circ$, d_4^{20} 1.037, n_D^{15} 1.5485, gives 23% Ph_2BuCCHO and 77% Ph_2CHCOBu ; *CH}_2\text{Ph}*, m. 69° , gives 58% $\text{Ph}_2(\text{PhCH}_2)\text{CCHO}$ and 42% $\text{Ph}_2\text{CHCOCH}_2\text{Ph}$; *Ph*, m. 77° , gives exclusively Ph_2CHCOPh . *C}_6\text{H}_4\text{OMe}*, m. 104° , gives exclusively $\text{PhCOCHPhC}_6\text{H}_4\text{OMe}$. The formation of an aldehyde from the corresponding oxide is a 1-phase migration. To ascertain that the formation of a ketone also occurs without an intermediary product, the aldehydes were heated but never did they isomerize to a ketone. The formation of the ketone is thus also considered as a 1-phase process. If H_2SO_4 is present during the heating, the isomerization is liable to occur in several directions at the same time.

A. L. HENNE

The preparation of triiodophenol from 5-iodo- and 3,5-diiodo-salicylic acid. P. BRENNAN AND CH. GIROD. *Compt. rend.* 186, 1851-2(1928).—A soln. of 2.64 g. of 5,2-I(HO) $\text{C}_6\text{H}_3\text{CO}_2\text{H}$ (I) in 40 cc. of *N* NaOH (dild. 1.5 times with H_2O) is treated with a soln. of I_2 in iodide contg. 5.10 g. of I_2 . After 1 hr. an excess of dil. H_2SO_4 is added, the I_2 is removed by adding SO_2 and the unchanged salicylic acid is pptd. by BaCO_3 . The product is crystd. from hot C_6H_6 . The yield is 2.70 g. I is obtained from 3,5,2-I $_3$ (HO) $\text{C}_6\text{H}_2\text{CO}_2\text{H}$ by a similar procedure.

REYNOLD C. FUSON

Nitration of *m*-fluorophenol. HERBERT H. HODGSON AND JOSEPH NIXON. Tech. College, Huddersfield. *J. Chem. Soc.* 1928, 1879-82.—This study follows the same lines as those for the Cl and Br derivatives. (*C. A.* 19, 2937; 20, 1064). *m*- $\text{FC}_6\text{H}_4\text{OH}$ (29 g.)

yields 6 g. of the 6- NO_2 deriv. (I) and 9 g. of the 4- NO_2 deriv. (II). I, yellow, m. 32° , is volatile in steam; Na salt, red needles; Ag salt, orange-brown; Me ether, m. 52° ; benzoate, m. $110-1^\circ$. II, m. 42° , is non-volatile in steam; Na salt, pale yellow; Ag salt, bright yellow; Me ether, m. 56.5° ; benzoate, m. 118° . 3-Fluoro-2-nitrophenol, red, m. 39° , results on nitrating the disulfonated $m\text{-FC}_6\text{H}_3(\text{OH})$ and passes over on hydrolysis and distn. with steam; Na salt, reddish brown; Ag salt, very deep reddish brown; Me ether, m. 43.5° ; benzoate, m. 114° . 3-Fluoro-4,6-dinitrophenol, m. 80° , readily volatile in steam; Ag salt, yellow needles. 3-Fluoro-2,6-dinitrophenol, m. 68.5° ; Ag salt, orange-red needles. 3-Fluoro-2,4-dinitrophenol, pale yellow, m. 138.9° ; Ag salt, deep red. The action of NH_3 at 150° is described. 3-Fluoro-2,4,6-trinitrophenol, m. 173° ; it is not very volatile with steam but sublimes slowly from boiling concd. H_2SO_4 ; Ag salt, bright yellow.

C. J. WEST

Some derivatives of 3,5-dibromo-2-hydroxy-1-methylbenzene. E. BUREŠ AND FR. POLÁK. Charles Univ., Prague. *Časopis Československého Léčárnictva* 6, 117-22, 129-35(1926); cf. C. A. 22, 63.—By action of Br at room temp., without solvent or catalyst and without access of sunlight, B. and P. were able to prep. only 3,5-dibromo-*o*-cresol, m. 57° ; this establishes the lower limit for the action of Br on *o*-cresol. The following derivs. were prepd: Me ether, m. 33.5° ; Et ether, m. 34.5° ; acetate, m. 62° . The Br ortho to OH was replaced by NO_2 by the action of NaNO_2 , while by action of concd. HNO_3 both Br were replaced. The entry of Br in the mol. of *o*-cresol increases the stability of the ring.

WILLIAM J. HUSA

2,5,6-Trichloro-4-hydroxy-1,3-dimethylbenzene. E. BUREŠ AND SV. MAREK. Charles Univ., Prague. *Časopis Československého Léčárnictva* 6, 85-91, 101-6(1926).—By chlorination of 2,4- $\text{Me}_2\text{C}_6\text{H}_3\text{OH}$ is obtained tetrachlorodixylenol (m. 164°) and 30% of 2,5,6-trichloro-4-hydroxy-1,3-dimethylbenzene, m. 169° , b. 282° . The following derivs. were prepd.: Me ether (m. 86° , b. 283°), Et ether (m. 43° , b. 288°), benzoate, (m. 98° , b. 247°), acetate (m. 86° , b. 279°).

WILLIAM H. JUSA

Some bromine derivatives of *m*-cresol. E. BUREŠ AND A. BALADA. Charles Univ., Prague. *Časopis Československého Léčárnictva* 6, 158-63, 177-90(1926).—By bromination of *m*-cresol at ordinary temp. and pressure, without solvents or catalysts, 2,4,6-tribromo-*m*-cresol (I), m. $81.6-81.9^\circ$, was obtained, thus showing that the rule of substitution valid for the NH_2 derivs. of C_6H_6 is applicable in this case. The following derivs. were prepd.: Me ether of I, m. 67° ; Et ether of I, m. 47.5° ; acetate of I, m. 68° ; $[\text{MeC}_6\text{Br}_3(\text{OH})]_2\text{Hg}$, $\text{MeC}_6\text{Br}_3(\text{OH})\text{HgOH}$, $[\text{MeC}_6\text{Br}_3(\text{OH})]_2\text{BiOH} + \text{Bi}_2\text{O}_3$, 2,4,6-tribromo-3-amino-1-methylbenzene, m. $100.6-101^\circ$; 2,4,6-tribromoacetotoluide, m. 155° ; 2,4,6-tribromo-1-methyl-3-diazobenzene sulfate, 2,6-dibromo-4-nitro-3-hydroxy-1-methylbenzene, m. 134° ; 2,4-dibromo-6-nitro-3-hydroxy-1-methylbenzene, m. 87° ; 2-bromo-4,6-dinitro-3-hydroxy-1-methylbenzene, m. 104.5° ; 2,4,5,6-tetrabromo-3-hydroxy-1-methylbenzene (II), m. 194° ; Me ether of II, m. 146° ; Et ether of II, m. 108° ; acetate of II, m. 166° ; and tetrabromo-*m*-cresol brominated in the OH group. W. J. H.

Unusual substitution reaction. I. M. V. IONESCU. *Bull. soc. stiinte Cluj* 3, 54-9(1926); cf. C. A. 21, 3202.—Condensation of dimethylidihydroresorcinol with Et benzylideneacetate by means of piperidine in abs. alc. affords benzylidenebisdimethylidihydroresorcinol, m. 192° , which is also produced from dimethylidihydroresorcinol and Et benzylidenebisacetate, and is converted by H_2SO_4 or AcOH into Vorländer's phenyltetramethyloctahydroxanthenedione, m. $200-1^\circ$ (*Ann.* 309, 375-83 (1899)).

B. C. A.

Course of the Friedel and Craft reaction with dialkylresorcinols. F. MAUTHNER. Univ. Budapest. *J. prakt. Chem.* 119, 311-4(1928).—*o*- $\text{C}_6\text{H}_4(\text{OMe})_2$ (20 g.), 30 g. AcCl , 40 g. AlCl_3 and 80 cc CS_2 give 19 g. of a product consisting of 8 g. of 2,4,5- $\text{Ac}_2(\text{MeO})\text{C}_6\text{H}_3\text{OH}$, m. $121-2^\circ$, and 5 g. of 2,4,5- $\text{Ac}_2(\text{MeO})\text{C}_6\text{H}_3\text{OMe}$, m. $171-2^\circ$. *o*- $\text{C}_6\text{H}_4(\text{OEt})_2$ (20 g.), 30 g. AcCl , 35 g. AlCl_3 and 80 cc. CS_2 give 16.4 g. 2,4,5- $\text{Ac}_2(\text{EtO})\text{C}_6\text{H}_3\text{OH}$, m. 109° .

C. J. WEST

Catalytic condensation of acetylene with phenols. II. Resorcinol. S. AQUINAS FLOOD AND J. A. NEUWLAND. Univ. of Notre Dame. *J. Am. Chem. Soc.* 50, 2566-73 (1928); cf. C. A. 18, 1995.—Condensation of *m*- $\text{C}_6\text{H}_4(\text{OH})_2$ and C_2H_2 in MeOH with a Hg catalyst gives 83% of vinylresorcinol (I), 2,4-($\text{HO})_2\text{C}_6\text{H}_3\text{CH}=\text{CH}_2$, cryst. with 1 mol. MeOH, which gradually polymerizes on standing, and 10% of dihydroxymethylxanthene. Attempts to prep. directly the Me ethers have been unsuccessful. *m*- $\text{C}_6\text{H}_4(\text{OMe})_2$ condenses with C_2H_2 to give the *di*-Me ether of I, pale yellow, b. 235° (decompn.). Reduction of I gives ethylresorcinol. Ac_2O gives the acetate, m. $285-6^\circ$. The same products are obtained in the condensation of AcH under similar conditions. C. J. W.

Aromatic allyl and propenyl compounds. I. Safrole and isosafrole. H. I. WATERMAN AND R. PRIESTER. Techn. Univ., Delft. *Rec. trav. chim.* 47, 849-60(1928).—

Two com. samples of safrole were examd., both having a yellow color. Fractionation in a cathodic vacuum did not give pure safrole, the 4 fractions obtained showing the setting points 10.30° , 10.60° , 10.78° and 10.69° . Thus the safrole was purified by means of the $\text{Hg}(\text{OAc})_2$ addn. compd. (Manchot, *Ann.* **421**, 316(1920); cf. *C. A.* **14**, 3416), the pure product showing the setting point 11.0° , n 1.5331, n 1.5383, n 1.5518, n 1.5638 for C, D, F and G at 20° , and d_4^{20} 1.100. Isosafrole was purified by means of the addn. compd. with picric acid (Hoering and Baum, *C. A.* **3**, 2946), b. p. in a cathodic vacuum 46.8° , d_4^{20} 1.122, n 1.5708, n 1.5782, n 1.5986, n 1.6183 for C, D, F and G at 20° . According to Nagai (*C. A.* **16**, 418) this β -isosafrole is the *trans*-compd. Both with safrole and isosafrole the equil. const. in the reaction with I were detd: $K = [\text{concn. of the I addn. compd.}] / [\text{final concn. of the iodine}] \times [\text{final concn. of the unsatd. compd.}]$. When light is excluded, for safrole $K_0 = 2$ and $K_{25} = 1$ in CCl_4 and after a reaction time of 120 hrs. while in diffuse daylight after 32 hours $K_0 = 260$ was found. For isosafrole after 32 hrs. in diffuse daylight $K_0 = 20$. Partly the addn. of I is due to impurities, pure safrole and pure isosafrole hardly taking up any I at 0° , provided light be excluded. If, however, I has been taken up in diffuse daylight, it is not split off afterwards when the solns. are kept in the dark. The different behavior of safrole and isosafrole towards I solns. in CCl_4 makes it possible to analyze mixts. of safrole and isosafrole by means of the equil. const. which is found after a reaction time of 8 hrs. in diffuse daylight, provided the equil. const. of safrole-isosafrole mixts. of known concn. be detd. at the same time. Solns. of safrole and isosafrole in CCl_4 brought together in diffuse daylight with aq. KI liberate I, the safrole soln. being more active than that of isosafrole.

C. F. VAN DUIN

Color and constitution. III. The influence of the methylthiol, methoxy and chlorine groups on the colors of the nitrobenzaldehyde phenylhydrazones. HERBERT H. HODGSON AND FREDERICK WM. HANDLEY. Tech. College, Huddersfield. *J. Chem. Soc.* **1928**, 1882-6; cf. *C. A.* **22**, 1340.—Trustworthy conclusions could not be deduced from the colors of the solid hydrazones because of their wide variation with the mode of crystn., but equimol. alc. solns. exhibited a well-defined order. The absorption spectra curves confirm the results of the visual observations and the relative order of the effects of the substituent is the same whether these are present in the aldehyde or the hydrazone residue and is independent of the position of the NO_2 group: *o*-Cl (lemon-yellow) *o*-SMc, *p*-Cl, H, *o*-OMe, *p*-SMe (increasing depth), *p*-OMe (deep reddish orange). The influence of the substituents is, in general, less marked than in the case of the azo dyes. *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{CH}=\text{NNHPh}$ crystallizes from glacial AcOH in yellow needles, m. 194° , which slowly become pale orange without change of m. p. Exposure to ultraviolet light for some hrs. or to sunlight for some weeks produced no change. Addn. of H_2O to a glacial AcOH soln. ppts. a yellow variety changing in a few sec. into the red form. Reduction of 4-MeSC₆H₄N₂Cl with SnCl_2 and HCl gives the *HCl* salt, plates, of 4-methylthiolphenylhydrazine, m. 60° ; 2-methylthiolhydrazine, m. 40° . In the following the color on addn. of EtOH-KOH and the change on heating are given immediately following the m. p. Derivs. of benzaldehyde-*o*-nitrophenylhydrazones: *o*-Cl, orange, m. 178° , deep blue, unchanged; *p*-Cl, scarlet, m. $203-4^\circ$, blue, unchanged; *o*-MeO, bright red, m. $176-7^\circ$, violet-blue, unchanged; *p*-MeO, scarlet, m. 204° , blue-violet, unchanged; *p*-MeS, scarlet, m. $225-6^\circ$, blue-violet, unchanged. Derivs. of benzaldehyde *m*-nitrophenylhydrazones: *o*-Cl, pale orange, m. 171° , brownish yellow, deeper; *p*-Cl, orange-red, m. 172° , brownish yellow, deeper; *o*-MeO, reddish orange, m. 176° , orange, brownish orange; *p*-MeO, orange-yellow, m. 156° , brownish yellow, deeper; *p*-MeS, old-gold, m. 146° , brownish yellow, deeper. Derivs. of benzaldehyde *p*-nitrophenylhydrazones: *p*-Cl, deep orange, m. 224° , violet, deeper; *o*-MeO, brick-red, m. 204.5° , violet, deeper; *p*-MeS, deep orange, m. 183° (turns yellow at $140-5^\circ$), violet, deeper. Derivs. of benzaldehyde *o*-methylthiophenylhydrazones: *o*-NO₂, deep orange, m. $87-8^\circ$, yellowish green, olive-green; *m*-NO₂, orange, m. 118° , yellow, brownish yellow; *p*-NO₂, red, m. 147° , olive-green, bluish green. Benzaldehyde *p*-methylthiolphenylhydrazones, m. 93° , yellow, deeper; *o*-NO₂ deriv., brownish red, m. 204° , olive-green, bluer; *m*-NO₂, orange-red, m. 152° , brown, deeper; *p*-NO₂, scarlet, m. 179° , olive-green, bluish green. *p*-Methylthiolbenzaldehyde phenylhydrazones, m. 138° , yellow, deeper. Absorption curves are given for some of these compds.

C. J. WEST

Sulfur-containing derivatives of acetophenone. EUGEN RIESZ AND WALTER FRANKFURTER. Univ. Wien. *Monatsh.* **50**, 68-75(1928).—PhAc (5 g.) and 50 g. ClSO_3H , heated 1 hr. at 110° , give acetophenone-3,5-disulfonyl chloride, m. $195-6^\circ$; anilide, yellow, m. $195-6^\circ$ (decompn.). Reduction with Zn and HCl in EtOH gives 3,5-dimercaptoacetophenone, m. 128° (*Pb* salt, orange-red); oxidation with air in alk.

soln. gives no trace of a thioindigo dye. $p\text{-H}_2\text{NC}_6\text{H}_4\text{Ac}$, through the diazo reaction with alk. xanthate soln. and heating the resulting product, gives $p\text{-HSC}_6\text{H}_4\text{Ac}$, characterized by the formation of $p\text{-acetophenylthioglycolic acid}$, m. 155–6°; with ClSO_3H this gives a red dye. Oxidation of $p\text{-HSC}_6\text{H}_4\text{Ac}$ and the resulting Na salt treated with ClSO_3H gives an *acetophenonedisulfonyl chloride*, m. 210° (decompn.), (probably the 2,4-deriv.); *anilide*, yellow, m. 235° (decompn.); reduction gives 2,4-dimercaptoacetophenone, m. 215° (Pb salt, orange-red); this compd. also does not give a thioindigo dye.

C. J. WEST

New bromine substitution products of vanillin and some of their derivatives. L. CHAS. RAIFFORD AND W. C. STOESEER. State Univ. of Iowa. *J. Am. Chem. Soc.* **50**, 2556–63 (1928); cf. *C. A.* **21**, 1803, 2258.—6-Bromovanillin oxime and Ac_2O give 98% of the *Ac deriv.*, m. 149–51°. Acetyl-6-bromovanillin gives 89% of the *oxime*, m. 150–2°, whose *Ac deriv.*, m. 153–4°. 3-Methoxy-4-acetoxy-6-bromobenzonitrile, m. 148–9°, by boiling the *Ac deriv.* with Ac_2O for 1 hr. Refluxing with 6 N KOH for 3.5 hrs. gives 98% of 6-bromovanillic acid, m. 190–1°. Nitration of acetylvanillin gives a mixt. of the 2-nitro deriv., m. 136°, and the 6-nitro deriv., yellow, m. 212°. Acetyl-2-nitro-5-bromovanillin, m. 128°. Hydrolysis of this, or bromination of the above 2- NO_2 deriv., gives 2-nitro-5-bromovanillin, m. 150–1°; reduction with FeSO_4 and NH_4OH gives the 2-amino deriv., tan colored, m. 139–40°, which, through the diazo reaction with HBr, gives 2,5-dibromovanillin, m. 189°; *Ac deriv.*, m. 68–70°; $p\text{-nitrophenylhydrazine}$, yellow, m. 249°; *semicarbazone*, m. 233–4°; *bisbenzidine deriv.*, bright orange, m. above 350°; *oxime*, m. 154–5°; *oxime acetate*, m. 184–5°; *acetyloxime acetate*, m. 137–9°; *acetoxy-nitrile*, m. 89–90°; 2,5-dibromovanillic acid, m. 179–80°; 2,5-dibromo-3-methoxy-4-acetoxybenzal diacetate, m. 157–8°, hydrolysis gives the original vanillin. 2-Nitro-6-bromovanillin, cream colored, m. 168–70°; 2-amino deriv., yellow, m. 217–8°; 2,6-dibromovanillin, m. 155–6°; *oxime*, m. 144–5°; $p\text{-bromophenylhydrazine}$, flesh colored, m. 168–70°; *semicarbazone*, m. 216–7°; *bisbenzidine deriv.*, yellowish brown, m. 238–9°. Further bromination gives 2,5,6-tribromovanillin, m. 177–8°; *oxime*, m. 192°; $p\text{-bromophenylhydrazine}$, m. 169–70°; *semicarbazone*, m. 222–3°; *bisbenzidine deriv.*, brown, m. above 330°.

C. J. WEST

Condensation of heptanal with aromatic aldehydes. B. N. RUTOVSKII AND A. I. KOROLEV. Chem.-Pharm. Forschungskinst. Moskau. *J. prakt. Chem.* **119**, 272–4 (1928).— BzH (10.6 g.) and 11.4 g. $\text{C}_6\text{H}_{13}\text{CHO}$ in 100 cc. EtOH and 500 cc. H_2O , condensed by 7 cc. of 10% NaOH, give $\alpha\text{-amyl-}\beta\text{-phenylacrolein}$, pale yellow, b_D^{20} 174–5°, d_4^{20} 0.97108, n_D^{20} 1.5381; *oxime*, m. 72–5–3°; *semicarbazone*, m. 117.5–8°. With $\text{BzNH-CH}_2\text{CO}_2\text{H}$ it gives 4-[benzylidene-2-heptylidene]-2-phenyl-5-oxazolone, golden yellow, m. 97–8°.

C. J. WEST

Thermal decomposition of thiobenzanilide. ARTHUR WM. CHAPMAN. Univ. of Sheffield. *J. Chem. Soc.* **1928**, 1894–7.—Upon heating PhCSNHPh at 270–310° the following products were obtained: 38–58% of 1-phenylbenzothiazole (I), 11–9% of *sym*-diphenylbenzenyl amidine (II), stilbene, tetraphenylthiophene (III) and 37–40% H_2S . The following series of reactions would then represent the decompn.: $\text{PhCSNHPh} \rightarrow \text{I} + 2\text{H}$; $2\text{H} + \text{PhCSNHPh} \rightarrow \text{PhNH}_2 + \text{PhCHS}$; $\text{PhNH}_2 + \text{PhCSNHPh} \rightarrow \text{II} + \text{H}_2\text{S}$; $\text{PhCHS} \rightarrow \text{PhCH-CHPh} + \text{III} + \text{H}_2\text{S}$.

C. J. WEST

Esterification velocities of the nitrobenzoic acids in ethyleneglycol and of the naphthoic acids in glycerol. ANTON KAILAN AND EMIL KRAKAUER. Univ. Wien. *Monatsh.* **49**, 347–84 (1928).—The monomol. esterification constns. of the $\text{O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ in glycol and of the $\text{C}_{10}\text{H}_7\text{CO}_2\text{H}$ in $\text{C}_2\text{H}_5(\text{OH})_2$, catalyzed by HCl, have been detd. at 25° and expressed by formulas as functions of the H_2O (w) and HCl concn. (c) of the medium. The constns. increase in anhyd. $\text{C}_2\text{H}_5(\text{OH})_2$ and $\text{C}_2\text{H}_4(\text{OH})_2$ and in H_2O -contg. $\text{C}_2\text{H}_5(\text{OH})_2$ in proportion to the HCl concn., in H_2O -contg. $\text{C}_2\text{H}_4(\text{OH})_2$ more rapidly than the HCl concn. For $c = 1/6$ and $w = 0.065$, the relation of the monomol. constns. of BzOH to those of *o*-, *m*- and *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ and the α - and β - $\text{C}_{10}\text{H}_7\text{CO}_2\text{H}$ in EtOH is: 1:0.054:0.57:0.70:0.39:1.00; in glycol, 1:0.038:0.69:0.79; in glycerol, 1:0.068:0.63:0.80:0.61:0.93. The steric hindrance through *o*-substitution is thus smaller in glycerol but greater in glycol than in EtOH. With a small H_2O content the esterification constns. in both media are smaller than in EtOH, but in large concns. of H_2O , the constns. are larger. Under the exptl. conditions, practically complete esterification occurs, so that resapon. does not enter into consideration. The esterification of the $\text{C}_{10}\text{H}_7\text{CO}_2\text{H}$ in $\text{C}_2\text{H}_5(\text{OH})_2$ is also studied without a catalyst.

C. J. WEST

Esterification velocities of monoaminobenzoic acids and 1- and 2-pyridinecarboxylic acids in glycol and glycerol. ANTON KAILAN AND YEHIA M. DIAB. Univ. Wien. *Monatsh.* **49**, 316–46 (1928).—The esterification velocities of the $\text{H}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ and of

1- and 2- $C_6H_4NCO_2H$ at 25° with HCl as the catalyst were measured in anhyd. and H_2O -contg. $C_3H_7(OH)_2$ and in anhyd. $C_3H_7(OH)_3$, and for *m*- and *p*- $H_2NC_6H_4CO_2H$ and the 2- $C_6H_4NCO_2H$ in H_2O -contg. $C_3H_7(OH)_3$. The dependence of the monomol. velocity const. upon the H_2O content (*w*) of medium and the excess of the concn. of the HCl over that of the org. acid or its ester (*C'*) is expressed for the last 3-named acids by means of formulas. These velocity const. increase throughout, both in anhyd. and H_2O -contg. glycol and glycerol more quickly not only than the concn. of the total HCl but also than that of the "free" HCl. For $C' = 1/3$ and $w = 0.03$, the velocity const. of the *m*- and *p*- $H_2NC_6H_4CO_2H$ and of nicotinic acid in EtOH is 20-30%, for *o*- $H_2NC_6H_4CO_2H$ 70% and for picolinic acid 130% greater than in glycol; for $w = 0.7$, it is 35-50% smaller for the 1st 3 acids. In glycol the const. for *o*- $H_2NC_6H_4CO_2H$ and the $C_6H_4NCO_2H$ are smaller than in glycerol, but are greater for the remaining acids. The steric action of the NH_2 group in the *o*-position is greater in glycol but smaller in glycerol than in EtOH. Under similar conditions, the esterification velocity const. of nicotinic acid in glycol and glycerol is 4 times, in EtOH only about 2 times greater than that of picolinic acid.

C. J. WEST

Wandering of the alkyl groups in the Fries transformation. K. v. AUWERS AND W. MAUSS. Univ. Marburg. *Ann.* 460, 240-77(1928); cf. C. A. 20, 2154.—In continuing the earlier work, the Fries' transformation has been effected with a no. of other polyalkylphenyl acetates, by the methods of rapid or of slow heating with $AlCl_3$. In order to det. whether wandering of alkyl has occurred during the transformation, the Ac group is removed from the resulting hydroxyacetophenone and the new phenol identified. P_2O_5 used formerly for this removal is often less effective than boiling glacial AcOH-HBr. In general *o*- and *p*-hydroxyacetophenones are separable by steam distn.; the *m*-derivs. must be isolated by special methods. An alkyl group in the *m*-position to the AcO group favors the formation of *o*-hydroxyacetophenones. Two *m*-groups produce an even greater tendency in the same direction. Thus, 3,5-Me₂C₆H₃OAc and 3,5-Et₂C₆H₃OAc give no trace of a *p*-deriv. When 1 *m*-alkyl group is present, the Fries' change gives a little *p*-compd. A 2nd Me group in the *o*-position does not weaken the effect of the *m*-group in this respect. Ph acetates with a free *o*-position give a Fries' change only if 1 alkyl group is in position 2 and a 2nd in position 5. The Et group is much more readily displaced than Me. When Et groups are present in both *o*- and *p*-positions, the *o*-group is eliminated, the displaced Et group wandering into the *p*-position to that it originally occupied. Other new facts which show the greater valency requirement of Et over Me are the abnormal Gattermann aldehyde and Friedel-Crafts' ketone syntheses recorded with 2,4-MeEtC₆H₃OMe and 5,2,4-MeEt₂C₆H₃OMe. 2,4-Dimethyl-6-ethylphenyl acetate, b. 242°, in the Fries transformation, gives 70% of a mixt. of 2-hydroxy-3,5-dimethyl-4-ethylacetophenone (I), m. 52-3°, b₁₁ 153-5° (oxime, m. 157-5-8.5°; *p*-nitrophenylhydrazone, yellow, m. 212-4°; semicarbazone, pale yellow, m. 235-6°), and 2-hydroxy-4,5-dimethyl-3-ethylacetophenone (II) (semicarbazone, m. 219-21°; oxime, m. 115-6°; *p*-nitrophenylhydrazone, reddish yellow, m. 179-83°). I, upon reduction, gives 72% of 2,4-dimethyl-3,6-diethylphenol, m. 59.5-60.5°, b. 250-2°; Me ether, b. 218-20° which gives with AcCl and $AlCl_3$ only 2-hydroxy-5,6-dimethyl-3-ethylacetophenone, yellow, b₁₁ 143-5° (oxime, m. 153-4°; *p*-nitrophenylhydrazone, yellow, m. 251-3°); reduction gives 3,4-dimethyl-2,6-diethylphenol, b. 246-8°, m. 47-8°. 3-*o*-Xylyl acetate, b. 226-8°, with $AlCl_3$ and AcCl, gives 60% of 2-hydroxy-3,4-dimethylacetophenone, light yellow oil volatile with steam, b₁₂ 122-4° (FeCl₃ gives a deep violet-blue color) (*p*-nitrophenylhydrazone, red, m. 216-8°), which is reduced to 2,3-dimethyl-6-ethylphenol, m. 53-4°; its Me ether, b. 216-8°, with $AlCl_3$ and AcCl gives 4-methoxy-2,3-dimethyl-5-ethylacetophenone, volatile in steam, b₁₂ 138-40°, reduced to 2,3-dimethyl-4,6-diethylanisole, b. 234-6°, which is demethylated to 2,3-dimethyl-4,6-diethylphenol, b. 244-6°. 3,4-Dimethyl-6-ethylphenyl acetate, b. 247-9°, is converted by the Fries' transformation into a mixt. of hydroxyacetophenones, b₁₂ 145-7°, which cannot be sepd. by distn. Reduction gives as the only product 4,5,2,6-Me₂Et₂C₆H₃OH, m. 47-8°; fractionation of the *p*-nitrophenylhydrazones shows the presence of 2,3,5,6- and 2,3,4,5-HOEtMe₂C₆HOAc. 2,4-Dimethyl-6-ethylanisole, b. 210-1°, slowly reacts with AcCl and $AlCl_3$ to give some 6,2,4-EMe₂C₆H₃OH and, as the main product, 3-hydroxy-2,6-dimethyl-4-ethylacetophenone, b₁₁ 178-82°. 2,4-Dimethyl-5-ethylphenol, b. 242-4°, m. 39-40°; the acetate, b. 254-6°, is transformed (Fries) mainly into 4,3,5,2-EtMe₂(HO)C₆HOAc (converted in poor yield by H_3PO_4 into 2,4-dimethyl-3-ethylphenol, m. 70-1°), and some 2,3,5,6-EtMe₂(HO)C₆HOAc, isolated only as the impure oxime, m. 120-5°. 2,4-MeEtC₆H₃OMe, HCN, HCl and $AlCl_3$ give mainly 3,4-Me(MeO)C₆H₃CHO, the by-product being 2-hydroxy-3-methyl-5-ethylbenzaldehyde, a yellow oil, b₁₂ 120-2° (*p*-nitrophenylhydrazone, red, m. 167-9°). 2-*m*-Xylyl acetate, b. 214-6°, with $AlCl_3$,

slowly heated to 120°, gives mainly 4-hydroxy-2,6-dimethylacetophenone, m. 150–1°, which is reduced to 2,6-dimethyl-4-ethylphenol, b. 228–30°, m. 36–7°; the acetate, b. 245–7°, is converted (Fries) mainly into 4,3,5-HOMe₃C₆H₂Ac and some 2,4,3,5-HOEt-Me₃C₆H₂Ac. 4-Methyl-2,6-diethylphenol, b. 229–30°, m. 48–8.5°; benzoate, m. 103–3.5°; acetate, pale yellow oil, b. 242–3°. In the Fries' transformation the latter gives 60% of 2-hydroxy-5-methyl-3,4-diethylacetophenone, a yellow oil, b₁₂ 136–7° (oxime, m. 108–9°; semicarbazone, m. 228–9°; *p*-nitrophenylhydrazone, reddish yellow, m. 254–6°); reduction gives 3-methyl-2,3,6-triethylphenol, pale yellow oil, b. 242–4°. 3-Methyl-6-ethyl-anisole, b. 200°, with AcCl and AlCl₃ gives a very little 2-hydroxy-6-methyl-3-ethylphenol, b₁₂ 137–8°, and mainly 4-methoxy-2-methyl-5-ethylacetophenone, b₁₂ 139–40°, m. 29–30°; reduction gives 3-methyl-4,6-diethylanisole, b. 222–4° (75% yield); 3-methyl-4,6-diethylphenol, b. 247–9°; its acetate, b. 258–60°; phenylurethan, m. 109–10°. The acetate under Fries' conditions gives a mixt. of 5,3,4,2-MeEt₂(HO)C₆H₂Ac and 6,3,5,2-EtMe₂(HO)C₆H₂Ac(?). The anisole with AcCl and AlCl₃ gives a mixt. of 2-hydroxy-4-methyl-5-ethylacetophenone, m. 94–5°, and 2-methoxy-6-methyl-3,5-diethylacetophenone, pale yellow oil, b₁₁ 146–8°; reduction gives 3-methyl-2,4,6-triethylphenol, b. 252–4°; AlCl₃ gives 3-methyl-2,4,6-triethylphenol, b. 256–8°; the Na salt is sparingly sol. 3-Methyl-4-ethylphenol, b. 228–30°; the acetate, b. 239–40°, in the Fries' transformation gives 70% of 4,5,2-MeEt(HO)C₆H₂Ac, m. 94–5°. 2,4-MeEtC₆H₃OH yields a benzoate, m. 47–8°, and an acetate, b. 238–40°. With AlCl₃ the latter gives 77% of 2-hydroxy-3-methyl-5-ethylacetophenone, yellow oil, b₁₁ 129–31° (*p*-nitrophenylhydrazone, red, m. 196–8°); reduction gives 65% of 2-methyl-4,6-diethylphenol, b. 234–6°; the acetate, b. 250–2°, with AlCl₃ gives 2-hydroxy-3-methyl-4,5-diethylacetophenone, m. 50–1° (oxime, m. 125–6°; *p*-nitrophenylhydrazone, red, m. 187–90°); reduction gives 2-methyl-3,4,6-triethylphenol, m. 28–9°, b. 252°. Rearrangement of *p*-EtC₆H₄OAc with AlCl₃ for 6.5 hrs gives 70% of 2-hydroxy-5-ethylacetophenone, b₁₂ 119–21° (oxime, m. 118–9°); reduction gives 80% of 2,4-diethylphenol, b. 228–30°; phenylurethan, m. 96–9°; acetate, b. 242–4°; the latter with AlCl₃ gives 67% of 2-hydroxy-3,5-diethylacetophenone, yellow oil, b₁₂ 138–40° (*p*-nitrophenylhydrazone, reddish yellow, m. 136–8°). Reduction gives 2,4,6-triethylphenol, b. 244–6°; the acetate, b. 260–2°, with AlCl₃ gives 65% of 2-hydroxy-3,4,5-triethylacetophenone, yellow oil, b₁₂ 153–5°. 2,6-Me₂C₆H₃OAc when heated rapidly with AlCl₃ at 130–40° gives only 3,5,4-Me₂(HO)C₆H₂Ac, while 2-methyl-6-ethylphenyl acetate, b. 220–2°, gives some 2-hydroxy-3-methyl-5-ethylacetophenone, b₁₂ 130–2° (*p*-nitrophenylhydrazone, m. 191–5°), but chiefly 4-hydroxy-3-methyl-5-ethylacetophenone, m. 95.5–6.5°. Fries' conditions convert *o*-EtC₆H₄OAc into 2-hydroxy-3-ethylacetophenone, b. 213° (*p*-nitrophenylhydrazone, m. 213–7°), reduced to 2,6-Et₂C₆H₃OH, the acetate, b. 238–40°, of which when heated rapidly under Fries' conditions gives a little *o*-HO ketone but mainly 4-hydroxy-3,5-diethylacetophenone, m. 92–2.5°. 3,5-Diethylphenyl acetate, b. 250–1°, is converted by AlCl₃ into 2-hydroxy-4,6-diethylacetophenone, b₁₂ 140°.

C. J. WEST

Different methods of preparation of phenylethylmalonic dimethyl ester. THOMAS WM. RAY. *Abstracts of Theses, Univ. Chicago, Science Series* 4, 151–6 (1925–6) (publ. May, 1928); cf. C. A. 12, 908.—An attempt to prep. PhEtC(CO₂Me)₂ (I) through following steps: PhPr (II), PhCBr₂Et (III), PhC(CN)₂Et, failed, because bromination of II led to an unsatd. compd., which probably is PhCH·CHMe, instead of to III. In another expt., the starting material was PhCOEt, which by means of HCl and HCN was to be converted into EtCPhC(CO₂H) (IV). IV with AgCN should give EtCPh(CN)CO₂H, which with HCl and MeOH would give I. Instead of IV, the reaction gave methyl-atropic acid, PhC(·CHMe)CO₂H, m. 134–6°. In a 3rd attempt, PhCH₂CN was treated with NaNH₂ and EtI giving EtCHPhCN (V). Hydrolysis of V gave EtCHPhCO₂H, which was converted into EtCPhBrCOBr (VI) by means of PhBr₂ and Br. VI and MeOH gave Me α -phenyl- α -bromobutyrate (VII), unstable, decompd 95–100° at 2 mm. VII and KCN should give EtCPh(CN)CO₂Me (VIII), which with HCl and MeOH would give I. The reaction of VII with KCN gave either no VIII at all or only a very small quantity. Me α -phenyl- α -cyanobutyrate (from V by reaction with NaNH₂ and ClCO₂Me), b_{0.1} 120–30°. The yield was too small to render its transformation into I practical. Et α -phenyl- α -cyanobutyrate, b_{0.2} 100–40°.

G. SCHWOCH

Addition of halogens to unsaturated acids and esters. I. The addition of equimolecular mixt. of bromine and chlorine to cinnamic acid and its derivs. in non-hydroxylic solvents. NORMAN WM. HANSON AND THOMAS C. JAMES. Univ. College of Wales, Aberystwyth. *J. Chem. Soc.* 1928, 1955–60.—An equimol. mixt. of Br and Cl, in CCl₄, reacts additively with PhCH:CHCO₂H as BrCl, where such a compd. existent, the product of addn. being the 2 stereoisomeric PhCHClCHBrCO₂H. Such a BrCl soln. has been shown kinetically to react at a far more rapid rate with PhCH:CHCO₂H and some

of its derivs. than Br soln. itself. These phenomena appear to be readily explicable along the lines of modern polarity theories.

C. J. WEST

Preparation of nitrososalicylic acid and of aminosalicic acid. V. G. GULINOV. *J. Chem. Ind. (Moscow)* 4, 909-10(1927); 5, 225-8(1928).—Two groups of methods have been proposed for the prepn. of aminosalicic acid, viz. (1) through the nitro compd. and (2) from azo derivs. of salicylic acid. A method of prepg. aminosalicic acid from the NO compd. has hitherto not been proposed, although similar methods of prepn. of other aminophenols are widely used industrially. G. investigated the possibility of applying this method to aminosalicic acid and proceeded to prep. first *nitrososalicylic acid*. According to the Ger. pat. 25,469 (1883) the latter may be prepared by means of nitrites of heavy metals (cf. also *Ber.* 18, 705); G. modified this method as follows: 25-35 g. CuSO_4 and 7 g. NaNO_2 in 150-cc. water was poured in a thin stream into 16 g. Na salicylate in 450-cc. water. If the former soln. is introduced too rapidly Na salicylate is salted out and the operation is delayed considerably. CuSO_4 is taken in excess to insure the complete sepn. of the Cu-nitroso salt formed. The mixt. is left standing at room temp. for 24 hrs., then the ppt. of Cu-nitroso salt is filtered and the filtrate, after standing 9-10 days more, ppts. an addnl. quantity of the same substance, $\text{C}_6\text{H}_3\text{CO}_2\text{OCuNO}$. To avoid long standing of the filtrate the nitroso salt may be salted out by NaCl . The yield of the nitroso salt is 93-7% of the theoretical. To obtain free nitrososalicylic acid, 4,2-ON(HO) $\text{C}_6\text{H}_3\text{CO}_2\text{H}$, the freshly filtered ppt is treated with 5% NaOH not above 40-5°, whereupon the NO compd. dissolves as the Na salt; the latter, after sepg. the ppt. of Cu(OH)_2 , gives free nitrososalicylic acid by decomn. with HCl . There is no difficulty in obtaining *aminosalicylic acid* by reducing either the free NO compd. or its Na salt by Sn and HCl , or by $\text{Na}_2\text{S}_2\text{O}_4$. Aminosalicic acid can also be prepd. by passing through the NO compd. without isolating the latter, conforming to the Ger. pat. 48,491 (1889), which was modified by G. as follows. Concd. AcOH is added drop by drop to strongly acid reaction to a soln. of 16 g. Na salicylate and 7.5 g. NaNO_2 in 800 cc. water. After 20 hrs the NO compd. formed is reduced by 200 g. of $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$ crystals. After standing 3 hrs. the soln. is heated to 70-80° for the removal of SO_2 . The yield of aminosalicic acid is 76% of the theoretical. Friedlander (*Fortschritte* 2, 222) expressed doubt whether nitrososalicylic acid is actually formed as an intermediate product in this process.

BERNARD NELSON

Synthesis of a new gallic aldehyde. F. MAUTHNER. Univ. Budapest. *J. prakt. Chem.* 119, 306-10(1928).—4-Methylgallic acid and ClCO_2Me in N NaOH give 3,5-dicarboximethoxy-4-methylgallic acid, m. 120-1°; the chloride, m. 58-9°; reduction with Pd- BaSO_4 and H in PhMe at 110° and sapon. give 3,5-dihydroxy-4-methoxybenzaldehyde, m. 139-40°; *p*-nitrophenylhydrazone, red, m. 222-3°.

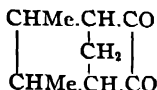

C. J. WEST

6-Aldehydocoumarin and dyes derived from it. RAJENDRANATH SEN and DUH-AHARAN CHAKRAVARTY. Presidency College. *J. Am. Chem. Soc.* 50, 2428-36(1928).—Coumarin (16 g.) in 27 g. NaOH and 40 cc. H_2O , heated on the H_2O bath and treated during 8-9 hrs. with 20 cc. CHCl_3 , gives 3.5 g. 6-aldehydocoumarin (I), pale yellow, decmps. 174-5°, the decomp. product, m. 205-7°; phenylhydrazone, yellow, m. 205-7°. I in NaOH condenses with Me_2CO , giving *dicaumaralacetone*, yellow, m. 159°; *coumaralacetophenone*, m. above 250°. I undergoes the benzoin condensation, giving *coumaroin*, reddish yellow, m. 178-80°. I and *p*- $\text{MeC}_6\text{H}_4\text{NH}_2$ in EtOH-AcOH give *coumaral-p-toluidine*, m. 145-7°. Other derivs. prepd. were: *β*-naphthylamine, m. 173°, pale yellow; *p*-nitroaniline, yellow, m. above 250°; aminoazobenzene, red-yellow, m. 169°; *dicaumaral-p-phenylenediamine*, brown, m. above 250°; *m-phenylenediamine*, brown, m. above 250°; *o-phenylenediamine*, yellow, m. above 250°; *safranin*, red-violet; *tricoumaralrosaniline*, red-violet, m. 142°; *coumaralhenzidine*, yellow, m. above 250°; *chrysoidine*, orange, m. 210-2°; the behavior with silk and wool is given. I and Ph-NMe_2 , heated on the H_2O bath for 30 hrs. with the addn. of 10 cc. HCl , give *tetramethyldiaminodiphenylcoumarylmethane*, m. 220° (90% yield); oxidation with PbO_2 gives the *carbinol* (coumaral green), the HCl salt of which is a deep bluish green, producing a bluish green shade on silk, wool and tanned cotton. I (1 mol.) and 4 mols. *m*- $\text{C}_6\text{H}_4(\text{OH})_2$, heated with concd. H_2SO_4 4-5 hrs. at 120-30°, give *tetraresorcinolcoumarin*, red, with a red-green fluorescence in alk. or EtOH solns., softens 225° (80% yield); *K* salt; *hexa-Br deriv.*, deep red. *Tetrahydroquinone deriv.*, red-violet; *tetra-K salt*; *tetra-Br deriv.*, yellow. *Tetra-β-naphthol deriv.*, the α -deriv. was also prepd. *Tetragallic acid deriv.*, black. *Coumaralrhodamine*, blue-violet.

C. J. WEST

Santenonequinone and a general method for the preparation of diketones. J. PALMÉN. *Finska Kemistamfundets Medd.* 36, 11-21(1927).—In the prepn. of isonitrosocamphor, NaNH_2 and benzene were substituted for Na and ether. Treatment with HCHO and HCl then yields a diketone, the method being convenient for diketones

having an unsubstituted CH_2 group next to the CO group. In this way were obtained isonitrososantenone and an oil, possibly a geometrical isomeride. Thence were obtained santenonequinone hydrate, m. $137-8^\circ$, and santenonequinone (annexed formula),

m. $84-5^\circ$ [disemicarbazone, m. 238° (uncor.)]. The dioxime, $\text{C}_9\text{H}_{14}\text{O}_2\text{N}_2$, m. $144-5^\circ$. Oxidation of the quinone with 2% KMnO_4 yields santenic acid, $\text{C}_9\text{H}_{14}\text{O}_4$. B. C. A.

Syntheses in the diphenyl series. LEONARD F. HINKEL and DONALD H. HEY. Univ. College, Swansea. *J. Chem. Soc.* 1928, 1838-40.—The view (C. A. 22, 2927) that 4,5,5-tribromo-1-phenylcyclohexan-3-one decomps. into 5,3-Fr(HO) $\text{C}_6\text{H}_4\text{Ph}$ (I) and 4,5,3-Br₂(HO) $\text{C}_6\text{H}_4\text{Ph}$ (II) is confirmed by their syntheses. 5-Bromo-3-nitro-4-aminodiphenyl, deep orange, m. 100° (Ac deriv., m. 95°); the diazo soln. with CuBr gives 4,5-dibromo-3-nitrodiphenyl, pale yellow, m. 125° ; reduction and acetylation give 4,5-*a*-bromo-3-acetaminodiphenyl, m. 177° ; hydrolysis, followed by the diazo reaction, gives II. 5-Bromo-3-aminodiphenyl, light brown, m. 88° ; Ac deriv., m. 140° ; the diazo soln., heated to boiling, gave a dark oil, identified as the Bz deriv. of I, m. 108° . 5,4'-Dibromo-3,4-diaminodiphenyl, m. 120° ; di-Bz deriv., m. 278° . C. J. WEST

Molecular configuration of polynuclear aromatic compounds. VII. 5,5'-Dichlorodiphenyl-3,3'-dicarboxylic acid. FRED B. MCALISTER and JAMES KENNER. Univ. of Sydney. *J. Chem. Soc.* 1928, 1913-6; cf. C. A. 20, 1801.—5,3- $\text{O}_2\text{N}(\text{H}_2\text{N})\text{C}_6\text{H}_3\text{CO}_2\text{H}$ and $\text{K}_2\text{S}_2\text{O}_8$, added to fuming HNO_3 at -2° and after 2 hrs., the dild. soln. treated with KI, gives 5-iodo-3-nitrobenzoic acid, m. $166-7^\circ$; Et ester, m. $59-60^\circ$. A di-Ph deriv. could not be prep'd. from the ester. 3-Bromo-5-iodotoluene, b_p , 150° , m. 23° . 5-Bromo-aceto-*m*-toluidide, m. $171-2^\circ$, on oxidation with KMnO_4 , gives 3-bromo-5-acetamidobenzoic acid, m. $279-81^\circ$; concd. HCl gives 5-bromo-3-aminobenzoic acid, m. $220-2^\circ$; 3-bromo-5-iodobenzoic acid, m. $209-11^\circ$; Me ester, orange, m. $59-61^\circ$. 3-Chloro-5-iodotoluene, b_p , $138-40^\circ$, m. 0° . With Cu at $250-60^\circ$, this gives 5,5'-dichloro-3,3'-ditolyl, m. $101-2^\circ$; no satisfactory results were obtained on attempting to oxidize this. 3-Chloro-5-aminobenzoic acid-HCl, m. $118-21^\circ$; Ac deriv. of the acid, m. $265-7^\circ$. 3-Chloro-5-iodobenzoic acid, reddish yellow, m. $190-1^\circ$; Me ester, orange, m. $43-4^\circ$; with Cu powder at $265-70^\circ$, this gives 25% of the Me ester, m. 156° , of 5,5'-dichlorodiphenyl-3,3'-dicarboxylic acid, m. $358-60^\circ$; the brucine salt, m. $178-9^\circ$, decomps. 193° ; the quinine salt, m. $170-2^\circ$, decomps. 174° , and the acid morphine salt, m. $218-9^\circ$, decomps. $223-5^\circ$, were each uniform and the solns. of NH_4 salt prep'd. from them were in each case optically inactive. The acid does not have the asymmetry of its 2,2',6,6'-structural isomer. C. J. WEST

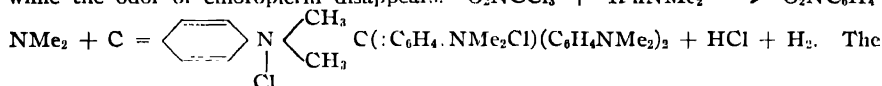

Stereoisomeric bromoimino ketones. HOYLAND E. YOUNG. *Abstracts of Theses, Univ. Chicago, Science Series* 4, 203-7(1925-6) (publ. May, 1928).—Six bromoimino ketones were prep'd. from aromatic imines according to the equation: $\text{RC}(\text{NH})\text{R}' + \text{HOBr} = \text{RC}(\text{NBr})\text{R}' + \text{H}_2\text{O}$. It was attempted to sep. each of the products obtained into 2 stereoisomeric forms; this was accomplished only in the case of bromoimino-*p*-chloro- and *p*-bromobenzophenone. In both cases evidence for the existence of a 3rd isomer was found. The isomer with the higher m. p. was called α -form, the other β -form. Bromoiminobenzophenone, m. 41° . Bromoimino-*p*-methoxybenzophenone (I), m. 95° . I reacts with Br giving 3 substances: red, m. 133° ; yellow, m. 105° ; orange, m. 134° . Bromoimino- β -naphthophenone, m. 102° . Bromoimino-*p*-chloro-*p*-methoxybenzophenone, m. 77.5° . Stereoisomeric bromoimino-*p*-chlorobenzophenones: α -form, pyramids and plates, m. 109° , and β -form, needles and plates, m. 85° (from *p*- $\text{ClC}_6\text{H}_4\text{CPh:NH.HCl}$ and KOBBr). The crude reaction product was sep'd. into the isomers by dissolving it in ligroin out of which at -20° principally the α -form crystd. Evapu. of the filtrate yielded the β -form. Stereoisomeric bromoimino-*p*-bromobenzophenones: α -form, plates, m. 104° , and β -form, prisms, m. $102-3^\circ$, were sep'd. by means of cold CHCl_3 and ligroin. The 3rd isomer, plates, m. $102-3^\circ$, was only obtained occasionally. G. SCHWOCH

***p,p'*-Diiododiphenylmethane.** A. M. NASTUKOV and V. V. SHEL'YAGIN. Univ. Moskau. *J. prakt. Chem.* 119, 303-5(1928).—Condensation of 100 g. formalin and 200 g. PhI with 100 cc. concd. H_2SO_4 by boiling 2 hrs., gives 16 g. *p,p'*-diiododiphenylmethane, m. $92-3^\circ$; its structure was established by oxidation to (*p*- IC_6H_4)₂ CO , m. 234° . C. J. WEST

2,4,7-Trinitrofluorenone. FRANK BELL. Battersea Polytechnic. *J. Chem. Soc.* 1928, 1990.—4-Nitrofluorenone, heated 2 hrs. on the steam bath with HNO_3 (d. 1.5),

gives 2,4,7-trinitrofluorenone, m. 175°. The same product was obtained by the nitration of fluorenone according to Schmidt and Bauer (*Ber.* 38, 3758(1905)), who stated that the product was the 2,3,7-tri-NO₂ deriv. Oxidation gave a very small quantity of an impure acid, m. 165–70°, which, if purified, would obviously m. higher than 3,4-(O₂N)₂-C₆H₃CO₂H (164°). C. J. WEST

New synthesis of methyl violet. G. D. SUTCHEV. Tomsk. Gosud. Univ. J. Chem. Ind. (Moscow) 5, 72–3(1928).—In the Ger. pat. 12,096 it is indicated that by the action of 3 parts chloropicrin on a mixt. of 7 parts PhNMe₂ and 3 parts BzH 2 dyestuffs are formed, which are not named. S. supposes that the 2 dyestuffs in question are Me violet and malachite green. According to S. the addn. of BzH in the reaction of formation of Me violet is not only useless, but even harmful. Ten g. chloropicrin and 30 g. PhNMe₂ are mixed in a hermetically stoppered flask and left standing under the hood at room temp. (16–8°) for 8 days. At first the nitro group of chloropicrin is split off and the nitration of PhNMe₂ takes place, as indicated by the appearance of a cherry-red coloration after 24 hrs. Then Cl is split off and the 1st signs of formation of Me violet appear after 3–4 days. The liquid thickens, darkens and finally crystallizes, while the odor of chloropicrin disappears. O₂NCCl₃ + 4PhNMe₂ → O₂NC₆H₄-

cryst. Me violet is extd. from the product of reaction by soln. in cold water and can be sepd. from this soln. by NaCl. The yield of the dyestuff is 24 g., i. e., 76.7% of the theoretical. The residuc, which is not sol. in cold water but slightly sol. in hot water from which it can be crystd., is *p*-nitrodimethylaniline of which 6 g. is obtained, the yield being 58.7% of the theoretical. Among other products obtained, aside from changed PhNMe₂, was a little *p*-phenylenediamine. S. thinks that his method has the following advantages over the 2 methods at present used for the manuf. of Me violet: (1) the reaction takes place in 1 phase, without heating and in a simple app. (a closed kettle could be used); (2) the methods of sepn. of the reaction products are simple; (3) technical (non-refined) chloropicrin and PhNMe₂ could be used for the manuf.; (4) traces of Cu accelerate the reaction approximately 2–3 times; (*p*-O₂NC₆H₄NMe₂, which is obtained as by-product is a valuable intermediate).

BERNARD NELSON

Theory of the betaines. III. P. PFEIFFER, H. BEHR, BR. BREYER, O. CLARENZ AND H. KUBLER. Univ. Bonn. *Ann.* 465, 20–52(1928); cf. C. A. 17, 62–4.—Since in the earlier work it was not possible to obtain a *cis-trans*-isomeric pair of betaines and since there was the possibility that the *trans*- might rearrange into the *cis*-form during the formation of the betaine, the work has been continued and now definite pairs of isomers have been obtained. *cis-m-Amino-α-phenylcinnamic acid* (I), by the reduction of the NO₂ deriv. (for which an improved method of sepn. is given), pale yellow, m. 189–91°, crystals with 1EtOH; P₂O₅ in CHCl₃ gives a deep orange ppt.; the H₂SO₄ soln., on heating, becomes dark orange to red; *HCl* salt, m. 229–32° (decompn.); *Bz* deriv., m. 184–5°, crystg. with 1H₂O; AcOH gives anhyd. crystals. The *trans-isomer* (II) pale yellow, m. 192°; P₂O₅ causes no change, while H₂SO₄ gives a red color only on long heating. *Bz* deriv., m. 255–6°; *Me* ester, pale yellow, m. 117°; *Et* ester, m. 65°. I, twice methylated with MeI and MeOH-KOH, gives the *dimethylamino methiodide*, m. 158° (decompn.); the aq. soln. with Ag₂O gives the *trimethylbetaine* of I, crystg. with 1H₂O, m. 186–8° (decompn.), the aq. soln. reacts neutral to litmus; heating a short time with concd. H₂SO₄ gives a blood-red soln. The *HCl* salt, m. 178° (decompn.); *HBr* salt, m. 170° (decompn.); the *nitrate*, m. 144–6° (decompn.); the *perchlorate*, m. 170° (decompn.); the *chloroplatinate* crystals with 1H₂O and m. 168° (decompn.). The *methiodide* of the *dimethylamino* deriv. of II, m. 163–7°, the *trimethylbetaine*, crystg. with 1H₂O, m. 112–4°; the warm concd. H₂SO₄ soln. is a pale greenish yellow; *HCl* salt, m. 163° (decompn.); *HBr* salt, crystg. with 1H₂O, m. 148–52° (decompn.); the *nitrate*, m. 166–9° (decompn.); the *perchlorate*, m. 173° (decompn.); the *chloroplatinate*, orange, m. 196°. *p*-Me₂NC₆H₄CHO and *p*-O₂NC₆H₄CH₂CN in 20% EtOH-NaOH give *p*-dimethylamino-*p*-nitro-*μ*-cyanostilbene, from C₆H₆ reddish brown, from AcOH violet-red, m. 240–1°; *methiodide*, needles, crystg. with 2H₂O. The sapon. with concd. H₂SO₄ gives 2 *amides* (III), m. 221–2°, cinnabar-red, sepd. by its soly. in C₆H₆ and (IV), reddish orange, m. 256°; with P₂O₅, both amides give the same nitrile. With MeOH-HCl, III gives a *Me* ester, orange, m. 169–70°; *Et* ester (V), light red, m. 134–5°. IV gives a mixt. of the *Et* ester, m. 134–5°, and a violet-red ester, m. 138–9°. The *free acid* forms red-orange needles, m. 249°. V and MeI give a *methiodide*, orange, m. 160–1° (decompn.); with

Ag_2O this yields the *betaine*, $^+\text{Me}_2\text{NC}_6\text{H}_4\text{CH}$, m. 210–1°; *perchlorate*, decomps.

explosively. *m*-Dimethylaminocinnamic acid-*MeI*, m. 202–3°; Ag_2O gives the *trimethylbetaine*, crystg. with $2\text{H}_2\text{O}$, m. 128° or anhyd., m. 206–7°; *HBr salt*, m. 196°; *perchlorate*, m. 230–1°. *p*-Dimethylamino-*o*'-amino-*p*'-cyanostilbene, brownish to greenish yellow, m. 226°; *HI* salt; *methiodide*, light yellow, m. 203°. *Me p*-dimethylamino-*o*'-nitrostilbene-*p*'-carboxylate-*MeI*, greenish yellow, m. 192°; the *Et ester-MeI*, yellow, m. 147°; *nitrate*, greenish yellow. The *betaine*, $\text{C}_{15}\text{H}_{18}\text{O}_4\text{N}_2$, results from the *Me ester-MeI* with Ag_2O , grayish, m. 210–20°, contg. $3\text{H}_2\text{O}$, the anhyd. *betaine*, m. 220–2°; it is also obtained from the nitrile-*MeI* deriv.; *Cl salt*, canary-yellow; the *dihydrate* is yellow. *p*-Dimethylamino- μ' , μ' -*dicyanostilbene*, yellow-orange, m. 205°. Sapon. with MeOH-HCl gives *Me p*-dimethylamino- μ' -cyanostilbene-*p*'-carboxylate, yellowish orange, m. 178°; *Et ester*, golden yellow, m. 145°, the *methiodide* of the latter, ocher-yellow, Ag_2O gives the *betaine*, m. 250°; it crysts. with $1.5\text{H}_2\text{O}$, *HCl salt*, crystg. with $2\text{H}_2\text{O}$. C. J. WEST

Relative reactivity of methylene groups in 1,3-diketones. ARTHUR BERTRAM, E. LOVETT AND ELWYN ROBERTS. Univ. of London. *J. Chem. Soc.* 1928, 1975–9.—This study was designed to discover which CH_2 group, in a diketone of the general formula $\text{CH}_2\text{RCOCH}_2\text{COR}'$, would be the more reactive as regards the condensation with aldehydes; in $\text{PhCH}_2\text{COCH}_2\text{Bz}$ (I), the more reactive CH_2 group is that adjacent to the Ph group, since the product from $\text{HOC}_6\text{H}_4\text{CHO}$ ($\text{HOC}_6\text{H}_4\text{CH CPhCOCH}_2\text{Bz}$) gives PhAc and 3-phenylcoumarin (II) on hydrolysis. The formation of II cannot be attributed to an initial hydrolysis, giving rise to $\text{PhCH}_2\text{CO}_2\text{H}$ and PhAc, since $\text{PhCH}_2\text{CO}_2\text{H}$ does not condense with $\text{HOC}_6\text{H}_4\text{CHO}$ to give II. Propionylacetophenone, b_p 149°, b_d 151°, gives a green salt, m. 151–2°; the *p*-nitrophenylhydrazone, yellow, m. 67–8°; with PhNH_2 there results propionylacetophenonanal, m. 48–9°. I and *o*- $\text{HOC}_6\text{H}_4\text{CHO}$ give *o*-hydroxybenzylidene phenylacetylacetophenone, m. 171–4°; the yield depends upon the quantity of piperidine used; BzII and $\text{PhCH}_2\text{CHCHO}$ gave resins. The use of substituted *o*- $\text{HOC}_6\text{H}_4\text{CHO}$ gave derivs. of II directly, the intermediate product not being isolable. The following derivs. of II were thus prepd.: 6-*Cl*, pale yellow, m. 199° (25% yield; 40% obtained by Perkin's reaction; these 2 values will be given for the following derivs.); 6-*Br*, pale yellow, m. 189–91° (25, 62); 6-*NO}_2* deriv., yellow, m. 146–7.5° (4, 60); 6-*Me*, pale yellow, m. 146–7.5° (42, 40); 8-*NO}_2*, pale yellow, m. 236–9° (4, 65); 6,8-*di-Cl*, m. 193 4.5° (16, 17), 6,8-*di-Br*, m. 186–7.5° (trace, 30); 6,8-*di-NO}_2*, pale yellow, m. 244–6° (0, 60); 6-*Cl*-8(*p*)-*NO}_2*, m. 212–4° (0, 70); 6-*Br*-8-*NO}_2*, m. 228–30° (trace, 74); 6-*Me*-8-*NO}_2*, yellow, m. 180 2° (12.5, 44). 3,5-Dinitrosalicylaldehyde, lemon-yellow, m. 58–60°. 5-Chloro-3(?)-nitrosalicylaldehyde, yellow, m. 105–7°. I and 2,1- $\text{HOC}_{10}\text{H}_8\text{CHO}$ give the compd. $\text{C}_{27}\text{H}_{18}\text{O}_4$, deep blood-red, m. 155–6°. C. J. WEST

The relative stabilities of isomers (according to their absorption spectra). Transpositions in the series of glycols and of aldehydes. MME. RAMART-LUCAS AND F. SALMON-LEGAGNEUR. *Compt. rend.* 186, 1848–50 (1928); cf. *C. A.* 22, 2717, 3154.—The dehydration of glycols by heat takes the course: glycol \rightarrow aldehyde \rightarrow ketone. $\text{Ph}_2\text{C}(\text{OH})\text{CH}_2\text{OH}$ and $\text{PhEtC}(\text{OH})\text{CH}_2\text{OH}$ when heated at 250–300° yield exclusively the corresponding aldehydes; at 400–450° these glycols yield only ketones. $\text{PhCH}(\text{OH})\text{CH}(\text{OH})\text{Ph}$ (I) heated at 250–300° gives Ph_2CHCHO (II) and a little unchanged I; at 400–450° PhCH_2COPh (III) is the chief product. (A little BzH is formed by the dissocn. of I.) II when heated at 400–450° is entirely transformed into III. A mechanism is given for these changes. REYNOLD C FUSON

Action of phthalyl chloride on *m*-methoxybenzoic acid and *m*-cresyl methyl ether. RICHARD WEISS AND WALTER KNAPP. Univ. Wien. *Monatsh.* 50, 10–15 (1928).—*m*- $\text{MeOC}_6\text{H}_4\text{CO}_2\text{H}$ (22 g.) and 30 g. *o*- $\text{C}_6\text{H}_4(\text{COCl})_2$ in 80 cc. CS_2 , treated with 35 g. AlCl_3 , give 40% of 4'-methoxybenzophenone-2,2'-dicarboxylic acid diacetone, m. 183°. *m*- $\text{MeOC}_6\text{H}_4\text{Me}$, *o*- $\text{C}_6\text{H}_4(\text{COCl})_2$, AlCl_3 and CS_2 give 80% of *m*-cresolphthalein di-*Me ether*, yellow, amorphous product; reduction with Na-Hg in MeOH gives 75% of *m*-cresolphthalein di-*Me ether*, crystg. from MeOH with 0.75 mol. MeOH; with KMnO_4 in dil. NaOH, this is oxidized to dimethoxytriphenylmethanetricarboxylic acid, amorphous; the *Me ester* is also amorphous. Heating with ZnCl_2 at 200° for 15 min. splits off H_2O , giving 1,2'-dimethoxy-9-phenylanthrone-3,4'-dicarboxylic acid, amorphous, dark red flakes, which decomps. 250° in a vacuum. C. J. WEST

New *o*-azo compounds. JAKOB POLLAK AND ERICH GEBAUER-FÜLNEGG. Wien Univ. *Ans. Akad. Wiss. Wien* 63, 145 (1927).—A comment on the work by ROWE (*C. A.* 20, 1802). In analogy with the formation of an *o*-azo compd. (diazo ether) (Bucherer,

C. A. 3, 902) in the reaction between diazotized *p*-nitroaniline and 2,1- $C_{10}H_6(OH)SO_3H$, and in contradistinction with Hewitt and Mitchell (*J. Chem. Soc.* 89, 1169(1906)) and Wahl and Lantz (*C. A.* 17, 2577), an intermediary *o*-azo deriv. was detected during the coupling of 2,1- $C_{10}H_6(OH)Br$, or similar compds. with diazotized *p*-nitraniline. The diazo ether isomerizes by crystn. into the normal azo deriv. of β -naphthol. This weak stability explains the results of the previous authors. A. L. HENNE

The action of some sulfur compounds on 1-chloro-2,4-dinitronaphthalene, 1-chloro-2,4,5-trinitronaphthalene and 1-chloro-2,4-dinitrobenzene. H. W. TALEN. Univ. Leiden. *Rec. trav. chim.* 47, 782-95(1928); cf. *Rec. trav. chim.* 20, 115, 121(1901); *C. A.* 21, 404; 22, 1350-1.—(In the following $R = 2,4,1-C_{10}H_5(NO_2)_2$ —.) An alc. soln. of 0.4 g. crystd. Na_2S was added 1 g. RCI in 100 cc. $EtOH$; after boiling for a few min. and cooling a ppt. of 2,4,2',4'-tetranitrodinaphthyl-1-sulfide, m. 283° from Ac_2O , is obtained. The same compd. is obtained when the reaction is carried out with an equimol. quantity of Na_2S_2 , 2,4,2',4'-tetranitrodinaphthyl disulfide not being formed in this way. This compd. could be prepd. in the following way: A warm alc. soln. of 0.95 g. crystd. Na_2S is added rapidly to 1 g. RCI in 100 cc. warm alc.; after standing for 5 min. the soln. of the Na salt of RSH thus obtained, is dild. with 5 times its vol. of water and concd. aq. $I-KI$, contg. 0.5 g. I , is added. An orange-yellow ppt. of 2,4,2',4'-tetranitrodinaphthyl-1-disulfide, decomp. explosively at 230° (from $AcOH$) is formed at once. On acidification of the above aq. alc. soln. of the Na salt of 2,4-dinitro-1-thionaphthol, the latter ppts., m. $117-8^\circ$; on exposure to air, it is oxidized to the disulfide. In the same way in which R_2S is formed from RCI , 2,4,5,2',4',5'-hexanitrodinaphthyl-1-sulfide, m. 323° from Ac_2O , is formed from 2,4,5,1- $C_{10}H_4(NO_2)_4Cl$ and Na_2S , the same product being obtained also by means of Na_2S_2 . The product formed by the interaction of $EtOCS_2Na$ and 2,4-(O_2N) $_2C_6H_3Cl$ (I) is dependent on the relative quantities of the reacting components, with 1 mol. of each 2,4,2',4'-tetranitrodiphenyl disulfide, exploding 280° (from $PhNO_2$), being the chief product and with 1 mol. $EtOCS_2Na$ and 2 mols. I 2,4,2',4'-tetranitrodiphenyl monosulfide, m. 196° from alc.-acetone, being the chief product of the reaction. The monosulfide is formed by the interaction of I and 2,4-(O_2N) $_2C_6H_3SH$, produced intermediately, while the disulfide is formed by atm. oxidation of the 2,4-(O_2N) $_2C_6H_3SH$. $C_6H_5(NO_2)_2SH + Cl(NO_2)_2C_6H_3 \rightarrow [C_6H_5(NO_2)_2]_2S + HCl$. Both these reactions were carried out in the way described above for the $C_{10}H_8$ derivs. About equal quantities of 2,4,2',4'-tetranitrodiphenyl mono- and disulfide are formed on boiling 1 mol. $CS(NH_2)_2$ and 1 mol. I in alc. during an hr., but the disulfide is the principal product of the reaction of 2 mols. of $CS(NH_2)_2$ and 1 mol. I in alc. On boiling 1 mol. $CS(NHPh)_2$ and 2 mols. I in alc., 1-anilino-2,4-dinitrobenzene, m. 157° , and [2,4-(O_2N) $_2C_6H_3]_2S$, are formed, the same products being obtained with 2 mols. $CS(NHPh)_2$ and 1 mol. I. In these reactions with $CS(NH_2)_2$ and $CS(NHPh)_2$ it is essential for the formation of the mono- and disulfide, that the HCl , set free during the reaction, should be neutralized. The interaction of 1 mol. $EtOCS_2Na$ and 1 mol. RCI gives rise to the formation of R_2S , ROH and 2,4-dinitronaphthyl 1-Et disulfide, m. 85° , from alc. The occurrence of this compd. is best explained by the assumption, put forward and made highly probable by Weeldenburg (*Diss. Delft* 1927, p. 86) that in a xanthogenate soln. an equil. exists between 2 isomeric forms, the *O*- and the *S*-ester, $CS(SNa)OEt$ and $CO(SNa)SEt$. The reaction between 1 mol. $CS(NH_2)_2$ and 1 mol. RCI yields R_2S , the formation of which also predominates in the interaction of 2 mols. $CS(NH_2)_2$ and 1 mol. RCI . Attempts have been made to prep. $RCNS$ (a) by the interaction of $KSCN$ and RCI in alc., R_2S , however, being formed, apparently the thiocyanate being hydrolyzed in the alk. medium; (b) by the same reaction with NH_4CNS , thus avoiding a strong alk. reaction of the medium. In this way a mixt. of 2,4,1- $C_{10}H_6(NO_2)_2CNO-RCNO$ and unchanged RCI was obtained, which could not be sepd., since decompn. readily occurred on warming. C. F. VAN DUIN

Action of chlorosulfonic acid on phenols. IV. JAKOB POLLAK, ERICH GEBAUER-FULNEGG and EUGEN BLUMENSTOCK-HALWARD. Univ. Wien. *Monatsh.* 49, 187-202 (1928); cf. *C. A.* 21, 2676.—(WITH EDUARD PETERTIL.) $ClSO_3H$ (I) acts on α - $C_{10}H_7OH$ (II) at the ordinary temp., the 2- SO_3H deriv. crystg. out. With an excess of I (5 times the wt. of II for 2.5 hrs., or 10 times, for 1.5 hrs.), there results 1-naphthol-2,4-disulfonyl chloride, m. 149° (anilide, m. 228°). Prolonged action (4-5 days) gives 1-naphthol-2,4,7(?)-trisulfonyl chloride, m. 172° (with 0.5 C_6H_6 , 160°); anilide, m. 240° (decompn.). Alk. hydrolysis splits off 2 SO_3H groups, giving probably the 7- SO_3H deriv. At 100° , I and II give the 4- SO_3H deriv.; at 160° , a black product, or with an excess of I, a resinous product, is obtained, from which a trichloronaphthalenesulfonyl chloride, m. 214° , is isolated. (WITH KURT WINTER.) The action of I upon β - $C_{10}H_7OH$ (III) at the ordinary temp. gives only the 1- SO_3H deriv.; on standing, a mixt. of disulfonyl chlorides

is obtained. In $C_2H_2Cl_4$ at 130° , there results the β - SO_3H deriv. Excess of I yields a mixt. of 2 *disulfonyl chlorides*, m. 111° (IV) and 177° (V), whose constitution is studied in the following abstr. The anilide from IV m. 191° , from V, 231° . Heating I and III at $130-40^\circ$ gives 2-naphthol-3,6,8-trisulfonyl chloride, m. 196° (anilide, m. $152-5^\circ$), also obtained from *O*-carbethoxy-2-naphthol-3,6,8-trisulfonyl chloride). Heating III with 50 parts I 80 hrs at $150-60^\circ$ gives a compd. contg. Cl but not S, m. $120-2^\circ$ (a dichloronaphthalene?) and a S-contg. compd., m. $135-40^\circ$, probably a naphthoquinone deriv.

C. J. WEST

Constitution of the β -naphtholdisulfonyl chlorides. J. POLLAK and EUGEN BLUMENSTOCK-HALWARD (WITH ALEXANDER SCHLESINGER, VIKTOR WEINMAYR and KURT WINTER). Univ. Wien. *Monatsh.* **49**, 203-12(1928); cf. preceding abstr.— $ClSO_3H$ and 2,6(or 1)- $C_{10}H_6(OH)SO_3H$ give β -naphthal-1,6-disulfonyl chloride, m. 111° , which establishes the structure of IV in the preceding abstr. 2,8- $C_{10}H_6(OH)SO_3H$, which might give the chloride, m. 177° , gave instead the 6,8-disulfonyl chloride (I), m. $161-2^\circ$ (anilide, m. 195°). The constitution of I is established by reacting 2,6,8- $C_{10}H_6(OH)(SO_3H)_2$ with $ClCO_2Et$ and then with $ClSO_3H$, giving *O*-carbethoxy- β -naphthal-6,8-disulfonyl chloride, m. 131° , whose anilide, m. 178° , on hydrolysis, gives the anilide of I. Similarly 2,3,6- $C_{10}H_6(OH)(SO_3H)_2$ gives *O*-carbethoxy- β -naphthal-3,6-disulfonyl chloride, m. 125° (anilide, m. $153-63^\circ$, which was not purified but hydrolyzed to 2-naphthol-3,6-disulfonanilide, m. 202°), this was not identical with the anilide from the chloride, m. 177° , as might be expected from the conversion of the latter into 2,3,6,8- $C_{10}H_4(OH)(SO_2Cl)_3$; this acid deriv., however, is also obtained from the chloride, m. 111° , which involves the migration of the SO_2Cl group from the 1-position. It is, therefore, suggested that the chloride, m. 177° may be the 1,8 deriv. Since 2,1- $C_{10}H_6(OH)SO_2Cl$ (Anschutz and Maxim, *C. A.* **13**, 431) does not form a sulfonyl chloride, it was thought that the SO_2Cl group might be in some other position, *O*-acetyl-2-naphthol-6- and 8-sulfonyl chlorides, m. 103° and 129° , resp., were therefore prepd. Since these are different from the compd. of A and M., there is no reason to question their structure. The 6-sulfonanilide, m. 95° , on hydrolysis gives 2,6- $C_{10}H_6(OH)SO_2NIPh$, m. 161° ; this m. p. does not agree with that of Zincke and Dercser (*C. A.* **12**, 2559), viz. $100-5^\circ$, the anilide was prepd. by their method and found to contain 2 mols. H_2O , m. $100-5^\circ$, but on crystn. from C_6H_6 , it m. $160-1^\circ$; recrystn. from H_2O did not again give the low-melting form, which must be regarded as a labile form *O*-Carbethoxy-2-naphthol-8-sulfonyl chloride, m. 118° ; anilide, m. 195° ; hydrolysis gives 2-naphthol-8-sulfonanilide, m. 195° , also obtained from the *O*-Ac deriv.

C. J. WEST

Action of bromine on naphthosulfonic acids. A remarkable color reaction in solution. G. HELLER, W. EISENSCHMIDT, G. REICHARDT and H. WILD. *Z. angew. Chem.* **41**, 171-7(1928).—On treatment with 2 mols. of Br in cold AcOH naphthosulfonate gives 4-bromonaphthosulfonate, m. 199° . Na naphthosulfonate-4-sulfonate and Na 1,4,8- $C_{10}H_6(OH)(SO_3Na)_2$ afford the same product when Br in AcOH is added to their aq. soln. acidified with H_2SO_4 . When treated with alkali in satd. soln. in presence of excess of solid, undissolved crystals of Na 2,4-dibromo-1-naphthol-8-sulfonate (obtained by brominating 1,8- $C_{10}H_6(OH)SO_3Na$ in a freezing mixt.) developed a reddish blue color which diffuses through the soln. and after some min. fades to olive-brown. The coloration is due to the formation of the quinhydrone of 2-bromo-1,4-naphthoquinone-8-sulfonic acid (Na salt, reddish brown crystals with green reflex), the latter being also produced by the addn. of $K_3Fe(CN)_6$ to the filtered soln. of the dibromonaphthosulfonate, and when the soln. of 1,8- $C_{10}H_6(OH)SO_3Na$ is only cooled with ice for bromination. 1,2,4,8- $C_{10}H_4(OH)(SO_3Na)_3$ affords the same quinhydrone. With excess of Br (4 mols.) Na 1-naphthol-8-sulfonate, 2,4,8-trisulfonate and 3,8-disulfonate all afford Na 2,3-dibromo- α -naphthoquinone-8-sulfonate, yellow, which is readily reduced to a colorless quinol, and with *p*-toluidine in alc. yields 3-bromo-2-*p*-toluidino- α -naphthoquinone-4-*p*-methylamyl-8-sulfonic acid, carmine-red, anthranilic acid giving an analogous deriv. With 1 mol of Br, 1,3,8- $C_{10}H_6(OH)(SO_3Na)_2$ gives Na 4-bromo-1-naphthol-3,8-disulfonate, which couples with diazotized *p*-toluidine to give 4-bromo-2-*p*-toluenazo-1-naphthol-3,8-disulfonate, and on treatment with a further mol. of Br affords Na 2-bromo- α -naphthoquinone-3,8-disulfonate, red needles, and traces of Na 3,4-dibromo-1-naphthol-8-sulfonate, which forms no quinone. Bromination of 1,3,6- $C_{10}H_6(OH)(SO_3Na)_2$ gives the readily sol. Na 2-bromo- α -naphthoquinone-3,6-disulfonate, yellow, which could not be obtained pure. Treatment of Zn 1-naphthol-4-sulfonate with 1 mol. of Br affords 2,1,4- $C_{10}H_6Br(OH)SO_3H$ (*K* salt), the constitution of which follows from its inactivity towards alc. *p*-toluidine and diazonium salts. With a further mol. of Br this *K* salt gives *K* 2,3-dibromo-1-naphthol-4-sulfonate. With 4 mols. of Br Zn 1-naphthol-4-sulfonate gives 2-bromo-1,4-naphthoquinone, m. $127.5-28^\circ$ (Zincke and Schmidt,

Ber. 27, 2753-62(1894)), together with a little 2,3-dibromonaphthoquinone, m. 216-7°. 4-Bromonaphthosulfone is converted by 10% NaOH into *Na 4-bromo-1-naphthol-8-sulfonate*, which with 3 mols. of Br gives *Na 2,3-dibromo- α -naphthoquinone-8-sulfonate*, and with diazotized *p*-toluidine, *Na 4-bromo-2-p-tolueneazo-1-naphthol-8-sulfonate*, analysis indicating displacement of Br and coupling in the 4-position to a slight extent. *Na 1-naphthol-2-p-tolueneazo-8-sulfonate* is described. 2,6-C₁₀H₆(OH)(SO₃)Na yields *Na 1-bromo-2-naphthol-6-sulfonate* and a *dibromo-2-naphthol-6-sulfonate*. 2,3,6-C₁₀H₅(OH)(SO₃H)₂ similarly affords mono- and di-Br-derivs., and 2,6,8-C₁₀H₅(OH)(SO₃H)₂ an easily sol. *Na tribromo-2-naphtholsulfonate*. 2,3,6,7-C₁₀H₄(OH)(SO₃H)₃ with 1 mol. of Br gives *Na 1-bromo-2-naphthol-3,6,7-trisulfonate* (sparingly sol. *p*-toluidine salt; does not couple with diazonium salts). In no case was quinone formation observed in the bromination of β -naphtholsulfonic acids. The quinone formation observed by Armstrong and Graham (*J. Chem. Soc.* 39, 137 (1881)) was probably due to the presence of α -naphthol in their β -naphthol.

Dinitrobindone and its scisson products. W. WISLICENUS AND H. SCHLICHENMAIER. *Ann.* 460, 278 88(1928).—Bindone in AcOH and concd. HNO₃ gives 40-5% of the *di-NO₂ deriv.* (I), m. 183°. With EtOH-KOH, I gives a red K salt of the unstable acid C₆H₄(CO)₂C·C(C₆H₄CO₂H)C(NO₂)₂·NO₂H (II), m. 94°, while Br and aq. KOH give the pale yellow *compd.* C₆H₄(CO)₂C·C(C₆H₄CO₂H)C(NO₂)₂·Br (III), exploding at 117°. When I is treated with ice-cold KOH and the red soln. is at once acidified, *phthalideneindandione* (IV), m. 253°, results, CH₂(NO₂)₂ being split off at the acidification stage. By prolonged heating of I with aq. KOH at 100°, CH(NO₂)₂K is formed, exploding at 204°. EtOK and I give the deep red K salt of the *Et ester* of II, m. first at 132° but changes rapidly to 124°; similarly, MeOK gives the K salt of the *Me ester*; the latter salt with Br gives a *tri-Br deriv.*, pale yellow, m. 139°. NH₄OH converts I into the *lactam* (V), C₁₇H₇NO₄, pale yellow, m. 265°, and CH₂(NO₂)₂, while if NH₃ is passed into I in C₆H₆ there results the *NH₃ salt of the amide* of II, red, decomp. 183°; the free amide is very unstable. I and PhNH₂, allowed to stand 48 hrs., give the *phenylammonium salt*, easily decompd., of the *anilide* of II, decomp. 125-8°; the salt, treated with warm MeOH-HCl, yields the *phenylimide*, orange-yellow, m. 234°, stable to acids and only slowly hydrolyzed by alkali. V, warmed with aq. NaOH, gives *2-o-carboxybenzoylindandione*, *crystg.* with 1MeOH, m. 155-60° (*cu salt*, green; *Me ester*, m. 123°). Bromination of II in CHCl₃ gives the *2-Br deriv.*, which rapidly passes into *dibromodiketohydrundene*, m. 175°, which is also formed by treating the acid in NaHCO₃ soln. with Br-H₂O.

Synthesis of meso-alkyl- and meso-arylanthracene derivatives. IV. EDWARD DE B. BARNETT AND JOHN L. WILTSHIRE. Sir John Cass Tech. Inst. *J. Chem. Soc.* 1928, 1822-5; cf. C. A. 22, 1972.—In the reaction of 2-chloro-9-anthrone (I) with Grignard reagents, only good yields are obtained with the Et and PhCH₂ derivs. Reduction of *o*-(4-ClC₆H₄CO)C₆H₄CO₂H by Zn in NH₄OH by heating on the H₂O bath for 20 hrs. gives *4-chlorodiphenylmethane-2'-carboxylic acid*, m. 132°; with concd. H₂SO₄ this gives I, m. 155° (cf. Mayer and Fischbach, C. A. 19, 2950); since this differs from the β -chloroanthrone of Barnett and Matthews (C. A. 18, 256) the latter must be the *3-Cl deriv.* (II); the *acetate* of I, m. 143°; of II, m. 146°. With I and the Grignard reagent, the following *comps.* were prepd.: *2-Chloro-9-methylantracene*, m. 84°; *9-Et deriv.*, m. 79° (*10-Br deriv.*, yellow, m. 128°); *9-Pr deriv.*, m. 82°; *9-benzyl deriv.*, m. 132° (*10-Br deriv.*, yellow, m. 167°; with an excess Br, a *bromo dibromide*, cream-colored, m. 150° (decompn.) results).

Stereochemistry of aromatic compounds. VI. An optically active vat dye without asymmetric carbon atom; *d*- and *l*-1,1'-dianthraquinonyl-2,2'-dicarboxylic acid. RICHARD KUHN AND OTTO ALBRECHT. Techn. Hochschule, Zürich. *Ann.* 464, 91-100 (1928); cf. C. A. 22, 413.—1,1'-Dianthraquinonyl-2,2'-dicarboxylic acid (I) and quinine give a ppt., purified by extg. with EtOH, of *quinine d-I*, m. 249-50°, [α]_D¹⁸ 369° (C₆H₅N); from the EtOH mother liquors a *quinine l-I*, decomp. 193°, [α]_D¹⁸ -110.7° (C₆H₅N). The *l-I*, m. 273°, [α]_D¹⁸ -237° (0.1 N NaOH); the *d-I*, m. 260°, [α]_D¹⁸ 346° (0.1 N NaOH); a mixt. of the 2 acids gives the *dl-acid*, m. 351-3°. The *d-I* is stable in 0.1 N NaOH at 140-60°, in Ac₂O at 99° and at the b. p. of Ac₂O showed a drop from 100.3° to 78.3° in 3.5 hrs. The optically active acid also shows no change when treated with NaHSO₄, and regenerating the acid from the red vat with O. Attempts at asym. dyeing failed.

C. J. WEST

Course of the Friedel-Craft reaction with anthraquinone-1,2-dicarboxylic anhydride. GUIDO MACHEK AND ANTON GRAF. Univ. Innsbruck. *Monatsh.* 50, 6-9(1928).—C₆H₄(CO)₂C₆H₃(CO)₂O (2 g.), 60 g. C₆H₆ and 6 g. AlCl₃, heated to boiling 2 hrs., give

3.3 g. of *anthraquinone-1,2-dicarboxylic diphenylphthalide*, m. 180–2°; the corresponding *HO acid*, m. 143–6°.

C. J. WEST

Constitution and mode of reaction of polynuclear polyhydroxyquinones. Naphthazarin and quinizarin. KARL ZAHN AND PAUL OCHWAT. I. G. Farbenindustrie Aktiengesellschaft Höchst a. M. *Ann.* **462**, 72–97(1928).—Heating a mixt. of 100 g. AlCl_3 and 20 g. NaCl with 10 g. maleic anhydride and 11 g. $p\text{-C}_6\text{H}_4(\text{OH})_2$ at 200–20° gives 4 g. naphthazarin (I), whose di-Ac deriv. m. 192–3°. Reduction of 5 g. I suspended in 60 cc. Et_2O with Zn and dil H_2SO_4 gives 1,4,5,8-tetrahydroxynaphthalene (II), m. 190°; the EtOH soln. shows a violet fluorescence; in the enolic form it is unstable and the solid form or solns. rapidly turn red in the air; $\text{Br-H}_2\text{O}$ and FeCl_3 instantly give I; the brown-red NaOH soln. turns blue very quickly with the sepn. of the Na salt of I. Heating a concd. EtOH soln. of II contg. some HCl to boiling in the absence of air gives 1,4-diketo-1,8-dihydroxy-1,2,3,4-tetrahydronaphthalene (III), m. 153–4°, identical with the compd. obtained from I and SnCl_2 and with that from heating succinic anhydride and $p\text{-C}_6\text{H}_4(\text{OH})_2$ with AlCl_3 and NaCl at 220°; this is stable in the air, the solns. show a fluorescence; $\text{Br-H}_2\text{O}$ and FeCl_3 have no action. EtOH-NaOH solns. with Me_2SO_4 give 1,4,5,8-tetramethoxynaphthalene, m. 170°. III (3 g.) in 50 cc. Ac_2O and 5 drops concd. H_2SO_4 gives 3.6 g. of the 5,8-di-Ac deriv., decomps. about 220°; the isomeric 1,4,5,8- $\text{C}_{10}\text{H}_4(\text{OH})_2(\text{OAc})_2$ results by the reduction of the di-Ac deriv. of I. $\text{C}_{10}\text{H}_4(\text{OAc})_4$, m. 277–9°, results from either di-Ac deriv. of III by heating with Ac_2O and AcONa . III, heated with $\text{C}_6\text{H}_5(\text{CO})_2\text{O}$, AlCl_3 and NaCl at 220° gives tetrahydroxynaphthacenequinone, reddish brown, m. above 300°; NaOH gives a bluish violet soln.; concd. H_2SO_4 gives a reddish blue soln., changed to greenish blue by H_3BO_3 and showing a characteristic spectrum. The *tetra-Ac deriv.*, yellow, gradually turns red and decomps. on heating. Oxidizing I in AcOH with $\text{Pb}(\text{OAc})_4$ gives 1,4,5,8-naphthodiquinone (IV), pale yellow, decomps. about 220°; heating in EtOH , AcOH or NaOH gives I; it is also reduced in the cold by H_2SO_4 , SnCl_2 and $p\text{-C}_6\text{H}_4\text{O}_2$. Soln. in concd. H_2SO_4 gives naphthopurpurin at once; *tri-Ac deriv.*, light yellow, m. 160–2°. HCl in AcOH gives chloronaphthazarin, dark red, m. 178–9°, identical with the product obtained from I dichloride with AcOH and AcONa ; the *di-Ac deriv.*, m. 193–4°. Satg. I diacetate in AcOH in the cold gives the compd. $\text{C}_{14}\text{H}_{10}\text{O}_6\text{Cl}_2$, m. 136–7°, which, heated in boiling EtOH , gives the above di-Ac deriv., m. 193°. Satg. a suspension of IV in CHCl_3 at 0° with Cl gives naphthodiquinone dichloride, light yellow, decomp. 252–4°; KI at 0° or H_2SO_4 at room temp. gives I. Hydroquinizarin and AcCl in $\text{C}_6\text{H}_5\text{N}$ give 1,4-diactoxy-2,3-dihydroanthraquinone, decomp. 215°; excess AcCl gives 1,4,9,10-tetraactoxyanthracene, pale yellow, m. 240–2°; acetylating with boiling Ac_2O and AcONa gives quinizarin diacetate and also 1,4,9-triactoxyanthracene, pale yellow, m. 210–1°. 5,8-Dichloroquinizarin (V) and PhNH_2 with AcONa , heated at 170°, give 80% of 1,4-dihydroxy-5,8-diaminoanthraquinone, dark blue, m. 258–60°; concd. H_2SO_4 gives a pure green soln., changed by H_3BO_3 to an olive. Reduction of V with Sn and HCl gives the *hydro deriv.*, orange-yellow, which reacts with PhNH_2 and H_3BO_3 to give 1,4-diamino-5,8-dichloroanthraquinone, dark blue, m. 234–5°; concd. H_2SO_4 gives a bluish green color not changed by H_3BO_3 . 2-Methylquinizarin (VI) gives a brownish yellow, *hydro deriv.*, m. 114–5°, which gives with $p\text{-MeC}_6\text{H}_4\text{NH}_2$ at 125° 1-hydroxy-2-methyl-4-*p*-toluidinoanthraquinone, violet-blue, m. 178°; concd. H_2SO_4 gives a greenish blue color, changed by H_3BO_3 to a reddish blue. Oxidation of VI with $\text{Pb}(\text{OAc})_4$ gives 1,3,4-trihydroxy-2-methylanthraquinone (2-methylpurpurin), dark red, m. 265–7° (*Ac deriv.*, red, m. 204–6°; *tri-Ac deriv.*, light yellow, m. 207–8°). Heating a mixt. of 50 g. $o\text{-C}_6\text{H}_4(\text{CO})_2\text{O}$ and 50 g. $p\text{-C}_6\text{H}_4(\text{OH})_2$ with 400 g. AlCl_3 and 80 g. NaCl at 120–5° for 1 hr. gives 48 g. 2,5-dihydroxybenzophenone-2'-carboxylic acid, brownish yellow, m. 189–90°; Me_2SO_4 gives the 2,5-di-MeO deriv., m. 161–2°, which, dissolved in concd. H_2SO_4 and allowed to stand several days at room temp., gives 1,4-dimethoxyanthraquinone (VII), m. 170–1°, identical with the product from quinizarin. Reduction of VII with NaHSO_4 gives 1,4-dimethoxy-2,3-dihydroanthraquinone, yellow, m. 186°, which is stable in the air; concd. H_2SO_4 gives a dark green color, quickly changing to brownish red. The 1,4-di-EtO deriv., olive-brown, m. 174–6°. 1,4-Dimethoxy-9,10-diactoxyanthracene, bright yellow, m. 225°; solns. show a strong green fluorescence; di-EtO deriv., light yellow, m. 203–5°.

C. J. WEST

The mercuration of neutral red and its sulfonic acid. ISRAEL M. LEVINE. *Abstracts of Theses, Univ. Chicago, Science Series* **4**, 105–10(1925–6) (publ. May, 1928).—Mercured neutral red was prepd. on account of its possible therapeutic use. Since this substance proved to be too little sol., sulfonated-mercured neutral red was prepd., the Na salt of which had the desired soly. The formulas given below for the new compds. are the probable ones only, since the positions occupied by the introduced groups

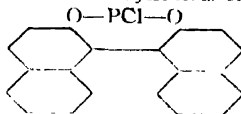

were not detd. exptly. *Acetate of 2,5-diacetoxymercureneutral red* (from neutral red, HgOAc , and $\text{Hg}(\text{OAc})_2$), green, insol. in H_2O . *Chloride of 2,5-dichloromercureneutral red* (from neutral red, HgOAc , $\text{Hg}(\text{OAc})_2$ and NaCl), insol. in H_2O . *Neutral red-2-sulfonic acid* (I) (45% from 5 g. neutral red and 15-cc. fuming H_2SO_4), brown, amorphous, sol. in NaOH and Na_2CO_3 , insol. in H_2O and NaHCO_3 . *Hg salt* of I, insol. in H_2O and alkali. *Na 5-hydroxymercureneutral red-2-sulfonate* (5 g. from 8 g. of I, 4 g. Na_2CO_3 and 7.5 $\text{Hg}(\text{OAc})_2$), orange plates, giving a red soln. when heated with H_2O . G. SCHWACH

The so-called balanophorin. A. J. ULRIE *Bull. Jardin botanique Builenzorg* [3], 8, No. 1, 3 pp. (1926); *Chem. Zentr.* 1927, II, 95.—The resinous substance of the wood of the Balanophoraceae, a parasitic plant of Java, and named balanophorin by Göppert in 1841, has been studied by Poleck (*Ann.* 67, 179) and by Simon (*Sitz.-Ber. Kais. Akad. Wiss.* 19, IIb, 1161 (1910); cf. *C. A.* 5, 1919). In a further examn. of this substance, U. chose EtOH instead of Et_2O as an extn. agent, with which 77% of almost pure balanophorin was obtained from the tubers. On a large scale petroleum ether was a good solvent. Sapon. of balanophorin by the method of Leys-Grimme (cf. Rosenthaler, *Grundzüge der chem. Pflanzenunters.* 2 Aufl. 1923), with addn. of C_6H_6 to increase the soly. of the balanophorin, yielded palmitic acid. The alc. in the wax is identical with β -amyrin, m. 195° ; β -amyrin acetate, m. 235° . Balanophorin m. 77° and is therefore identical with β -amyrin palmitate, which has already been synthesized by U. and shown to be the chief component of gondang wax (cf. *Pharm. Weekblad* 61, 1118). It has also been obtained from the wax of cacao leaves (cf. *Ann.* 271, 184 (1892)). Attention is called to the earlier prepn. of candles from the tubers. C. C. DAVIS

Condensation of aldehydes and phenols. III. Nitrated *ms*-phenyldinaphthopyrans. OTTO DISCHENDORFER AND EGON NESITKA. Tech. High School, Graz. *Monatsh.* 50, 16 39 (1928).—The f.-p. curve of $p\text{-O}_2\text{NC}_6\text{H}_4\text{CHO}$ and $\beta\text{-C}_{10}\text{H}_7\text{OH}$, which is given, shows 1 eutectic at 74.5° and 41% $\beta\text{-C}_{10}\text{H}_7\text{OH}$ and a 2nd at 75.5° and 55% $\beta\text{-C}_{10}\text{H}_7\text{OH}$, on mixing the 2 compds in CHCl_3 , C_6H_6 or Et_2O , the orange-yellow mol. compd. sepd., m. 76.5° . $p\text{-O}_2\text{NC}_6\text{H}_4\text{CHO}$ and $\beta\text{-C}_{10}\text{H}_7\text{OH}$ give a f.-p. curve with 1 eutectic at 31.5° and 23% $\beta\text{-C}_{10}\text{H}_7\text{OH}$. Condensation of 1 mol. $p\text{-O}_2\text{NC}_6\text{H}_4\text{CHO}$ and 2 mols. $\beta\text{-C}_{10}\text{H}_7\text{OH}$ in AcOH with concd. HCl gives *ms*-[4-nitrophenyl]dinaphthopyran (I), greenish yellow, m. 318° . Oxidation of I with MnO_2 and HCl , PbO_2 or H_2SO_4 gives *ms*-[4-nitrophenyl]dinaphthopyranol (II), analyzed as the FeCl_3 salt, bright red, m. 290° (decompn.). Werner (*Ber.* 34, 3304 (1901)) believed that, in the oxidation of the NO_2 -free compd., he obtained an anhydride or ether, repetition of the work shows that the compd. is *ms*-phenyldinaphthopyranol. II, in CHCl_3 contg. a little AcCl , gives with HCl the *chloride-HCl*, bright red, gradually losing HCl on standing; the HgCl_2 salt is red with golden luster, m. 253° (decompn.). II with HBr in AcOH , followed by addn. of Br , gives the *perbromide*, red. *Perchlorate*, red with green metallic luster, m. 299 – 301° (decompn.). Heating the FeCl_3 salt with abs. EtOH gives the *Et ether*, m. 243 – 4° ; *Me ether*, m. 263° (decompn.). Reduction of I or II with Zn and AcOH gives the *Ac deriv.* (III), m. 246° of *ms*-[4-acetaminophenyl]dinaphthopyran, m. 253 – 4° (decompn.). The oxidation of III in AcOH-HCl gives *ms*-[4-acetamidophenyl]dinaphthopyranol, m. 270° (decompn.), isolated as the FeCl_3 salt, dark red, m. 243 – 5° ; the HgCl_2 salt, red, m. 200 – 5° ; the *perchlorate*, red with golden luster, m. 260° (decompn.). I (1 g.), warmed with 100 cc. concd. HNO_3 0.75 hr., gives *dinitro-ms* [4-nitrophenyl]dinaphthopyranol, yellow, does not m. 380° ; HCl in Ac_2O , followed by FeCl_3 , gives the *chloride-ferrichloride*, light brown, m. 325° (decompn.); HBr and Br in Ac_2O give the *perbromide*, red, decomp. 260 – 70° ; *perchlorate*, orange-yellow, m. 301° (decompn.). *Dinitro-ms*-phenyldinaphthopyranol, greenish yellow, m. 297 – 8° (decompn.); *chloride-ferrichloride*, orange, m. 260° (decompn.); *perchlorate*, red, m. 288° (decompn.); *perbromide*, orange with golden luster, decomp. on heating. $2,4,6\text{-(O}_2\text{N)}_3\text{C}_6\text{H}_2\text{CHO}$ and $\beta\text{-C}_{10}\text{H}_7\text{OH}$ give an orange-yellow addn. mol. compd. $\text{C}_{17}\text{H}_{11}\text{O}_5\text{N}_3$, m. 153° . *Dehydro-4-dimethylaminobenzal-di- β -naphthol*, greenish yellow, m. 245° , by the action of NaOH

C. J. WEST

The industrial production of perylene. A. CORBELLINI AND G. AYMAR. Reale Univ. Milano. *Giorn. chim. ind. applicata* 10, 196–9 (1928).—An exptl. study was made of various methods proposed for the synthesis on an industrial scale of perylene

(cf. Scholl, Seer and Weitzenböck, *C. A.* 4, 2920), most of which are patents. Following the directions of Hansgirk (Ger. pat. 386,040 (1918)), a 19.3% yield was obtained. On

evapn. the residual soln. deposited a light yellow impure cryst. *compd.*, m. around 150°, probably a reduction product of β -dinaphthol, *viz.*, dinaphthalene oxide (cf. Schoepfle, *C. A.* 17, 2422). The reaction probably involves 2 stages, the initial formation of the *compd.* from β -dinaphthol and PCl_3 , and the formation of perylene from this on distn. The yield of perylene could not be increased by changing the temps. nor by distg. in an atm. of H or of N. The yield by the method of Pereira (Ger. pat. 390,619 and 391,825 (1921)) was 14%, and increasing the temp. and the time did not increase it. Another method of Pereira (Ger. pat. 394,437 (1922)) gave a 16.5% yield of perylene, and changing the temp. and the proportions and concns. of reagents did not increase the yield. By keeping the temp. at 120°, the yield was only 5.7%. With 5 times as much NaCl and of kieselguhr as Na_2CO_3 as a diluent, the yields were still 16.5%. With no diluent but 3.5 times the proportion of Na_2CO_3 , the yield was only 8.5%. Substitution of Na borate for Na_2CO_3 did not alter the yield. A 13.6% yield of perylene was obtained from β -dinaphthol and AlCl_3 , by the method described, but without Na_2CO_3 , a small proportion of dihydroxyperylene also being formed, contrary to Weitzenböck and Seer (*C. A.* 7, 2947). By the method of Marschalk (U. S. pat. 1,593,938), the yield of perylene was 13% and with the method of the Compagnie Générale des Matières Colorantes (Fr. pat. 571,738 and 571,739 (1922)) the yield was 17%. The low yields with all the methods render it very improbable that any of the methods is of promise industrially.

C. C. DAVIS

Preparation and properties of selenophene and certain halogen derivatives of selenophene. HENRY VINCENT AIRD BRISCO AND JOHN BUTTERY PEARL. Univ. of Durham. *J. Chem. Soc.* 1928, 1741-7.— C_2H_2 and Se at about 400° give, in addn. to the condensation products of C_2H_2 , about 15% of *selenophene*, b_{22} 1,109.9–10.1°, f. p. —38°, mol. wt. by Dumas methods 134, in CHBr_3 (f.-p. method) 132.2, in C_6H_6 156 (calcd. 131.2). The vapor pressure is recorded from 25° to 85°, d_{20}^{20} 1.5232; data are also given for 5 other temps. from 15° to 50°; the coeff. of expansion is 3α (15–30°) = 0.001040; 3α (30–50°) = 0.001040; 3α (15–50°) = 0.001045; n_D^{20} 1.568; surface tension (dynes/cm.): 15°, 36.49; 20°, 35.83; 25°, 35.14; parachor at the same temps., 210.6, 210.8, 210.5. Selenophene resembles thiophene in its remarkable stability and chem. inactivity. It forms no picrate or methiodide, is not oxidized by KMnO_4 , is not reduced by Zn and HCl and is only slightly changed by H and N at 250°. No definite *compds.* were isolated with H_2SO_4 or HNO_3 . Br gives 70% of a *tetra-Br deriv.*, m. 102°, slowly decompd. by boiling H_2O ; *tetra-Cl deriv.*, decomp. 87° (25% yield); the latter is not as stable as the Cl deriv.

C. J. WEST

Active constituents of paracoto bark. Synthesis of protocotoin and methylprotocotoin. ERNST SPATH AND HERMANN BRETSCHNEIDER. Univ. Wien. *Monatsh.* 49, 429–37 (1928); cf. *C. A.* 22, 3408.—Details are given of the synthesis of protocotoin (I) from 1,3,5- $\text{C}_6\text{H}_3(\text{OH})_3$ and $\text{CH}_2(\text{O})_2\text{C}_6\text{H}_4\text{CN}$ in Et_2O with ZnCl_2 and HCl, followed by methylation; the alkali-insol portion contains methylprotocotoin. That the free HO group of I is *ortho* to the CO group is shown by condensing with $\text{BrCH}_2\text{CO}_2\text{Et}$, saponig, the ester and heating the resulting acid in vacuum, thus forming 3,5-dimethoxy-3',4'-methyleneedioxy-2-phenylcoumarone, m. 116.5–7.5°.

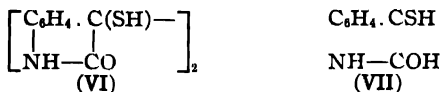

C. J. WEST

Condensation of rhodanic acid with 3-nitroisatin.* Rhodanal- $\Delta^{3,3,5,5}$ -nitrooxindoles. HOWARD A. JONES AND RAYMOND M. HANN. George Washington Univ. *J. Am. Chem. Soc.* 50, 2491–3 (1928).—5-Nitroisatin (2 g.) in 25 cc. AcOH was treated with a mol. quantity of the rhodanic acid and 5 g. fused AcONa and refluxed for 3 hrs. The following *aryl rhodanal- $\Delta^{3,3,5,5}$ -nitrooxindoles*, red, were thus prepd.: *Ph*, m. 260–7°; *o-anisyl*, m. 247°; *p-anisyl*, m. 370°; ψ -*cumyl*, m. 245°; β -*naphthyl*, m. 330°. H_2SO_4 solns. are brilliant red.

C. J. WEST

The chloroisindigotins. A. WAHL AND GEORGE FERICEAN. *Ann. chim.* 9, 277–315 (1928); cf. *C. A.* 22, 1354.—W. and F. study the structure of the chloroisatins and the disulfatides. Treating *o*- $\text{ClC}_6\text{H}_4\text{NH}_2$ with Cl_2CCHO and $(\text{NH}_4\text{OH})_2\text{H}_2\text{SO}_4$ gives the *o*- $\text{ClC}_6\text{H}_4\text{NHCOCH:OH}$. Heating the product with 5 times the wt. of concd. H_2SO_4 at 85° for 6 hrs. gives 7-chloroisatin (I), m. 248°. The *p*- $\text{ClC}_6\text{H}_4\text{NH}_2$ similarly gives 5-chloroisatin (II), m. 242°. I with dioxindole in alc., in the presence of a trace of $\text{C}_6\text{H}_{11}\text{N}$, gives quant. 7-chloroisatide, m. 238°. II with dioxindole gives 5-chloroisatide, m. 255°. I with oxindole (III), in alc. with a trace of $\text{C}_6\text{H}_{11}\text{N}$ gives 7-chloroisatin, m. 182°; II similarly gives 5-chloroisatin, m. 207°. I with III in HOAc with a trace of HCl gives 7-chloroisindigotin (IV), which in HOAc at 100° with Zn gives the white leuco form. II with III gives 5-chloroisindigotin (V), which can be reduced to the leuco form. IV or V in 10 parts of concd. H_2SO_4 gives the *monosulfonic acid deriv.* whose Na, K and Ba salts are isolated. Disulfatide was shown to have structure VI by Laurent but Sauder

believed it had structure VII. Formula VI is favored since the mol. wt. in PhOH checks

this formula and the quantity of S liberated on reduction with H_2S to the leuco form agrees closely. VI is easily sol in NaOH and in $\text{C}_6\text{H}_5\text{N}$. On boiling some III seps. and is characterized by its benzylidene deriv. VI in HOAc at 100° with Zn gives 90% leuco form. 7-Methylisatin in alc. with H_2S gas until decolorized after 10 days gives 80% dimethyldisulfatide; 5-methylisatin gives the corresponding deriv. I in MeOH satd. with H_2S for 6 days gives 7,7-dichloridisulfatide (VIII). II similarly gives the 5,5-di-CI deriv. (IX). Heating VIII in $\text{C}_6\text{H}_5\text{N}$ gives a red ppt. which is 7,7'-dichloroisindigotin (X); on heating in concd. H_2SO_4 X slowly sulfonates and is pptd. with NaCl. At the same time some 7-chlorooxindole (XI), m. 215° , is formed in the $\text{C}_6\text{H}_5\text{N}$ and is concd. in the distn. residues. XI is characterized by its benzylidene deriv., m. 185° . Corresponding reactions occur with II. Heating IX in $\text{C}_6\text{H}_5\text{N}$ gives 5,5-dichloroisindigotin (XII). On reducing with Zn in boiling HOAc XII gives the leuco deriv. XII with 10 parts of concd. H_2SO_4 gives the disulfonate; the Na salt crystallizes with $6\text{H}_2\text{O}$, the K salt with $4\text{H}_2\text{O}$ and the Ba salt anhyd. In the same way as in XI, 5-chlorooxindole, m. $192-5^\circ$, is also obtained and characterized by its benzylidene deriv., m. $204-5^\circ$. D. H. POWERS

Aminothiophenol derivatives. JAKOB POLLAK, EUGEN RIESZ and ZDZISLAW KAHANE. Univ. Wien *Monatsh.* 49, 213-28 (1928).—[4,2-Cl(O₂N)C₆H₃]₂S₂, reduced by Na₂S and NaOH in EtOH to the mercaptan and then treated with ClCH₂-CO₂H, gives 4-chloro-2-nitrophenylthioglycolic acid, m. $209-10^\circ$, with concd. H_2SO_4 this gives 5,5'-dichloro-7,7'-dinitrobisthionaphtheneindigo (D. R. P. 241,910), with H_2O_2 in AcOH there results 4-chloro-2-nitrophenylsulfocetic acid, m. 158° ; with Zn and AcOH, 6-chlorobenzoxetodihydro-1,4-thiazine, light yellow, m. 204° . If the [4,2-Cl(O₂N)C₆H₃]₂S₂ is reduced with Zn in AcOH, there results 4-chloro-2-aminomercaptobenzene II(C) (I), pale yellow, m. 207° ; Cu(OAc)₂ gives a dark bluish green, Pb(OAc)₂ a yellow ppt.; the free base is a dark yellow oil. With HNO₃ the salt gives 5-chlorophenylendiazosulfide, pale yellow, m. 107° . I gives a picryl deriv., yellow, decomp. on heating; if, immediately on adding the picryl chloride, concd. aq. AcONa is added, there results 2,4-dinitro-6-chlorophenothiazine, dark red, decomp. above 280° . Reduction of the disulfide in the presence of Ac₂O and AcONa gives 4-chloroethenylaminothiophenol, m. 78° . [4,2-Cl(H₂N)C₆H₃]₂S₂ and 4,2-Cl(O₂N)C₆H₃SCl in Et₂O give 2-[4'-chloro-2'-nitrobenzenesulfenylamino]-2'-amino-4,4'-dichlorodiphenyl disulfide, green, m. 164.5° ; HCl salt, light green, m. 182° ; the diazo soln gives with β -C₁₀H₇OH a red dye. Further treatment with Cl(O₂N)C₆H₃SCl gives the di-[4'-chloro-2'-nitrobenzenesulfenylamino] deriv., yellow, m. 159° . p -H₂NC₆H₄SH and 4,2-Cl(O₂N)C₆H₃SCl give 4'-chloro-2'-nitro-4-aminodiphenyl disulfide, dark yellow, m. $130-1^\circ$. HCl salt, yellow, m. 205° . Further treatment with Cl(O₂N)C₆H₃SCl gives 4'-chloro-2'-nitrobenzenesulfenyl-4-amino-4'-chloro-2'-nitrodiphenyl disulfide, yellow, m. 187° . Reduction of anilinetrisulfonyl chloride with Zn and concd. HCl gives a trimercaptoaniline, which cannot be isolated pure because of its easy oxidizability; the tripicryl deriv., yellow, explodes on heating; with EtOH-KOH there results a red-brown powder,

AcSC=CH—C S.CMe, which shows none of the properties of a S dye. The reduction of the trisulfonylchloride in the presence of Ac₂O and AcONa gives 3,5-di[acetylmercapto]ethenylaminothiophenol, m. 127° , and a small quantity of the dimercapto deriv., as the HCl salt, m. 180.1° . C. J. WEST

Carbazole-1-carboxylic acid. EDWARD F. BRISQOR and SYDNEY G. P. PLANT. Dyson Perrins Lab., Oxford. *J. Chem. Soc.* 1928, 1990-1.—The proof that the acid obtained by the action of CO₂ on K carbazole at 270° (Ciamician and Silber, *Gazz. chim. ital.* 12, 272 (1882)) or on Mg 9-carbazyl iodide at $265-70^\circ$ (Oddo, *C. A.* 5, 2638) is carbazole-1-carboxylic acid (I) is furnished by boiling a mixt of tetrahydrocarbazole-8-carboxylic acid, S and quinoline for 12 hrs. and purifying the product through the Na salt and the Me ester; the product, m. 268.9° , is identical with the I prepd. by the 1st mentioned method. C. J. WEST

Derivatives of 7,8,9,10-tetrahydro- α,β -naphthocarbazole and of 8,9,10,11-tetrahydro- α,β' -naphthocarbazole. STEPHEN H. OAKESHOTT and SYDNEY G. P. PLANT. Dyson Perrins Lab., Oxford. *J. Chem. Soc.* 1928, 1840-7.—7,8,9,10-Tetrahydro- α,β -naphthocarbazole (I) (*C. A.* 2, 1716) yields a picrate, m. 172° (decompn.); no

cryst. compd. could be isolated from nitration expts. in AcOH or H₂SO₄. Oxidation of I gives α,β -naphthocarbazole. I and EtMgBr give a dark oil, which gives with AcCl the 11-Ac deriv. of I, m. 125°; BzCl gives the 11-Bz deriv., yellow, m. 146–7° (HNO₃ gives a tri-NO₂ deriv., yellow, m. 255° (decompn.)). Electrolytic reduction of I (10 g. I in 100 cc. H₂SO₄ and 100 cc. EtOH at 80°, Pb electrodes and a current of 5 amps) gives 7,8,9,10,14,15-hexahydro- α,β -naphthocarbazole (II), m. 88°; the base develops a mauve color on exposure to the air and gives a blue fluorescence in Et₂O. HNO₃ in AcOH gives a di-NO₂ deriv., yellow, m. 139–40°; boiling II with Ac₂O for 5 min. gives the 11-Ac deriv., m. 132°; 11-Bz deriv., m. 148–9°. 8,9,10,11-Tetrahydro- α,β' -naphthocarbazole (III), m. 137°, yields a black picrate, m. 194° (decompn.); no nitro derivs could be obtained. Oxidation of III gives α',β' -naphthocarbazole, m. 134–5°. Boiling III with Ac₂O contg. a little H₂SO₄ gives a C-acetyl-7-acetyl deriv., greenish yellow, m. 185°, with dil. EtOH-KOH this gives the C-Ac deriv., yellow, m. 213° (oxime, pale yellow, m. 213–6°); with a much shorter reaction time (5 min. instead of 45 min.), there results the 7-Ac deriv., m. 162°; this is more conveniently prepd through the Grignard reaction as described for I; HNO₃ in AcOH gives a NO₂ deriv., bright yellow, m. 222°. 7-Bz deriv. of III, yellow, m. 139°; NO₂ deriv., yellow, m. 208–9°. III is not easily reduced electrolytically but red P and HI give 8,9,10,11,12,15-hexahydro- α,β',β' -naphthocarbazole, b₁₀ 198–202°; HCl salt, buff colored, m. 265° (sublimation) 7-Ac deriv., m. 120°, 7-Bz deriv., m. 131°. The hexahydro derivs. are most likely the *cis*-forms.

C. J. WEST

Condensation of hexahydrocarbazole and of tetrahydropentindole with cyclopentanone cyanohydrin. SYDNEY G. P. PLANT and DOROTHY MAY LYDDON RIPPON. Dyson Perrins Lab., Oxford. *J. Chem. Soc.* 1928, 1906–13.—Hexahydrocarbazole (I), cyclopentanone (II) and KCN in AcOH-H₂O give 1-[9'-hexahydrocarbazyl]-1-cyanocyclopentane (III), m. 76°. Attempts to hydrolyze III with concd. HCl or EtOH-HCl gave only I and II; allowed to stand 2 days in concd. H₂SO₄, III gave the 1-carboxamide, m. 160°; this was unchanged after boiling with EtOH-KOH for 4 hrs. or heating with 40% H₂SO₄; boiling with concd. HCl gives I as does heating with powd. KOH at 180–200°. 1-Anilino-cyclopentane-1-carboxylic acid nitrosoamine and II in glacial AcOH, heated to 50° and reduced with Zn, give 25% of 1-[9'-tetrahydrocarbazyl]-cyclopentane-1-carboxylic acid, m. 184°. When warmed with 60% H₂SO₄, when distd. or when heated with solid KOH, it dissociates into tetrahydrocarbazole and Δ^1 -cyclopentene-1-carboxylic acid, m. 119°. Electrolytic reduction of dihydropentindole gives the tetrahydro deriv., b₁₆ 152°, m. 21°. Ac₂O gives the 8-Ac deriv., m. 78°; 8-Bz deriv., m. 86°; picrate, yellow, m. 159°. MeI gives the 8-Me deriv., b₁₅ 136–7° (picrate, yellowish green, m. 116°; methiodide, m. 189°) 1-[8'-Tetrahydropentindyl]-1-cyanocyclopentane, m. 51° (picrate, yellow, m. 126°), with concd. H₂SO₄ this gives the 1-carboxamide, m. 130°; the amide could not be hydrolyzed to the corresponding acid.

C. J. WEST

Diketones. I. The reaction between 4-phenylsemicarbazide and acetylacetone. ALVIN S. WHEELER and R. D. NORTON. Univ. North Carolina. *J. Am. Chem. Soc.* 50, 2488–90(1928)—PhNHCONHNH₂ (9.5 g) and 4.6 g. Ac₂CH₂ in EtOH give 8.5 g. 1-phenylcarbamyl-3,5-dimethylpyrazole, m. 69°; 4-Br deriv., m. 100–1°. The structure was proved by boiling with EtOH, giving PhNHCO₂Et and 3,5-dimethylpyrazole and with H₂O, giving CO₂, PhNHCONHPh and 3,5-dimethylpyrazole. The Br deriv. and H₂O give 3,5-dimethyl-4-bromopyrazole.

C. J. WEST

Relation between atomic grouping and specific affinity. VII. Capacity of salt formation in imidazole derivatives. FRITZ FEIGL and HUGO GLEICH. Univ. Wien. *Monatsh.* 49, 385–400(1928).—Benzimidazole yields a Hg salt, C₇H₆N₂HgCl, a Cu salt, 4C₄H₁₀N₄Cu.NH₃.H₂O, a Cd salt, C₄H₁₀N₄Cd, a Co salt, bluish violet, C₄H₁₀N₄Co, a Zn salt, C₄H₁₀N₄Zn or 4C₄H₁₀N₄Zn.NH₃.H₂O. Ethenyl-*o*-phenylenediamine yields a Ag and a Hg salt. Phenylbenzimidazole yields a Ag and a Hg salt. *N*-Phenylbenzimidazole does not yield metallic salts. *N*-Benzylbenzimidazole, m. 105°, also does not give metallic derivs; nor does *N*-methyltolimidazole. Phenoxymethylenebenzimidazole, m. 162°, gives a Ag and a Hg salt. Ethoxymethylenebenzimidazole, m. 152° (Ag and Hg salts). Methoxymethylenebenzimidazole, m. 137° (Ag and Hg salts). *o*-Phenyleneurea and chlorobenzimidazole do not yield metallic salts. Anhydrooxanilide gives both Ag and Hg salts; amarine does not give a Hg salt. Lophine gives a Ag but not a Hg salt. *o*-Aminobenzylaniline does not yield a Ag salt, nor does diphenylethanamidine; *m*-tolimidazole and 2-chlorotolimidazole also give metallic salts (qual. investigated only). 1,2-Naphthimidazole gives Ag and Hg salts. Glyoxaline yields a Zn and a Co salt, but no ppt. was obtained with Cu or Cd. VIII. Several addition compounds of thallium dienolic salts with CS₂. FRITZ FEIGL and ERNST BACKER. *Ibid* 401–12.—Kurovskii (*C. A.* 4, 2464) proposed the reaction of Tl acetyl acetate with CS₂ as a test for small quantities of CS₂.

Salts of Ag, Cu, Pb and Hg are not reactive towards CS_2 ; Tl acetate or other org. compds. do not give the reaction, so that the reaction is dependent on the union of Tl with an enolic salt. On the other hand, other S-contg. compds. give addn. products with Tl acetylacetate. The reaction is now extended to other enolic derivs. of Tl. The Tl compd. of AcCHMeAc gives no compd. with CS_2 . $\text{MeCH(OH)CH}_2\text{Ac}$ gives no Tl compd. nor does CS_2 react with a mixt. with a Tl salt. AcCH_2Bz gives a light yellow Tl salt, which yields a cinnabar-red compd. with CS_2 , of the formula $\text{C}_{11}\text{H}_9\text{O}_2\text{S}_2\text{Tl}_2$; the anil does not react with Tl or CS_2 . AcCHMeBz gives a light yellow Tl compd., which does not react with CS_2 . CH_2Bz gives a yellow Tl compd., whose carmine-red CS_2 compd. has the formula $\text{C}_{16}\text{H}_{16}\text{O}_2\text{S}_2\text{Tl}_2$. $\text{AcCH}_2\text{CO}_2\text{Et}$ does not give a Tl compd., but with Tl_2CO_3 and CS_2 there results the yellow compd., $\text{C}_7\text{H}_5\text{O}_3\text{S}_2\text{Tl}_2$. $\text{BzCH}_2\text{CO}_2\text{Et}$ also does not give a Tl deriv., but an orange-red CS_2 compd., $\text{C}_{12}\text{H}_{10}\text{O}_3\text{S}_2\text{Tl}_2$, may be obtained as above. $\text{CH}_2(\text{CO}_2\text{Et})_2$ does not react with Tl or CS_2 ; neither does $(\text{AcCHCO}_2\text{Et})_2$. $\text{AcCH}_2\text{COCO}_2\text{Et}$ gives a yellow Tl deriv., which, however, does not react with CS_2 ; the same is true of $\text{BzCH}_2\text{COCO}_2\text{Et}$ and $\text{EtO}_2\text{CCOCH}_2\text{CO}_2\text{Et}$. Ac_2 and $(\text{AcCH}_2)_2$ do not react with Tl. The structure of the CS_2 compds. is discussed. C. J. WEST

Curtius rearrangement of carbamyl azides; formation of indazolones and dimolecular carbonylhydrazines. R. STOLLÉ AND N. MERKLE. Univ. Heidelberg. *J. prakt. Chem.* **119**, 275-8 (1928); cf. *C. A.* **21**, 2899. —Treating $\text{PhN}(\text{CON}_2)\text{N}:\text{CHC}_6\text{H}_4\text{Cl}$ in EtOH with NH_4OH and warming 15 min on the H_2O bath gives *o*-chlorobenzal-1-phenyl-2-semicarbazide, m. 181° . Heated with FeCl_3 in EtOH this yields 1-phenyl-3-*o*-chlorophenyl-5-hydroxy-1,2,4-triazole, m. 188° . C. J. WEST

Silver and mercury salts of aminobenzothiazole. FRITZ FEIGL AND ARNOLD DEUTSCH. Univ. Wien. *Monatsh.* **49**, 413 6 (1928) —Aminobenzothiazole (I) and neutral AgNO_3 soln. give a cryst. ppt. of $\text{AgC}_7\text{H}_6\text{N}_2\text{S}$; if this ppt. is dissolved in concd. NH_4OH and warmed on the H_2O bath there gradually ppts the yellow $\text{Ag}_2\text{C}_7\text{H}_4\text{N}_2\text{S}$. Aq. $\text{Hg}(\text{NO}_3)_2$, treated with a large excess of I in the presence of AcONa and heated 1 hr on the H_2O -bath, gives the deep yellow $\text{HgC}_7\text{H}_4\text{N}_2\text{S}$; I and HgCl_2 in EtOH give the addn. compd. $\text{I} \cdot \text{HgCl}_2$, turns pure yellow on heating with H_2O ; aq. HgCl_2 , I and AcONa , warmed on the H_2O bath, give $\text{HgClC}_7\text{H}_3\text{N}_2\text{S}$, yellow; aq. $\text{Hg}(\text{NO}_3)_2$, an insufficient quantity of I and AcONa , warmed on the H_2O bath, give $\text{Hg}_2\text{ONO}_3\text{C}_7\text{H}_5\text{N}_2\text{S}$. I in dil. HCl and I-KI give the compd. $\text{C}_7\text{H}_6\text{N}_2\text{S} \cdot \text{HI} \cdot \text{I}_2$. C. J. WEST

Rotenone, the physiologically active constituent of Derris elliptica. A. BUTENANDT in part with O. LINSERT AND D. BOTSCHWAR. Univ. Göttingen. *Ann.* **464**, 253-77 (1928); cf. Takei, *C. A.* **22**, 2941. —This work is published because of the appearance of the work of T. B. confirms the formula, $\text{C}_{23}\text{H}_{20}\text{O}_6$, suggested by T. for rotenone (I), which m. 163° , b₀ $210-20^\circ$; oxime, m. 249° ; hydrazone, m. 258° (decompn.) (70% yield); these derivs. result in slightly acid soln., are insol. in alkali and give no color with FeCl_3 . If I is treated with ketone reagents in the presence of alkali, derivs. of the CO_2 groups are obtained isomeric with the above but possessing phenolic characters, being sol. in alkali, and giving characteristic colors with FeCl_3 ; the *isoxime*, m. 230° , gives a bluish black color with FeCl_3 ; *isohydrazone*, m. 229° , gives a blue-green color with FeCl_3 ; *isophenylhydrazone*, m. 203° , gives a brownish yellow color with FeCl_3 . Catalytic reduction (1 mol. H) gives the dihydro deriv. (II), m. $214-6^\circ$ (20% yield); if the reduction is continued until 3-3.5 mols. H are used, there results *dihydrodesoxyrotenone*, m. 168° (70% yield), formed by the reduction of a CO group; this does not react with MeMgI , cannot be acetylated and does not yield a ketone deriv.; it dists. undecompd. in high vacuum at $220-30^\circ$ and is not changed by heating with 10% EtOH-NaOH at $130-40^\circ$. Catalytic reduction of I in EtOH-NH_3 gives a compd. $\text{C}_{23}\text{H}_{26}\text{O}_6$, m. 206° , which gives a pale blue color with FeCl_3 but does not contain a CO group. I and EtNO in AcOH give 60-50% of rotenone (III), m. $298-300^\circ$ (decompn.), $[\alpha]_D^{25} -3.5^\circ$ (CHCl_3); this also results by the oxidation of I with CrO_3 in AcOH ; *dihydrazone* (?), m. 242° ; reduction of III gives *perhydropyrenone*, $\text{C}_{23}\text{H}_{26}\text{O}_6$, pale yellow, m. $265-7^\circ$ (decompn.) (20% yield); *Ac deriv.*, yellowish green, m. 245° . With alc. KOH , III gives a HO acid, m. 250° , whose *Me ester*, m. $146-7^\circ$. Complete oxidation of I with KMnO_4 in C_6H_6 gives only $(\text{CO}_2\text{H})_2$; other oxidizing agents as well as alc. NH_3 give *dehydrorotenone* (IV), light yellow, dists. undecompd. at $240-50^\circ$ in a high vacuum, m. 218° ; *oxime*, m. 200° . Alc. KOH gives with IV a *hydroxyketo acid*, $\text{C}_{23}\text{H}_{24}\text{O}_8$, m. 152° ; FeCl_3 gives a red-violet color; *Ac deriv.*, m. 112° ; *oxime*, m. 140° (slow decompn.); *dihydro deriv.*, m. 168° ; FeCl_3 gives no color. Tubaic acid gives an *Ac deriv.*, m. 133° ; a *Me ester*, m. 48° ; and a *dihydro deriv.*, m. 166° . Reduction of I with Zn and KOH in EtOH gives *derritol* (V), $\text{C}_{23}\text{H}_{26}\text{O}_6$, deep yellow, m. 161° (32% yield); MeMgI gives 2 mols. CH_4 ; the by-product of the reduction is a compd., $\text{C}_{23}\text{H}_{24}\text{O}_6$, termed *rotenol*, m.

115–20°, distd. in high vacuum at 200–10° (dihydro deriv., m. 131°); it does not give an Ac deriv. nor does it react with ketone reagents. **V** gives an *oxime*, m. 191–2°. Distrn. of **V** at 0.06 mm. and 220–5° gives 20–30% of a *compd.*, $C_{21}H_{20}O_6$, m. 157°; *Ac deriv.*, m. 146°, whose *dihydro deriv.*, m. 131°. Alk. reduction of **II** gives the same dihydro deriv. of rotenol. A formula for **I** must explain its optical activity, its indifference towards $MeMgI$, $FeCl_3$, CH_2N_2 and Ac_2O , the reduction of Fehling and Tollen solns., the formation of 2 structurally different oximes and hydrazones, the ease of dehydrogenation to a dehydro deriv., which takes up 2 mols H_2O to form a mono- CO_2H acid; the decompn. of **I** with Zn and alkali to **V**, which contains 2 C atoms less than **I**, the alkali degradation of **I** to tubaic acid and the formation of a mono- CO_2H acid on reduction in NH_3 .

C. J. WEST

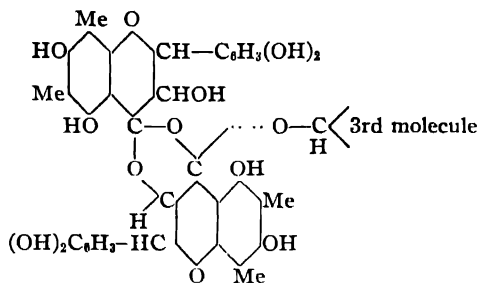

Spectrography of the compounds of the flavone series. I. Spectrographic investigations of some derivatives of flavones, flavonols and styrylchromonols. SHIZUO HATTORI. Imperial Univ. Tokyo. *Acta Phytochim* (Japan) **4**, No. 1, 41–61 (1928).—The mono-HO derivs. of the flavones, flavonols and styrylchromonols were used to study the influence of substitution on the absorption spectra. Of the 7 theoretically possible flavone isomers all but 8-hydroxyflavone could be synthesized. Several of the isomers gave only 1 absorption spectrum, others gave 2 or 3. The position and intensity of the spectra varied greatly. The monohydroxyflavones were grouped into (1) those with the OH group attached at the Ph nucleus and (2) those with the OH at the benzopyrone nucleus. The 2nd group seemed to show greater optical activity, with the exception of 4-hydroxyflavone, which gave marked optical properties. The optical equivalency of the MeO or the EtO group with the HO, and the same with the methylenedioxy group with 2 adjacent HO or MeO groups was established. Acetylation causes the disappearance of the auxochromatic influence of the HO group. Absorption spectra curves are given for 21 compds. **II. Synthesis of two new flavone glucosides. Spectrographic influence of the sugar attachment and acylation.** *Ibid* 63–75.—The new flavone glucosides are 7-glucosidoxyflavone, $ROC_6H_4OC(Ph)CH_2CO$ (I) and 4'-glucosidoxyflavone, $C_6H_4OC(C_6H_4OR):CH.CO$ (II) ($R = C_6H_4O$). Both are ob-

tained from their corresponding flavones by converting them first to tetraacetylglucosidoxyflavones (treatment with acetobromoglucose in acetone), which are dissolved in MeOH. NH_3 , dried over soda lime, is introduced into these solns. After about 10 min. of NH_3 treatment crystals of the glucoside form. **I** is obtained by crystn. from MeOH in fine yellow needles easily sol. in alc., $AcOEt$ and acetone on heating, but sepg. out on cooling in a gelatinous form. It m. 255°, $[\alpha]_D^{25} -160.42^\circ$ in abs. MeOH. **II** forms colorless needle crystals from MeOH, m. 252–4°, insol in ether, benzene, $CHCl_3$, CS_2 and in cold alkalis and NH_4OH , sol. in hot H_2O , alc., acetone and warm $AcOEt$ and MeOH. It is *l*-rotatory but the sp. rotation could not be detd. A comparison of the absorption curves of 7-propionyl-, and 7-capronyl oxyflavones indicates that both new derivs. of 7-hydroxyflavone are similar to 7-hydroxyflavone. From this it was concluded that the anti-auxochrome action shows no characteristic of the Ac group but is due to the EtCO and AmCO groups and probably also to higher aliphatic acyl groups. Acetylation of the free HO groups of a glucoside and comparison of their absorption curves with the acetates of 7 isomeric monohydroxyflavones, shows that the attachment position of the sugar is at the 1st C atom. In the flavonol glucosides the sugar residue is always attached at the 3rd C atom. Similar absorption curves are noted between chrysin and toringin and between apigenin and the glucosides apiin and acacin; this shows further the equivalency of the glucosidoxy and HO groups in relation to light absorption.

Cacao red. II. A. HEIDUSCHKA AND B. BIENERT. Tech. Hochschule, Dresden. *J. prakt. Chem.* **119**, 199–208 (1928); cf. *C. A.* **22**, 595.—The method of prepn. of the dyestuff has been shortened, in that the Pb ppt is directly decompd. with $EtOH-HCl$; a new formula, $(C_{34}H_{31}O_{13})_x$, is proposed, based upon analyses of certain derivs. Distrn. with Zn gives a small quantity of mesitylene. The action of alk. H_2O_2 gives a product contg. 66.91% C and 7.28% H; on standing it slowly takes up O. The *nona-Ac deriv.*, decompg. 210–5°, is an amorphous brownish yellow powder, which is decompd. by warming with KOH. The *nona-Bz deriv.*, pale yellow, amorphous powder, decomp. 219–20°, which is insol. in cold KOH but is easily sapond. with warm alkali. Me_2SO_4 gives a *hepta-Me deriv.*, light brown, amorphous powder, decompg. 213–6°; a 2nd fraction appears to be a mixt. of the tri- and penta-Me derivs. $PhNHNH_2$ gives a brown compd., which is split by boiling with $EtOH-HCl$. The dye in $EtOH$ gives a dark brown ppt. with $EtOK$, a dark brownish green ppt. with $NaOEt$; $EtOH-AcOK$ partially ppts. the dye from

EtOH as a brown ppt. It is believed that the dye has as its parent substance 3',4',3,5,7-pentahydroxy-6,8-dimethyl-2,3-dihydroflavone and that it has the following structure:

C. J. WEST

Preparation of some pyrrolidine derivatives. F. B. LAForge. U. S. Dept. Agr. *J. Am. Chem. Soc.* **50**, 2471-7 (1928).—A no. of pyrrolidine derivs. have been prepd. with reference to their chem. relation to nicotine and tested as contact insecticides. AcCHNaCO₃I₂t (50 g.) and 41 g. *p*-MeC₆H₄OCH₂CH₂Br in EtOH give 25 g. of *Et β-p-cresoxyuretoacetate*, b. 202-4°; hydrolysis with NaOH-EtOH gives *γ-p-cresoxypropyl Me ketone*, b. 175°; semicarbazone, m. 158°; and *γ-p-cresoxybutyric acid*, m. 84-5°. The *ketoxime*, m. 54°, is reduced by Na-Hg in 95% EtOH and AcOH to *1-p-cresoxy-4-aminopentane*, b₇₆₀ 280-3°; in the air it forms a cryst. carbonate, the HCl salt is somewhat hygroscopic. Heating with HCl at 100° gives *α-methylpyrrolidine*, b. 94-7°. *1-Phenyl-1-methylaminobutane*, b₃₃ 117-8°, b₇₆₅ 220°, results in 20 g. yield from 32 g. of the Br deriv. *α-Phenyl-N-methylpyrrolidine (I)* could not be obtained from this. Br(CH₂)₃CHBrPh, treated with MeNH₂, gives a *compd.* C₁₁H₁₃N, b₇₇₀ 209-16°, which is not **I**, since it is unsatd. Benzoyltrimethylene bromide and MeNH₂ give benzoyltrimethylene (any base behaves the same way) and *phenylmethylpyrrolidine (?)*, b₃₄ 134-9°; this could not be reduced. *β-p-Cresoxyethyl benzoylacetate*, b₃ 240-50°, *γ-p-cresoxypropyl Ph ketone*, b₈ 250-60°, m. 63°; *ketoxime*, m. 75°; reduction gives *1-p-cresoxy-4-amino-4-phenylbutane*, whose HCl salt, needles, heated with HCl for 20 hrs, gives *1-phenyl-1-amino-4-chlorobutane-HCl*, m. 200-5° (decompn.); with concd. KOH this gives *α-phenylpyrrolidine*, b₁₆₇ 236-8°; MeI gives the *N-Me deriv.*, b₁₆₀ 225-7°. C. J. W.

Preparation and properties of some new derivatives of pyridine. F. B. LAForge. U. S. Dept. Agr. *J. Am. Chem. Soc.* **50**, 2477-83 (1928).—Details are given for the prepn. of nicotinic acid amide, *β*-pyridine cyanide, *β*-pyridyl Me ketone and the *ketoxime*, reduction of the oxime with Zn and EtOH-AcOH gives *β-pyridylethylamine*, b₇₆₅ 219-21°; *picrate*, m. 186-7°. EtI gives the *N-Et deriv.*, b₇₇₃ 223-6°. *β*-Pyridine cyanide and PrMgI give *β-pyridyl Pr ketone*, which could not be obtained pure by distn. (b. 240-8°); the phenylhydrazone, m. 129-30° (literature gives 182°), *semicarbazone*, m. 169-70°; with concd. HCl, the hydrazone gives an *indole deriv.*, C₁₁H₁₁N₃, m. 158°; reduction of the hydrazone gives *1-β-pyridylbutylamine*, b. 247-51°; *N-Me deriv.*, b₇₆₀ 244-7°. Although these *compds.* are chem. very similar to nicotine, they are, nevertheless, of low toxicity to insects. Metanicotine, nicotyrine and dihydrometanicotine were of a high order of toxicity, the 1st mentioned being only slightly below nicotine.

C. J. WEST

Preparation of *α*-, *β*- and *γ*-benzylpyridines. F. B. LAForge. U. S. Dept. Agr. *J. Am. Chem. Soc.* **50**, 2484-7 (1928).—The method of Chichibabin for the prepn. of *α*- and *β*-benzylpyridine has been simplified by omitting the 1st treatment with NaOH and Et₂O extn., the reaction mixt. being poured directly into H₂O; the *α*-deriv. may be sepd. by fractional crystn. of the picrates. The *γ*-base was obtained by oxidation of the mixt. to the ketone and reduction of this by Zn-Hg in 10% HCl; the *Zn salt*, m. 161°. *β*-Benzoylpyridine is conveniently prepd. from the cyanide and PhMgBr; reduction of the oxime gives *β-pyridylphenylmethylamine*, b₇₆₀ 329-31°; NaNO₂ and HCl give the corresponding carbinol, which is reduced by HI to *β*-benzylpyridine. C. J. WEST

Synthesis of pyridine derivatives. ERNST SPATH and GEORGE BURGER. Univ. Wien. *Monatsh.* **49**, 265-70 (1928).—Condensation of BzCH₂CHO, which probably reacts as PhC(OH).CHCHO, with H₂NCMe:CHCO₂Et, which probably reacts as HN:CMech₂CO₂Et, gives the *Et ester*, b₂ 160-1°, m. 46-6.5° (*chloroplatinate*, m. 196°), of *2-methyl-6-phenylpyridine-3-carboxylic acid*, m. 186° (*HCl salt*, m. 288° (decompn.)), whose constitution was established by splitting off CO₂, giving 2,6-C₆H₄NMePh, and by

oxidation with KMnO_4 to 6-phenylpyridine-2,3-dicarboxylic acid, m. 148–50°, which, upon dry distn., yields $\alpha\text{-C}_6\text{H}_4\text{NPh}$.

C. J. WEST

A new method for the preparation of 2,2'-dipyridyl. J. P. WIBAUT AND J. OVERHOFF. Univ. Amsterdam. *Rec. trav. chim.* 47, 761–3 (1928).—On heating $2\text{-C}_6\text{H}_4\text{NBr}$ or $2\text{-C}_6\text{H}_4\text{NI}$ with finely divided Cu in *p*-cymene at about 180°, 2,2'-dipyridyl is formed, the yield being greater with the Br than with the I compd., while the Cl compd. does not react at all under these conditions. With $2\text{-C}_6\text{H}_4\text{NBr}$ a 60% yield of 2,2'-dipyridyl is obtained together with a small quantity of $\text{C}_6\text{H}_5\text{N}$. The best way to carry out the prepn. is to boil 40 g. $2\text{-C}_6\text{H}_4\text{NBr}$, 75 cc. *p*-cymene and 80 g. Kahlbaum "Naturkupfer C" during 2 hrs., it being advisable to crush the cake of Cu powder after half an hr. In order to obtain the 2,2'-dipyridyl from the reaction product, the *p*-cymene is distd. from it with steam after acidification with HCl and then the 2,2'-dipyridyl after having added a large excess of alkali. The following consts. were found for 2,2'-dipyridyl: b. 273–5°, setting point 70.1°, m. p. of the picrate 157–8.5°.

C. F. VAN DUIN

Natural rotation of polarized light by optically active bases. I. Influence of solvents upon the rotatory power of *d*- α -pipecoline and its hydrochloride. WOLFGANG LEITHE. Univ. Wien. *Monatsh.* 50, 40–7 (1928).—The following values for $[\alpha]_D^{15}$ (*c* about 10) are reported for *d*- α -pipecoline (36%) in various solvents. piperidine, 37°; hexane, 35.7°; Et_2O , 35.3°; C_6H_6 , 30°; AcOEt , 30°; Me_2CO , 29.3°; $\text{C}_6\text{H}_5\text{N}$, 26.6°; CCl_4 , 20.4°; CHCl_3 , 18.7°; EtOH , 9.3°; MeOH , 8.7°; H_2O , 7.5°; AcOH , -4.2°; for the HCl salt, H_2O , -3.1°; MeOH , -3.4°; EtOH , -4.2°; CHCl_3 , -1.5°.

Decahydroquinoline derivatives. III. The Hofmann degradation of decahydroquinoline. SHIN-ICHIRO FUJISE. *Sci. papers Inst. Phys. Chem. Research* (Tokyo) 8, 185–95 (1928).—Thirty g. trans-*N*-methyldecahydroquinoline-MeI treated with excess Ag_2O , filtered, cvapd. and distd. under ordinary pressure gave 9.6 g. (36% of theory) of trans-*o*-dimethylaminoallylcyclohexane (I), which purified through the picrate, b. 206°. I absorbs Br_2 in AcOH , reduces AuCl_3 . Picrate, m. 101–2°. Hydrogenation of I gave trans-*o*-dimethylaminopropylcyclohexane (II), b. 207°, which absorbed no Br_2 . Picrate, m. 114.5–5.5°. II. HIAuCl_4 . II. MeI (III), m. 185°. II. MeCl AuCl_4 , m. 91.5°. 15 g. of III distd. with Ag_2O as above gave 3.5 g. of Δ^2 -propylcyclohexene (?), b. 154.5–5.5°, which does not give a solid nitroschloride, Me_3N and II. 17 g. cis-*N*-Methyldecahydroquinoline-MeI distd. with Ag_2O gave 5.7 g. of cis-*o*-dimethylaminoallylcyclohexane (IV), b. 213–4°. IV absorbs Br_2 in AcOH . Picrate, m. 173°. Hydrogenation of IV gave cis-*o*-dimethylaminopropylcyclohexane (V), b. 214–6°. Picrate, m. 173°. V. HIAuCl_4 , m. 132°. Methiodide, m. 186°. Methochloride. AuCl_4 , m. 130°. D. D.

Synthesis of acridinic acid (quinoline-2,3-dicarboxylic acid). GEORG KOLLER AND ELSE STRANG. Univ. Wien. *Monatsh.* 50, 48–50 (1928).—Condensation of 4.2 g. $o\text{-H}_2\text{NC}_6\text{H}_4\text{CHO}$ and 4.6 g. $\text{EtO}_2\text{CCl}_2\text{COCO}_2\text{Et}$ in 64 cc. abs. EtOH by 0.04 g. KOH (1 week at room temp.) gives 2.5 g. of the *d*-*Et* ester, m. 54–5°, of acridinic acid, identical with the synthetic ester. The free acid is obtained by sapon.

C. J. WEST

Synthesis of acridone and acridine. GEORG KOLLER AND ERICH KRAKAUER. Univ. Wien. *Monatsh.* 50, 51–4 (1928).—Heating the ζ a salt of $o\text{-H}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ at 340° gives a compd. $\text{C}_{26}\text{H}_{22}\text{ON}_4$, possibly $\text{H}_2\text{NC}_6\text{H}_4\text{C}(\text{NC}_6\text{H}_4\text{COC}_6\text{H}_4\text{NH}_2)_2\text{C}_6\text{H}_4\text{NH}_2$, m. 233°; distn. with Zn dust in a stream of H gives acridine; heating with concd. HCl 16 hrs. at 170° gives acridone.

C. J. WEST

Steric hindrance in reactions of substituted quinoxalines. GEORGE MACDONALD BENNETT AND GERVASE H. WILLIS. Univ. of Sheffield. *J. Chem. Soc.* 1928, 1960–75.—The Me groups of 2,3-dimethylquinoxaline (I) are each in the α -position with respect to 1 N atom of the heterocyclic nucleus but each at the same time in the β -position with respect to the 2nd N atom; these Me groups might therefore be of the non-reactive or at least of a less reactive type, as regards aldehyde and other reagents. The observation that both Me groups have a high reactivity was of sufficient interest to warrant a detailed study. The reaction of I proceeds easily with most substituted BzH , including those with a NO_2 or Cl in the *o*-position, yet the 2nd stage of the reaction is inhibited when an *o*-MeO is present. The explanation is to be found in the polar character of the various atoms and groups and in the forces of attraction and repulsion which arise between them. 2-Benzylquinoxaline, dark oil; picrate, yellow, m. 117°. Ph β -methoxy-*p*-chlorostyryl ketone, b_{18} 238°, m. 45°; with HBr in AcOH this gives Ph *p*-chlorobenzyl diketone, m. 85°, which condenses with $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$ to give 2-*p*-chlorobenzyl-3-phenylquinoxaline, m. 142°. Ph β ,3-dimethoxystyryl ketone, b_{18} 245°; HBr gives a compd., m. 175–80°, which was not the expected diketone. The quinoxalines were condensed with aldehydes by boiling with 5–6 mols. Ac_2O . 2-[2,4-Dinitrostyryl]quinoxaline, m. 219–20° (decompn.); 80% yield after 1 hr. 2-*o*-Nitrostyrylquinoxaline, pale yellow, m. 156°

(78% after 3 hrs.); *m*-NO₂ deriv., m. 199.5° (68% after 4 hrs.); *p*-NO₂ deriv., pale yellow, m. 200° (65% after 0.75 hr.). I and BzH after 2 hrs. give 50–70% of 2,3-distyryl-quinoxaline, yellow, m. 190.5°. 2-Methylenedioxydistyryl-3-methylquinoxaline, lemon-yellow, m. 150° (20%); 2,3-di[methylenedioxydistyryl]quinoxaline, yellow, m. 208° (30% yield) 2,3-Di-[*m*-nitrostyryl]quinoxaline, yellow, m. 237° (10% yield); the sol. fraction consisted of 2-*m*-nitrostyryl-3-methylquinoxaline, m. 184° (1–2% yield). The corresponding *p*-MeO deriv., yellow, m. 163° (10% yield), and yellow, m. 122.5° (10% yield). 2,3-Di-[*m*-methoxydistyryl]quinoxaline, yellow, m. 126° (10% yield); 2-*o*-methoxydistyryl-3-methylquinoxaline, yellow, m. 112° (1–2% yield) 2,3-Di-[3,4-dimethoxydistyryl]quinoxaline, yellow, m. 208° (10% yield); 2,3-di[β-furylvinyl]quinoxaline, yellow, m. 169° (5% yield). 2,3-Di-[*o*-nitrostyryl]quinoxaline, m. 194.5° (80% yield); the *p*-NO₂ deriv., deep yellow, m. 288° (decompn.) (75% yield). 2-[2,4-Dinitrostyryl]-3-methylquinoxaline, orange-yellow, m. 224–5° (decompn.). The *m*-*p* curve of this with 2,4-(O₂N)₂C₆H₃CHO is given; a compd., m. 96–7°, formed from the 2 compds. contains 2 mols. aldehyde to 1 mol. of base. 2,3-Di-[2,4-dinitrostyryl]quinoxaline, brown, m. 295–7° (decompn.) (75% yield). 2-[2,4,6-Trinitrostyryl]-3-methylquinoxaline, brown, m. 250–1° (decompn.) (25% yield). 2,3-Di-[*o*-chlorostyryl]quinoxaline, yellow, m. 189.5° (60% yield); *m*-Cl isomer, yellow, m. 149° (30% yield). *p*-Cl isomer, m. 218° (60% yield); *o*-I deriv., pale yellow, m. 179° (40% yield). 2,3-Distyryl-6-methylquinoxaline, yellow, m. 193° in 81% yield from 2,3,6-trimethylquinoxaline and BzH 2,3-Di-[methylenedioxydistyryl] deriv., m. 168° (10% yield). 2,3-di-[3,4-dimethoxydistyryl] deriv., orange-yellow, m. 205° (5% yield); 2,3-di-[*p*-methoxydistyryl] deriv., yellow, m. 136° (15% yield); 2,3-di-[*m*-nitrostyryl] deriv., m. 244.5° (10% yield); 2,3-di-[2,4-dinitrostyryl] deriv., orange-yellow, m. 251–5° (decompn.) (80% yield). 2-*p*-methoxydistyryl-3,6-dimethylquinoxaline, yellow, m. 116° (1–2%), 2-*m*-NO₂ deriv., m. 165° (1–2% yield) 3-Phenyl-2-methylquinoxaline and BzH give 90% of 2-styryl-3-phenylquinoxaline, pale yellow, m. 149°; 2-*p*-NO₂ deriv., bright yellow, m. 233°; 2,4-dinitro deriv., yellow, m. 215°. 2-Benzylquinoxaline and *p*-O₂NC₆H₄CHO give 2-[β-phenyl-*p*-nitrostyryl]-quinoxaline, pale yellow, m. 149°. Quinoxalinoocyclopentane and BzH give 40% of the dibenzylidene deriv., brown, m. 213°. *di-p*-nitrobenzylidene deriv., yellow, decompn. 268–70° (85% yield). 2,4-(O₂N)₂C₆H₃CHO and quinaldine give 60–80% of 2-[2,4-dinitrostyryl]quinoline, pale yellow, m. 200°; *N*-Me deriv., bright yellow, m. 198°; 3-Me deriv., brown, m. 257°. 2-Styryl-3-methylquinoline, m. 102° (50% yield). I and (CO₂Et)₂ with EtONa or better with EtOK give Et 2-methylquinoxaline-3-pyruvate, orange-yellow, m. 129°, *p*-nitrophenylhydrazones, orange, m. 189°. 2-*ω*-Tribromomethylquinoxaline, pink, m. 109° (10% yield). 2,3-di-(*ω*-dibromomethyl)quinoxaline, m. 228°. 3-phenyl-2-*ω*-dibromomethylquinoxaline, m. 148° (90% yield). 3-Phenyl-2-phenylacetoxyethylquinoxaline, m. 126°, in 90% yield from 3-phenyl-2-benzylquinoxaline, AcONa and Br in AcOH, the *p*-chlorophenyl deriv., m. 119°. I and MeI at 90° for 6.5 hrs. give 80% of a methiodide, greenish yellow, m. 192°.

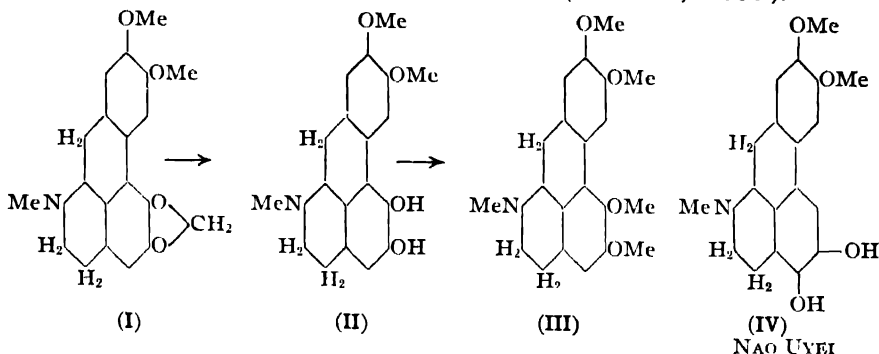

C. J. WEST

Decomposition of *o*-substituted aromatic acid azides. HANS LINDEMANN AND WERNER SCHULTHEIS. *Ann.* **464**, 237–53(1928).-*o*-HOCH₂C₆H₄CONHNH₂ with NaNO₂ (cooling) give *o*-hydroxymethylbenzoyl azide, m. 74.5° (decompn.) and then m. 119°; the azide is not very stable and gradually evolves N at room temp., heated in C₆H₆ or AcOH until gas evolution ceases, there results 2-keto-[4,5-benzo-1,3-oxazine] 1,2-dihydride, m. 119–20°; heated with 50% NaOH, this gives *o*-aminobenzyl alc., m. 83°. 2-Hydroxyphenylacetyl hydrazide, m. 152°; NaNO₂ and HCl give 2-hydroxyphenylacetyl azide, m. 51°, which is very unstable; with boiling C₆H₆ it yields 2-keto-[1,3-benzoxazine] 3,4-dihydride, m. 188°. With NaOH and BzCl there results 2-benzoyloxyphenylamine benzoate, m. 141.5°; 2 N NaOH gives the *N*-benzoate, m. 144°. Phthalyl diazide (I), m. 56° (decompn.); in another prepn. a very explosive compd. is obtained; either of these, warmed in C₆H₆ until N evolution ceases, gives 2-isocyanatobenzoate (II), m. 60° (decompn.); gradually heated over 100°, the mass solidifies and then m. 325°. In MeOH I or II gives 2-carbomethoxyaminobenzoyl azide (III), m. 80° (decompn.), then solidifies and m. 155°; the corresponding Et deriv. m. 64–6° (decompn.) and then m. 153°. Heating III in PhMe for 1 hr. gives *Me* benzimidazolone-*N*-carboxylate, m. 159°; the Et ester, m. 156°. II, heated with excess PhNH₂ in C₆H₆, gives *o*-carbonylazidodiphenylurea, m. 133°, detonates violently in a flame; heated in PhMe for 30 min., there results benzimidazolone-*N*-carboxanilide, m. 197°. I, boiled with PhMe for 45 min., gives dibenzimidazolonediuarea, m. 325°; aq. NaOH gives CO(NHPh)₂ and benzimidazolone.

Dicentrine and domesticine methyl ether. S. OSADA. Tokyo Imp. Univ. *J. Pharm. Soc. Japan*, **48**, 423–8(1928).—By boiling dicentrine (I) for 4 hrs. with 1,3,5-C₆H₃(OH)₃-H₂SO₄, the CH₂O₂ group is decompd. and the phenolic base (II) (red, sinters

140° and decomp. 175°, unstable to light) is obtained. The methylation of **II** with CH_3N_2 gave *d*-glauicine (**III**), bright yellow, m. 118°. The *l*-bitartrate, red, m. 202°, $[\alpha]_D^{20}$ 32°. In the same manner, domesticine mono-Me ether and 1,3,5- $\text{C}_6\text{H}_3(\text{OH})_3\text{H}_2\text{SO}_4$ gave the phenolic base (**IV**), m. 170–1° $[\alpha]_D^{20}$ 127.63°, which is more stable toward light than **II**. *l**l**l*Br salt, m. 253° (decompn.). The *l*-bitartrate, m. 196–7° (decompn.). **IV** and CH_3N_2 in MeOH gave the isoglauicine of Gorter (*l*-bitartrate, m. 204°).

NAO UYEE

Synthetic experiments on the aporphine alkaloids. III. Synthesis of corytuberine dimethyl ether. JOHN M. GULLAND AND ROBERT D. HAWORTH. Univ. of Durham. *J. Chem. Soc.* **1928**, 1834–8, cf. *C. A.* **22**, 2949.—2,3,4- $\text{O}_2\text{N}(\text{MeO})_2\text{C}_6\text{H}_3\text{CH}_2\text{COCl}$ and 3,4-(MeO)₂ $\text{C}_6\text{H}_3\text{CH}_2\text{CH}_2\text{NH}_2$ in C_6H_6 , shaken with 15% NaOH, give 2'-nitro-3',4'-dimethoxyphenylaceto- β -3,4-dimethoxyphenylethylamide, m. 64–5°, contg. solvent of crystn. lost at 100°; in CHCl_3 , PCl_5 at room temp for 36 hrs. it gives 2'-nitro-6,7,3',4'-tetramethoxy-1-benzyl-3,4-dihydroisoquinoline, pale yellow, m. 159–60°; *HCl* salt, very pale yellow, m. 227° (decompn.), *methiodide*, yellow needles with solvent of crystn., m. 105–7° and then gradually decomp. between 180–90°. Reduction of the *methiodide* with Zn and HCl gives 2'-amino-6,7,3',4'-tetramethoxy-1-benzyl-2-methyl-tetrahydroisoquinoline, analyzed as the *di-HCl* salt, m. 188–90°, with HNO_2 this gives a bright yellow soln., giving a vermilion azo dye with alk. β - $\text{C}_{10}\text{H}_7\text{OH}$. Warming the diazo soln. in $\text{MeOH-H}_2\text{SO}_4$ gives *dl*-corytuberine *di-Me ether* (**I**), pale yellow oil, whose *methiodide* decomp. 248°. **I** and *d*-tartaric acid in EtOH give *l*-**I** *d*-bitartrate, m. 219–21° (decompn.), $[\alpha]_D^{20}$ -148.2° (H_2O , *c* 1.005); the *d*-**I** *l*-bitartrate is identical with that of Gadauner from the natural product; other reactions and the *methochloride* appear to confirm the identity and thus establish the structure suggested by G.

Lupine alkaloids. I. GEORGE R. CLEMO AND GRACE CUMMING LEITCH. Univ. of Durham. *J. Chem. Soc.* **1928**, 1811–20.—The facts previously established regarding lupanine (**I**) are that it possesses a very stable, fully satd. ring system with 1 reactive tert. N atom, and no reactive CO, HO or MeO group. The basic nature of both N atoms is now shown by the formation of *I*-*di-HCl*, m. 185° (decompn.), which is deliquescent, its aq. soln. being acid to litmus; heated under 1-mm. pressure, a sublimate of the very deliquescent cryst. *mono-HCl* salt is formed. However, **I** yields only a *monomethiodide* (**II**), m. 262–3° (decompn.) and a *monomethosulfate*, m. 196°. The *methiodide* is unchanged after refluxing with MeOH-KOH ; distn. of the hydroxide gives **I** and MeOH; heated with NaOH and KOH at 1-mm. pressure, there results a mixt. of α -methyllyupanine, m. 123° (*mono-HCl* salt, m. 209° (decompn.) *methiodide*, m. 258° (decompn.)), and β -methyllyupanine, isolated as the *methiodide*, m. 272° (decompn.). **II**, heated with KOH at 260°, gives a base $\text{C}_{17}\text{H}_{22}\text{N}_2$, b₁ 130°; *picrate*, yellow, m. 137°; *dimethiodide*, m. 202°, decomp. 280°. Heating **I** with HI and red P 36 hrs. at 220° gives *deoxylupanine* (**III**), b₁ 145°; the aq. soln. has an alk. reaction; the *di-HCl* salt is deliquescent; *monopicrate*, yellow, m. 135°; *dipicrate*, lemon-yellow, m. 206–7°; *methiodide*, m. 226°. Oxidation of **III** gives *isolupanine*, m. 113°; *methiodide*, m. 208°. Oxidation of **I** with KMnO_4 gives *oxylupanine*, $\text{C}_{15}\text{H}_{22}\text{O}_2\text{N}_2$, m. 123°; *chloroplatinate*, brown, m. 232° (decompn.); it does not react with PhNHNH_2 , with BzCl , with piperonal or with AcOH satd. with HCl.

C. J. WEST

Etholides of coniferous waxes. J. BOUGAULT AND E. CATTELAINE. *Compt. rend.* **186**, 1746–8 (1928); cf. *C. A.* **3**, 783, 2445; **4**, 2094; **5**, 2441; Ruzicka, *C. A.* **21**, 2888; Kerschbaum, *C. A.* **21**, 2118.—From the studies referred to above it appears that juni-

peric acid is important as a basis for the prepn. of compds. with the odor of musk. A natural source of this acid was sought in *Abies nordmanniana* Spach., *Pinus austriaca* Link. and *P. maritima* Lamk., the leaves of which contain 1.0, 1.8 and 1.7 g. per kg., resp., of juniperic acid, and 0.0, 0.3 and 1.2 g. per kg., resp., of sabinic acid. L. W. R.

Acid constituents of sandarac resin. ALEXANDER ROLLETT, PETER TABAKOFF AND STEFAN FEIMER. Univ. Graz. *Monatsh.* 50, 1-5(1928).—The resin, purified as described in the literature, is sepd. into 2 parts by KOH; the K salt of sandaracolic acid ppts. as a heavy, sticky mass; HCl ppts. the free acid, which is purified through the Pb salt, when it m. 192°; Br in AcOH gives an amorphous product, m. 226°, probably not homogeneous; heating the acid with 8-10% H_2SO_4 on the H_2O bath gives a product, m. 212°. Dialysis of the acid in 0.5 *N* KOH gives callitricolic acid, $C_{20}H_{30}O_8$, m. 263°. Shaking an Et_2O soln. with 0.1% $(NH_4)_2CO_3$ gives sandaracinic acid, which is amorphous; the Me ether, amorphous, m. 159°. Further extn. with 0.1% Na_2CO_3 gives sandaracinolic acid, m. 199°; heating with Ac_2O raises the m. p. to 223° (rearrangement?); finally there is obtained sandaracopimaric acid, m. 248°. C. J. WEST

Toad poison. I. Composition of the Chinese remedy "senso." MUNIO KOTAKE. Inst. for Phys. and Chem. Research, Tokyo. *Ann.* 465, 1-11(1928).—Extn. of "senso" with 95% EtOH gives bufagin (I), to which is assigned the formula $C_{29}H_{38}O_7$ (Kodama gives $C_{27}H_{34}O_2$); *di-Ac deriv.*, m. 196-7°. Catalytic reduction of I gives a mixt. of the α -tetrahydro deriv., crystg. with $2H_2O$, m. 130-40°, and then 230-2°, and the β -deriv., m. 208-10°; reduction of the di-Ac deriv. gives a mixt. of 2 tetrahydro derivs., m. 238° and 254-7°. Acetylation of the α -tetrahydro deriv. gives the compd. m. 238°, while the β -deriv. gives a mixt. of the 2 isomers. Oxidation of I with CrO_3 gives bufagone, $C_{29}H_{36}O_7$, m. 232-5° (oxime, m. 170-3°). Bufalin chloride, m. 218-20°, with $AcONa$ and Ac_2O gives acetylanhydrobufalin, m. 221-5°. Oxidation of the chloride gives bufalinone chloride, m. 251-2°; Ac_2O and $AcONa$ give anhydrobufalinone, m. 181-3°. The action of KOH (1:1) on I gives AcOH, analyzed as the Ag salt. These results indicate that I contains a lactone group, an Ac group, a sec. HO group, a tert. HO group and 2 double bonds. Only 1 O atom remains unexplained. **II. The poisonous constituent of the secretion of the Japanese toad (*Bufo japonicus*).** *Ibid* 11-20.—Extn. of the skins of 5000 toads (*Bufo bufo japonicus*) with EtOH gives 35 g. gamabufotalin (II), $C_{27}H_{38}O_6$, m. 261-3° (decompn.). H_2SO_4 added to a $CHCl_3$ soln. is colored yellow; a few drops of concd. H_2SO_4 added to an Ac_2O soln. colors the soln. indigo-blue, quickly changing to green. No oxidation product could be obtained cryst. *Di-Ac deriv.*, m. 225°; 0.6 g. absorbs 100 cc. II, but a cryst. product could not be isolated. With alc. KOH I gives gamabufotilinic acid, $C_{24}H_{36}O_6$, decomps. 207-9°. Catalytic reduction of I gives a hydro deriv., $C_{24}H_{38}O_5$, crystg. with 1 EtOH, m. 131-3°. Concd. HCl and I give hydrogamabufotalin, m. 263° (decompn.). HCO_2H gives a diformyl ester, m. 156-7°; at the summer temp., a compd., $C_{27}H_{38}O_{13}$, m. 212-4°, is obtained. The formyl ester with HCl gives the anhydro deriv. With HCl I gives gamabufalin chloride, m. 217-9°, which with Ac_2O and $AcONa$ yields acetylanhydrogamabufalin, m. 227-9°. Acetylgamabufalin, m. 256-8°. C. J. WEST

Photochemical oxidation of ergosterol. A. WINDAUS AND J. BRUNKEN. Univ. Göttingen. *Ann.* 460, 225-35(1928); cf. C. A. 22, 2169.—Ergosterol undergoes photooxidation in 95% EtOH in the presence of eosin when submitted to radiation from a powerful filament lamp. Eosin may be replaced by other fluorescent substances, such as erythrosin, methylene blue, chlorophyll or hematoporphyrin. Acridone is feebly sensitizing but rosaniline has no effect. KCN does not inhibit the reaction but no action occurs in the dark. The reaction product is ergosterol peroxide, $C_{27}H_{42}O_8$, m. 178°; it shows a normal mol. wt. in $C_{10}H_8$ or camphor; $[\alpha]_D^{18} = -35.5^\circ$ (0.2805 g. made up to 10 cc. in $CHCl_3$). The peroxide is very unstable in the presence of acids. As $AsCl_3$ in $CHCl_3$ gives a greenish blue, then deep blue and finally a violet color; $SbCl_3$ gives a brown-violet, $SnCl_4$ a wipe-red color. Concd. H_2SO_4 , shaken with the peroxide in $CHCl_3$, becomes deep red. Distd. in a high vacuum, the peroxide gives a cryst. distillate, but it is for the most part unchanged up to 180-5°. Digitonin gives an addn compd., $[\alpha]_D^{16} = -39^\circ$ (0.1221 g. in 10 cc. C_6H_5N). Ac_2O gives the acetate, m. 202°, also obtained by the photooxidation of ergosteryl acetate in EtOH-eosin, followed by sapon. with 5% EtOH-KOH. Reduction of the peroxide with Na and EtOH gives ergosterol and then dihydroergosterol, m. 173-4°, $[\alpha]_D^{17} = -20.4^\circ$ ($CHCl_3$); acetate, m. 180-1°, $[\alpha]_D^{16} = -20^\circ$ ($CHCl_3$); these products are also directly obtainable from ergosterol. Traces of the latter may be removed from the dihydro deriv. by treatment with blood charcoal in EtOH or by photooxidation. The dihydro deriv. gives no color reactions with $AsCl_3$ or $SbCl_3$ but H_2SO_4 gives a yellow, then orange, soln. Reduction of its

acetate gives γ -ergostyl acetate. Ergosterol peroxide, whether irradiated or otherwise, has neither antixerophthalmic nor antirachitic action, while ergosterol prep'd. from the peroxide is still capable of activation. This suggests that it is ergosterol itself and not an impurity present in it which forms the antirachitic provitamin. Dihydroergosterol, before or after irradiation, is physiol. inactive.

C. J. WEST

Photochemical dehydrogenation of ergosterol. A. WINDAUS AND P. BORGEAUD. Univ. Göttingen. *Ann.* 460, 235–9 (1928).—Ergosterol in EtOH contg. eosin or erythrosin (chlorophyll has a feeble sensitizing action, while methylene blue and rosaniline have none) undergoes photo-dehydrogenation in a glass vessel in sunlight to give *ergopinacol*, $C_{28}H_{42}O_2$, m. 202–3° (decompn.), $[\alpha]_D^{16} -209^\circ$ (C_6H_5N). Conc'd. H_2SO_4 becomes orange when shaken with the pinacol in $CHCl_3$. On distn. at 0.1 mm. (bath at 210°) the latter affords *neobergosterol*, $C_{27}H_{42}O$, m. 151–2°, $[\alpha]_D -12^\circ$ (*acetate*, m. 122–3°), also formed by reducing ergopinacol with Zn and AcOH. Neither of the 2 new products possesses antirachitic action, whether previously irradiated or not.

C. J. WEST

The hydrofluorides of organic bases (BERLINER, HANN) 6. Constitution of hydrazoic acid and its esters (LINDEMANN, THIELE) 6. The electrochemical oxidation of hydrocinnamic acid (FICHTER, SENTI) 4. LAWRIE, JAMES W.: Glycerol and the Glycols—Production, Properties and Analyses. New York: The Chemical Catalog Co., Inc. Am. Chem. Soc. Monograph No. 44. 457 pp. \$9.50. Reviewed in *Ind. Eng. Chem.* 20, 986 (1928).

Unsaturated hydrocarbons and hydrogen. I. G. FARBENIND. A.-G. Fr. 634,210, Mar. 28, 1927. See Brit. 269,547 (*C. A.* 22, 1364).

Catalytic production of unsaturated hydrocarbons. SOC. D'ETUDES ET D'EXPLOITATION DES MATIERES ORGANIQUES. Brit. 282,690, Dec. 21, 1926. C_2H_2 and other hydrocarbons of the same series are obtained from gaseous mixts. such as H, CH_4 and CO by incomplete combustion with O in the presence of a catalyst such as Pt black or sponge, oxides of Fe, Cu, Ni, Cr, V, Ag, Pd or Ce. An app. is described.

Partial oxidation products of aliphatic hydrocarbons. JOSEPH H. JAMES (to Clarence P. Byrnes, trustee). U. S. 1,681,185, Aug. 21. Products such as those obtained by catalytic partial oxidation of hydrocarbon vapors, which comprise a mixt. including aldehyde-like compds. and oxygenated org. acids, are treated to sep. the acids from the other constituents and convert them into salts, *e. g.*, by use of $Ca(OH)_2$.

Purifying partial oxidation products obtained from hydrocarbons. JOSEPH H. JAMES (to Clarence P. Byrnes, trustee). U. S. 1,681,228, Aug. 21. The mixt. obtained by catalytic partial oxidation of hydrocarbons or other similar mixt. contg. normally liquid hydrocarbons together with various products of partial oxidation ranging in degree of oxidation from alcs. through aliphatic aldehyde-like compds. to oxygenated org. acids, is purified by chem. addn. to unsatd. bonds of compds. present, *e. g.*, by hydrogenation or halogenation.

Products of heating of alcohol with catalysts. CONSORTIUM FÜR ELEKTRO-CHEMISCHE INDUSTRIE GES. Brit. 282,448, Dec. 18, 1926. EtOH is circulated at ordinary pressure and a temp. of 400–500° over BaO; the products comprise higher alcs. such as BuOH, acids, esters such as EtOAc, acetals such as diethylacetal and aldehyde. MgO lime, Mn oxide, Mg alcoholate and Na alcoholate also may be used as catalysts to effect similar reactions.

Polymerizing constituents of naphtha. STUART P. MILLER and JOSEPH B. HILL (to The Barrett Co.). U. S. 1,679,093, July 31. Naphtha contg. polymerizable constituents is emulsified with H_2SO_4 , $AlCl_3$, or other polymerizing agent in a continuous process. An app. is described.

Highly chlorinated perylenes. ALOIS ZINKE and KONRAD FUNKE (to Felice Bensa). U. S. 1,681,077, Aug. 14. Products such as hepta- to dodecachloroperylenes are formed by mixing an inert liquid solvent such as $PhNO_2$ with perylene and $AlCl_3$, $SbCl_5$ or other suitable inorg. chloride adapted to act as a Cl-transferring agent, and passing a current of dry gaseous Cl through the mixt.

Alkylcoumarans. HANS JORDAN (to Chem. Fabrik auf Aktien vorm. E. Schering). U. S. 1,679,664, Aug. 7. See Can. 278,727 (C. A. 22, 2754).

Amino compounds. FABRIQUES DE PRODUITS DE CHIMIE ORGANIQUE DE LAIRE. Brit. 282,083, Dec. 9, 1926. Production of primary amines by treatment of compds. such as oximes and nitriles with H in the presence of a hydrogenating catalyst is effected in the presence of NH_3 which may be added as such or in the form of a salt or complex ammoniacal compd. Examples are given of the production of (a) ethylamine from a mixt. of NH_3 , H and acetonitrile vapor in the presence of reduced Ni at 180° ; (b) benzylamine from NH_3 , H and benzonitrile vapor with reduced Cu at 250° ; (c) 2-aminopropane from propanone oxime, NH_3 , H and Ni; (d) ethylamine from a soln. of acetonitrile with NH_3 in aq. alc. satd. with NH_4Cl agitated with H in the presence of Ni under pressure at 50° ; (e) β -phenylethylamine from a mixt. of benzyl cyanide and an alc. soln. of NH_3 with H and reduced Ni, with or without use of heat and pressure; (f) benzylamine from benzonitrile and finely divided Ni agitated in an atm. of NH_3 and H under pressure at 100° .

Reduction of aromatic amines. I. G. FARBENIND. A.-G. Fr. 634,031, May 7, 1927. Substituted aromatic amino compds. are reduced by H under pressure in the presence of catalysts contg. metals such as Ni, Co or Cu. Examples are given of the prepn. of hexahydroethylamine, acetyl- α -tetrahydro- α -(or β)-naphthylamine, 2-amino-3- α -tetrahydronaphthoic acid.

Halogenated tertiary amines and ammonium compounds. I. G. FARBENIND. A.-G. Fr. 634,255, May 2, 1927. Halogenated tertiary aromatic amines are prepd. by treating with halogens the aq. solns. of the mineral acid salts of tertiary aromatic amines, the soln. may contain free acid. Ammonium compds. of the above are prepd. by treating them with alkyl esters of H_2SO_4 or of arylsulfonic acids with or without a solvent. Several examples are given.

Soluble products from fatty acids. RAYMOND VIDAL. Fr. 633,922, April 19, 1927. Fatty acids such as stearic, oleic or ricinoleic acid are treated with alkali hypochlorites or hypobromites and then with an acid such as H_2SO_4 . The products obtained, either alone or with org. compds. halogenated or not, give, with a smaller quantity of hypochlorite or bromite, a thick paste, which has various industrial applications, in tanning, lubricating, washing, etc.

Aliphatic dicarboxylic acids. J. D. RIEDEL A.-G. Fr. 634,196, Feb. 5, 1927. Aliphatic dicarboxylic acids are prepd. by oxidizing hydroaromatic alcs. and ketones in the presence of O transferors.

Organic arsenic compounds. I. G. FARBENIND. A.-G. Brit. 281,690, Dec. 2, 1926. N-substituted arsenobenzimidazolones are made by reducing the N-substituted benzimidazolonearsinic acids the prepn. of which is described in Brit. 256,243 (C. A. 21, 2908). Examples are given of the production of benzethyl, benzpropyl and benzallylimidazolones by reducing the corresponding arsonic acids with hyposulfite.

Organic arsenic compounds. I. G. FARBENIND. A.-G. Brit. 281,703, Dec. 2, 1926. 3,4-Benz-(3-N-methyl)-imidazolonecarsonic acid is made by diazotizing 1-amino-3,4-benz-(3-N-methyl)-imidazolone, adding arsenious acid and excess of NaOH, and isolating the product with HCl. 3,4-Benz-(4-N-ethyl or propyl)-imidazolonecarsonic acids are similarly prepd. from the corresponding amino compds. Examples are also given for producing the 1-amino-3,4-benz-(4-N-ethyl or propyl)-imidazolones.

Arseno compounds. ARTHUR BINZ and CURT RATH. U. S. 1,678,760, July 31. In producing various compds. contg. the —As:As— group, an org. arsonic acid such as 2-hydroxy-5-pyridylarsonic acid is reduced by the action of Na hypophosphite or other suitable reducing agent in the presence of 4-hydroxy-3-aminophenylarsine or like compd. contg. the group —AsH₂. Cf. C. A. 21, 1660.

Esters. GEORGE BARSKY (to American Cyanamid Co.). U. S. 1,678,719, July 31. In making esters such as ethyl hydroxybutyrate, an org. acid, e. g., butyric acid, is heated with the nitrile corresponding to the acid, and with an alc. such as EtOH in the presence of HCl or other suitable inorg. acid.

Esters of cholesterol with unsaturated organic acids. WALTER MINNICH (to Soc. anon. pour l'ind. chim. à Bâle). U. S. 1,680,799, Aug. 14. By reaction of cholesterol with crotonic acid chloride in a reflux app. at 160° an ester is obtained which may be recrystd. from alc. It softens at 90° and melts to a clear liquid at 149° . Mention is also made of the production of similar esters, having therapeutic properties, from various acids of the general formula R.COOH (in which R stands for a low aliphatic hydrocarbon radical carrying at least one double bond). In forming the esters, cholesterol itself or its halides may be caused to react either with the free acid or its halide or anhydride.

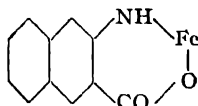

Ketones. SCHERING-KAHLBAUM A.-G. Brit. 282,412, Dec. 15, 1926. Alkyl

β -halomethyl ketones are prep'd. by reacting on C_2H_4 with an acyl halide in the presence of a catalyst or condensing agent such as Al or Fe halide, and treating the product with water, preferably without heating. Solvents or diluents such as $CHCl_3$, CS_2 , $PhNO_2$, C_6H_{14} or an excess of the acyl halide itself may be present. Methyl β -bromomethyl ketone and methyl β -chloroethyl ketone are made from C_2H_4 and acetyl bromide or chloride.

Oxalates. ISADORE S. MELLANOFF (to Kemikal, Inc.). U. S. 1,681,156, Aug. 14. Materials such as waste newspapers are pulped and heated with alkali such as NaOH, preferably while passing air through the mass, at a temp., of about 200° ; a small proportion of a heavy hydrocarbon oil or paraffin is then added and the heating is further continued at a slightly higher temp. (suitably about 210°) and the temp. of the reaction mass then very gradually reduced. Rags, straw and other waste materials also may be used. Na oxalate is formed together with some other salts of different aliphatic acids. The oil or paraffin promotes the reaction.

Anthraquinone derivatives. I. G. FARBENIND. A.-G. Brit. 282,004, Dec. 9, 1926. 1-(2'-Carboxyphenyl)anthraquinones are made by oxidation of Bz-1-Bz-2-benz-benzanthrones or their derivs. The benzbenzanthrone used as starting materials are obtained by ring closure of benzylideneanthrones with $AlCl_3$.

Naphthalene derivatives. I. G. FARBENIND. A.-G. Brit. 282,450, Dec. 17, 1926. 2-Aminonaphthalene-3-carboxylic acid is obtained by heating 2-hydroxynaphthalene-3-carboxylic acid or an alkali salt under pressure with NH_3 and a ferrous salt and decomp. the resulting complex Fe comp'd. by prolonged heating with strong acid or alkali. The Fe comp'd. formed as an intermediate probably has the formula

Alkylpyrazoleanthrones. I. G. FARBENIND. A.-G. Brit. 282,375, Dec. 14, 1926. Pyrazoleanthrones are treated with alkylating agents such as $EtBr$, Me_2SO , or Et_2SO_4 in the absence of condensing agents and preferably in the presence of acid-binding agents. With Et_2SO_4 , a mixt. of 2 ethylation products is obtained which may be sep'd. by extn. with C_6H_6 .

Removing metal carbonyl from organic liquids. CARL MÜLLER, WALTER FRANKENBURGER and FRIEDRICH GRASSNER (to I. G. Farbenind. A.-G.). U. S. 1,679,256, July 31. Synthetic MeOH or other liquids contg. less than 10% of metal carbonyl such as Fe carbonyl are exposed to the action of ultra-violet rays which also act on aldehydes or ketones present. Ozone also may be used.

Acetic and formic acids. W. N. HAWORTH and J. NELSON, LTD. Brit. 281,827, Oct. 19, 1926. Aq. acetic or formic acid is conc'd. by adding an acetate or formate such as the Na salt and then distg. off the strong acid; at least part of the distn. is effected under reduced pressure. A rotary still with scrapers or a fixed still with agitating or grinding devices may be used.

Acetic acid and acetates. PHILIP A. SMITH and HAROLD G. SMITH (to Synthetic Ammonia & Nitrates, Ltd.). U. S. 1,679,994, Aug. 7. See Can. 273,715 (*C. A.* 21, 3906).

Concentrating acetic acid. I. G. FARBENIND. A.-G. Fr. 633,817, May 3, 1927. AcOH is conc'd. by extn. with org. bases not attacked by conc'd. AcOH, such as quinoline, quinaldine, $PhNMe_2$ or $PhNEt_3$. Substances insol. in water such as benzene, $CHCl_3$, CCl_4 , may also be added to reduce the amt. of water extd. along with the AcOH. An app. is described.

Acetic anhydride. CONSORTIUM FÜR ELEKTROCHEM. IND. G.M.B.H. Fr. 634,466, May 16, 1927. Vapor of AcOH is heated in the presence of a catalyst to temps. between 400° and 800° , the surfaces transmitting the heat of the heating chamber being composed of metalloids or metals resistant to heat, e. g., Si, SiC, C, Cu or Cu alloys. Cf. *C. A.* 22, 1783, 2755.

Acetic anhydride. HENRY DREYFUS. Fr. 633,856. May 4, 1927. See Brit. 279,916 (*C. A.* 22, 2951).

4'-Amino-2-benzoylbenzoic acid. NEWPORT Co. Brit. 282,001, Dec. 8, 1926. The Na salt of 4'-chloro- (or other halogen) 2-benzoylbenzoic acid is heated under pressure with aq. NH_3 (suitably in the presence of a catalyst such as Cu or $CuSO_4$).

Ethylidene diacetate. MAURICE E. BOUVIER and LUCIEN HUGONOT (to Soc. chimique des usines du Rhone). U. S. 1,680,760, Aug. 14. Absorption of C_2H_4 in

HOAc in the presence of a Hg salt is effected at a temp. below the b. p. of the liquid in the presence of a strong acid such as sulfoacetic acid and of Ac_2O in such quantity that when the reaction is completed some Ac_2O still remains in the liquid.

Butyraldehyde. CONSORTIUM FÜR ELEKTROCHEM. IND. G.M.B.H. Fr. 634,320, May 13, 1927. See Brit. 271,103 (C. A. 22, 1596).

Crotonaldehyde. ELEKTROCHEMISCHES WERK LONZA. Fr. 634,259, May 4, 1927. For the prepn. of crotonaldehyde AcH is mixed in an atm. of N with only so much dil. caustic alkali soln. that on neutralization with a mineral acid no pptn. takes place, and the reaction mixt. is fractionally distd. directly in an atm. of N.

Formaldehyde from methylene chloride. ERICH KRAUSE and KOLOMAN ROKA (to Holzverkohlungs-Industrie A.-G.). U. S. 1,679,673, Aug. 7. Methylene chloride is heated in the presence of water in a closed vessel to 120–170° and acid-binding materials such as NH_3 , Na_2CO_3 , or alkali metal hydroxides capable of reacting with CH_2O are added gradually in such quantities that alk. reaction of the mixt. is avoided. Cf. C. A. 21, 918.

Naphthalene. GEORG SCHROETER. U. S. 1,680,070, Aug. 7. In order to remove from C_{10}H_8 impurities which would act as catalyst poisons in the presence of a hydrogenation catalyst, the material, at a temp. above its m. p., is subjected to the action of Na amide or other suitable material comprising a metal loosely combined with a non-acid agent.

Nitroguanidine. ARTHUR P. TANBERG and RICHARD L. KRAMER (to E. I. Du Pont de Nemours & Co.). U. S. 1,679,752, Aug. 7. In order to obtain it in finely divided form, nitroguanidine is dissolved in water under superatm. pressure at a temp. above 100° to form a more concd. soln. than could be obtained at 100° and this soln. is then discharged into a cold liquid medium such as cold water to effect pptn. of the nitroguanidine.

Fructose. CHEM. FABRIK AUF AKTIEN. FORM. E. SCHERING. Fr. 634,363, May 13, 1927. See Brit. 272,876 (C. A. 22, 1871).

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

Melibiose. II. R. WEIDENHAGEN. Z. Ver. deut. Zucker-Ind. 1928, 99–110; cf. C. A. 22, 608.—Purified yeast melibiase has a max. activity at p_{H} 4.8, but it does not vary much between p_{H} 3.5 and 5.5. With varying concns. of enzyme the same percentage of melibiose is hydrolyzed in times inversely proportional to the concn. of the enzyme provided the other conditions are kept const. The activity of melibiase in certain preps. is within limits approx. represented by the formula for a unimol. reaction. Suitable units in which to measure the activity of melibiase and the concn. of it in any particular material are suggested, following the principles used by Willstätter (C. A. 15, 1730) in relation to maltase. Methods are described for the prepn. of melibiase solns. and for the detn. of melibiase in yeast. B. C. A.

Investigations on the imitation of organic forms with albumin. II. L. A. HERRERA. Lab. Altí Studii Biol. Messico. Atti accad. Lincei [6], 7, 544–7 (1928).—In continuation of the earlier expts. (cf. C. A. 22, 1983) HCl was used in place of H_2SO_4 , the same technic being used again. The acid must be very dil. and more water must be added as soon as the org. forms are developed. HCl gives finer and more complex forms than does H_2SO_4 . Large vacuoles, pseudopods, protoplasm-like granules and hairs similar to those of infusoria are visible, and many of the forms resemble in a striking manner such living objects as the *Allogromia*, *Actinosphaerium eichornii* and *Paramoecium caudatum*. The hairs and pseudopods probably result from the rapid diffusion of albumin in the water, followed by an equally rapid gelation. Like living organisms, these forms are composed of partially hydrolyzed albumin, water, salts, traces of SiO_2 , etc. Plant and animal albumins always contain traces of SiO_2 , and it is possible that SiO_2 is the basis of life and the substratum of the first organisms. SiO_2 has a high adsorptive capacity, and the silicic micelles may have adsorbed products of photosynthesis and thus may have induced the appearance of life. C. C. DAVIS

Cozymase and its determination. KARL MYRBÄCK. Univ. Stockholm. Z. physiol. Chem. 177, 158–69 (1928); cf. C. A. 21, 1820.—Contrary to the views recently expressed by Kostychev and by Struyk the existence of cozymase as a necessary factor

in the fermentation of sugar is upheld. The factors required for the breakdown of sugar by yeast are (1) the enzyme system, (2) inorg. phosphates, (3) hexosediphosphate, (4) cozymase, (5) maintenance of proper acidity. The theory of cell-free fermentation is defended. Arguments against Kostychev's assertion of the non-existence of such fermentation are the fact that living yeast and dried yeast show different p_H optima and different degrees of sensitivity toward toluene. Where failures to obtain fermentation have been reported and attributed to the absence of living cells, it is probable that one or more of the above essential factors was lacking.

A. W. DOX

Experiments on carbohydrate metabolism in dried muscle. HANS V. EÜLER, EDVARD BRUNIUS AND STIG PROFFE. Univ. Stockholm. *Z. physiol. Chem.* 177, 170-6(1928).—The previously reported observation that purified cozymase gives a much feeblar activation of lactic acid formation from glycogen or glucose by dried muscle preps. than does boiled yeast ext. was not corroborated with new preps. of muscle. This difference is attributed to variations in the amt of inhibitory substances rather than to some unknown factor in the yeast ext. which contributes to the activation.

A. W. DOX

The nature of the proteases. I. The ratio of amino to carboxyl groups in various pepsin preparations. I. A. SMORODINTZEV AND A. N. ADOVA. Univ. Moscow. *Z. physiol. Chem.* 177, 187-200(1928).—The activity of various commercial pepsin preps. is directly proportional to their total N, amino N and COOH content. In the more active preps. the peptide-COOH is in excess of the amino acid-COOH, the ratio varying between 2.64 and 3.41; in the weak preps. it varies between 0.8 and 1.5. The NH_2 to COOH ratio is about 0.75 in the active preps., and below 0.5 in the weak preps. The electrotitration curve of solns. of weak pepsins shows a steeper rise than that of the stronger pepsins. When kept for some time with an equal amt. of glycerol the natural gastric juice of the dog undergoes a simultaneous diminution of activity and an increase in amino-N content, and the ratio of NH_2 to COOH rises to 6.82. Natural gastric juice which has lost its activity shows an increase in amino acid-COOH, and a drop in polypeptide-COOH almost to zero.

A. W. DOX

Enzymic experiments with dried muscle. EDVARD BRUNIUS. Univ. Stockholm. *Z. physiol. Chem.* 177, 201-4(1928).—After addn. of Meyerhof's activator (designated as MX) the lactic acid formation by dried muscle shows a distinct optimum with 0.06-0.08 M phosphate buffer, corresponding to 1-1.3% phosphate. Under ordinary conditions the phosphate optimum is 3%. The presence of PhMe has no apparent effect on lactic acid formation. When extd. with H_2O , and glucose, MX and cozymase added to the residue, the ability of the dried muscle to form lactic acid is considerably diminished, although the filtrate shows no activity. Treatment of dried muscle with 40% EtOH contg. sufficient HCl to give a faint red with methyl orange results in loss of activity which cannot be restored by addn. of the ext.

A. W. DOX

Buffer studies. X. The buffering of the feces. M. KARTAGENER. Univ. Basel. *Helv. chim. Acta* 11, 548-62(1928).—The purpose was to det. the influence of the solid phase of feces on the H-ion concn. of the liquid or soln. phase. Different dilns. of an AcOH-acetate buffer mixt. of known p_H strength were shaken $1\frac{1}{4}$ hrs. with insol. secondary and tertiary Ca phosphates, (as typical feces salts), and the p_H was detd. again. Conclusions: The H-ion concn. of a definite buffer soln. that is in equil. with a solid body is markedly influenced by the solid. The degree and direction of the change that the original p_H undergoes depend first on the state and concn. of the soln. and second on the chem. nature of the solid phase, which itself acts as a buffer tending to regulate the H-ion concn. of the soln. phase. The capacities of the buffers are unappreciably altered as long as the solid phase is present. By using lactic acid-lactate buffers instead of the acetate it was found that the nature of the acid ions also played a role in the change in p_H .

RUSSELL C. ERB

Oxidation of luciferin without luciferase and the mechanism of bioluminescence. E. NEWTON HARVEY. Princeton Univ. *J. Biol. Chem.* 78, 369-75(1928).—Luminescence in the absence of luciferase (I) did not occur on oxidizing luciferin (II) at anodes of various metals (Mn, Al, Ag, Ni, Sn, Cu, Fe, Pb, Zn, Cd, Pt) by nascent O; or oxidation by colloidal Pt or Pd and O or oxidizing agents. A soln. of I connected electrically with a soln. of II by Pt electrodes in metallic contact and a salt bridge gave no luminescence. Neither I nor II mixed with oxidized siloxene hydroxide and oxidized with acid permanganate luminesces. Fluorescent dyes do not luminesce in the presence of oxidizing I or II alone. II in alc. luminesces slightly on heating or on the addn. of $KMnO_4$, ozonized turpentine, disuccinyl peroxide and some other oxidizing agents, these being the only known conditions in which II luminesces without I. From these facts it is concluded that II is not the source but merely an accessory of bioluminescence.

and that I is the active cause of light. A probable hypothesis is that luminescence results through excitation of I by the energy of oxidation of II, and that I increases this rate of oxidation.

RUSSELL C. ERB

Chemical constitution of the respiration enzyme. OTTO WARBURG. *Naturwissenschaften* 16, 245-50(1928).—The equilibria hemoglobin- $\text{CO}\cdot\text{O}_2$ and respiration enzyme- $\text{CO}\cdot\text{O}_2$, including the action of light on them, are discussed. Hemoglobin differs from the respiration enzyme in that it has no catalytic action and it binds CO more firmly than the enzyme. Free hemin approaches more nearly the enzyme qualities. Even more similar to the enzyme are compds. of hemin with pyridine or nicotine. Cytochrome is shown to be different from respiration enzyme. Spectroscopic analysis of the compd. of hemin with nicotine shows the identity of its light-absorption curve and the curve of its catalytic activity *versus* λ . This method applied to live yeast yielded the absorption curve for respiration enzyme. It is a typical hemin spectrum with its max. absorption at 436μ instead of 408μ . Surface absorption on solid cell constituents of the hemin may possibly cause this shift.

B. J. C. VAN DER HOEVEN

Artificially increased permeability of skin to the short-wave rays and fluorescence of skin irradiated with ultra-violet rays. W. E. PAULI. *Strahlentherapie* 26, 577-85 (1927); *Ber. ges. Physiol. exptl. Pharmacol.* 44, 606; cf. C. A. 22, 2759.—Glycerol contg. a little alc. was found to be the best agent for increasing the permeability of the skin to ultra-violet rays. The permeability increases with the length of irradiation. Normal skin has a pronounced fluorescence; rabbit's skin 540-420, max. 500μ , human skin max. 460μ . The exciting rays are 300μ . The fluorescence curve is to a large extent coincident with the erythema curve. The fluorescence of the skin is to be taken into account when the intensity of irradiation is measured.

MARY JACOBSEN

Differences in physicochemical properties of various proteins in plant seeds. III. Soy-bean proteins. TETSUTARO TADOKORO AND KATSUJI YOSHIMURA. *J. Coll. Agr. Hokkaido Imp. Univ.* 20, 355-62(1928); cf. C. A. 22, 967.—The ppt. obtained from dialyzing the H_2O ext. of soy beans was designated glycinin A. From the filtrate legumelin was pptd. with $(\text{NH}_4)_2\text{SO}_4$. From the residue of the H_2O extn. of soy beans glycinin B was extd. with 10% NaCl and from this residue glutelin was extd. by 0.2% NaOH. The order of decreasing ash and P and increasing N content is legumelin, glycinin and glutelin. The isoelec. point of glycinin is at the highest p_{H} and of legumelin the lowest. The order of increasing free amino N is glycinin, glutelin and legumelin. Glycinin, the main protein of soy beans, has the isoelec. point of the highest p_{H} value, the highest sp. rotation, nitrogen content and free amino N. H. R. K.

The enzymic oxidation of oxalic acid by plant seeds. A contribution to the knowledge of the constitution of oxalic acid. TORSTEN THUNBERG. *Skand. Arch. Physiol.* 54, 6-16(1928).—Powdered seeds of *Nalva crista* or exts. of the same as well as other seeds show an increased capacity to reduce methylene blue *in vacuo* after the addn. of $\text{K}_2\text{C}_2\text{O}_4$. The oxalate seems to participate as a H donor, which presupposes the hydration of the mol. The reaction is thought to proceed thus: $\text{K}_2\text{C}_2\text{O}_4 + 2\text{H}_2\text{O} \longrightarrow [\text{C}(\text{OH})_2\text{OK}]_2 \xrightarrow{-2\text{H}^+} 2\text{KHCO}_3$.

S. MORGULIS

Casein: acid casein and rennet casein, and the conversion of the former into the latter. CH. PORCHER. *École Nationale Vétérinaire, Lyon. Chimie et industrie* 19, 589-98, 809-16(1928); cf. C. A. 20, 3019.—Casein is a perfectly definite compd. of const. chem. compn, being of all the proteins (with the exception of crystd. albumin), the one that is most easily prepd. in a pure state. It occurs in milk in the form of a Ca caseinate-Ca phosphate complex. The manuf. of acid casein is based on a pptn. (not a true coagulation) of free casein (which may be considered as an insol. acid) by acidifying to the isoelec. pt ($p_{\text{H}} = \text{approx. } 4.6$); and when this reaction is carried out with proper precautions in the lab. and the ppt. is adequately purified, the product is identical, whether obtained by souring, HCl or other acid and practically free from inorg. constituents. The differences observed in practice in caseins obtained by different acid processes are due to imperfections in the method of treatment and purification, in consequence of which the products contain varying amts of impurities. From a study of the synthetic systems Ca caseinate-Ca phosphate, Ca caseinate- CaCl_2 and Ca caseinate- CaCO_3 , P. shows that the production of rennet casein proceeds in 2 stages: (1) proteolysis by the rennet of the Ca caseinate into sol. Ca paracaseinate (with splitting off of a sol. proteose equiv. to 4-5% of the wt. of the casein), and (2) pptn. or coagulation of the Ca paracaseinate by sol. Ca salts which are always present, at least in traces. The coagulum or ppt. obtained from milk and from a synthetic Ca caseinate-Ca phosphate complex contains practically the whole of the Ca phosphate (ash 7% or over according to the technic and care taken in purifying and washing); with a synthetic Ca caseinate- CaCl_2 system the ash

is reduced to 3.97%, while with a Ca caseinate CaCO_3 system it is only 3.60%. The last-mentioned coagulum is the most plastic, showing that plasticity is not due to the inorg. constituents; this is further supported by the fact that free paracasein (prepd by dissolving rennet casein and pptg. with acid at the isoelec. pt.) can be obtained almost free from ash (0.95%) and is highly plastic. Since acid casein is more or less impure free casein, dissolving in excess Ca(OH)_2 and neutralizing the excess Ca(OH)_2 with H_3PO_4 reconstitutes the Ca caseinate Ca phosphate complex which, on treating with rennet, gives rennet casein identical with that obtained directly from milk. On the other hand, since casein is proteolyzed by rennet, rennet casein cannot be converted into acid casein.

A. PAINÉAU-COUTURE

Hormones and vitamins. Apropos a new denomination for vitamins. (MME.) L. RANDOIN AND H. SIMONNET. *Bull. soc. chim. biol.* 10, 745-56(1928).—A review and discussion of recent conclusions with reference to hormones and vitamins are given. The hormones as excitors are called *endhormones*, and the vitamins are called *exhormones*.

L. W. RIGGS

Pepsin. H. PÉNAU AND J. PLÉ. *Bull. soc. chim. biol.* 10, 779-83(1928).—The object of this study was to det. the results of using acetone instead of alc. as an agent for pptg. pepsin. Five cc samples of a 10% aq. soln. of pepsin were placed in weighed centrifuge tubes and the p_{H} readings of the samples were adjusted to 1.03, 2.5, 3.6, 4.7, 5.4, 6.0 and 7.0. To each tube was added 20 cc. of acetone with brisk agitation, when the tubes were corked and allowed to stand from 0 to 48 hrs. before centrifuging at high speed until the liquid cleared. The liquid was poured off and the tubes with the pptd. pepsin were dried in a desiccator over P_2O_5 with a vacuum of 2 mm. Hg and were weighed. The pptd. pepsin was tested for pepsinic activity by the method of the Codex. The wt. of the ppt. obtained was slightly less than that of the pepsin used, indicating a sparing soly. in acetone. At p_{H} 1.03 the ppt. was insol. in 0.9% NaCl soln. and completely inactive. At p_{H} 2.5, which is near the isoelec. point of pepsin, the activity was entirely conserved even after 48 hrs. of contact with acetone. At p_{H} 3.6, 4.7, up to 48 hrs. and 5.4 up to 15 hrs. of contact with acetone, the wts. and activities are practically the same as at p_{H} 2.5. Beyond 15 hrs. of contact with acetone at p_{H} 5.4 the activity of the pptd. pepsin begins to decrease. At p_{H} 6.0 the av. activity of the pptd. pepsin decreased 50% after 1 hr. of contact with acetone, and at a p_{H} of 7.0 this decrease was 90%.

L. W. RIGGS

Limit of degradation of the lactotyrynes by trypsin. S. POSTERNAK. *Compt. rend.* 186, 1762-5(1928).—From the products of tryptic digestion of casein it is possible to isolate the α , β and γ lactotyrynes (cf. *C. A.* 21, 1281, 2278) in addn. to a polypeptide having the formula $\text{C}_{48}\text{H}_{100}\text{N}_{11}\text{O}_{42}\text{P}_4$, and which represents the ultimate product of degradation of the lactotyrynes by trypsin. No other oxamino acid than serine was found among the fragments of hydrolysis.

L. W. RIGGS

Action of different races of beer yeast on the blood sugars. E. J. BIGWOOD AND A. WUILLOR. *Compt. rend. soc. biol.* 99, 347-9(1928); cf. *C. A.* 21, 1468; 22, 2177, 2588.—The disagreements in the exptl. results of Fontes and Thivolle and the authors are attributed to particular sp. action of different races of yeast. **Nonfermentable residue of the blood serum or plasma.** *Ibid* 349-52; cf. *C. A.* 22, 2178.—The total glucemia was practically the same whether H_2WO_4 or Zn(OH)_2 was used as a defecating agent. An unfermentable residue remains after defecating with Zn(OH)_2 , but not with H_2WO_4 . **Proteinic sugar of the blood.** *Ibid* 352-6; cf. *C. A.* 22, 2178.—The difference of the reducing powers before and after acid hydrolysis of the blood serum does not det. the proteinic sugar of the serum.

L. W. RIGGS

Enzymes of oil-bearing seeds. X. Glycerophosphatases. O. FERNÁNDEZ AND A. PIZARROSO. Facultad de Farmacia de Madrid. *Anales soc. españ. fís. quim.* 26, 118-21(1928); cf. *C. A.* 15, 3852.—Glycerophosphatase, discovered by A. Némec (*C. A.* 13, 2904) in seeds of various plants, was investigated in order to complete data on enzymes of oil-bearing seeds. The enzyme which splits off glycerophosphoric acid was found in many oil seeds. The activity of the enzyme is increased by slight acidity, as Némec has shown. It was not possible to prove the favorable effect of glycerol; in fact it tends to decrease rather than increase the activity of the enzyme. E. M. S.

Effect of some of the chemical constituents of tubercle bacilli on the protoplasm of *Ameba dubia*. PAUL REZNIKOFF. Cornell Univ. Med. Coll. *J. Exptl. Med.* 48, 193-7(1928).—Protein fractions derived from tubercle bacilli are toxic to the interior of *Ameba dubia* but have no action on the plasmalemma. Phosphatide fractions dissolve the plasmalemma but have no effect on the internal cytoplasm. The fatty acid fraction has a marked solvent action on the plasmalemma when brought into contact with the surface of the cell. When injected it may slowly penetrate the cytoplasm to dis-

solve the contiguous plasmalemma. The polysaccharide fraction has no effect upon the surface membrane or upon the internal cytoplasm of *Ameba dubia*. C. J. WEST

Rapid formation of adipocere during cadaveric putrefaction. ET. BARRAL. *J. pharm. chim.* 7, 486-7(1928).—See C. A. 22, 969. S. WALDBOTT

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

Urine analysis. A. JOLLES. *Arch. Pharm.* 265, 717-20(1927); cf. Piorkowski, *Ibid* 264, 460.—When thymol is used as a preservative there is risk that erroneous results will be obtained in the Obermayer, Jaffé or Salkowski tests. The violet color due solely to the thymol is, however, easily distinguished as being such. Piorkowski recommends Spiegler's test for albumin, but this test sometimes gives a positive indication with normal urine, and sometimes fails to indicate albumin even when present, because there is a lack of NaCl in the urine. The author recommends a modified test, details of which are given, but suggests that reliance should not be placed on a single reagent. As confirmatory tests the ferrocyanide, AcOH, sulfosalicylic acid and the modified Spiegler are recommended, the last of which is the most sensitive. B. C. A.

Alcoholic potassium hydroxide as a microchemical reagent for starch and aleurone. FRITZ NETOLITZKY. *Festschrift A. Tschirch* 1926, 362-5; *Chem Zentr.* 1927, I, 2933.—Starch grains are altered by concd. alc. KOH only when the latter is warm, and different types of starch change at different rates. Aleurone granules in alc. KOH assume at first a globoid appearance, but after some time the protein crystalloids are clearly visible. By further soln. and warming, the changes progress. Alc. KOH does not attack starch, but removes fats and proteins. The residual globoids are examd. microscopically. Aleurone granules from *Bertholletia* seeds contained 13-15% ash, which consisted in turn of 35-36% P₂O₅, 8.5-9.5% CaO and 17-19% MgO. The mineral residue of 30% consisted of about 50% K₂O, which with H₃PO₄, Mg and Ca is regarded as an integrant component of the globoids. C. C. DAVIS

The clinical study of the quantitative bilirubin measurement in blood (bilirubin index) with special reference to its clinical value. KOKICHI NAKASHIMA. Imp. Univ., Kyoto, Japan. *Acta Schol. Med. Univ. Imp. Kioto* 9, 327-41(1927).—The method of Meulengracht was found most satisfactory for the detn. of bilirubin in the blood if carotemia is excluded. Blood samples were taken in the morning before food was taken. Normal bilirubin index is 1 to 5 and bilirubinuria appears when it exceeds 20. In simple icterus or with gallstones it may reach as high as 200. The bilirubin index in this condition soon reaches a max. and remains at this level until the cessation of the disease. In other liver diseases (spirochetosis icterohemorrhagica japonica, distomiasis hepatitis, carcinoma, sarcoma and cirrhosis) high values were also found. In pneumonia, hemophylia, purpura hemorrhagica, HgCl₂ poisoning, dysentery and ankylostomiasis duodenalis normal values for the bilirubin index were obtained. In one case of paroxysmal hemoglobinuria the value was slightly elevated while in a case of gastric carcinoma in which there was a liver metastasis, a high value was found. In some cases the blood bilirubin index shows a high value while visible jaundice is only slight. This offers a method for the study of latent jaundice as well as for studying the course of other liver diseases. H. J. DEUEL, JR.

A benzidine test for blood. K. SCHERINGA. *Pharm. Weekblad* 65, 712-3(1928).—The benzidine-H₂O₂ test for blood is not conclusive unless precautions are taken to insure the absence of other catalysts. Positive reactions were obtained with sand, wheat flour and talc. If the benzidine test for blood in feces is positive, the test should be confirmed by applying it to the residue obtained by evapg. the Et₂O ext. of a sample acidified with AcOH. A. W. DOX

Basal metabolism. IX. Simplified calculation for gasometer gas-analysis method. W. H. STONER. *J. Lab. Clin. Med.* 12, 884-8(1927); cf. C. A. 20, 1824.—Simplified formulas are developed for calcg. the respiratory quotient and basal metabolic rate from

gas analysis and gasometric data. The formulas for the basal metabolic rate are applicable to the Harris-Benedict, Dreyer or Aub and DuBois standards. **X. Simplified data blank for gasometer gas analysis.** *Ibid* 13, 164-71.—A blank for recording the data and calcs. described in the foregoing paper is described and illustrated. H. G.

A method of obtaining alveolar air from normal dogs and a comparison of the carbon dioxide tensions of alveolar air and arterial blood. RALPH G. SMITH AND PETER HEINBECKER. Washington Univ., St. Louis. *Am. J. Physiol.* 84, 271-82(1928).—Dogs were trained to lie quietly wearing a plaster of Paris mask to which valves were so connected that a portion of the air last expired was automatically collected. Alveolar air collected in this way was compared with arterial blood collected from the left ventricle with respect to CO_2 and O_2 . Equil between the air and blood was shown to exist for CO_2 but not for O_2 . J. F. LYMAN

Simultaneous determination of the pulmonary and systemic circulation times in man and of a figure related to the cardiac output. W. F. HAMILTON, JOHN W. MOORE, J. M. KINSMAN AND R. G. SPURLING. Univ. Louisville. *Am. J. Physiol.* 84, 338-44 (1928).—Na tetraiodophenolphthalein was injected into a vein in man and its appearance and reappearance in blood from the radial artery were timed. In dogs injection was into the right ventricle and appearance in the left ventricle. J. F. LYMAN

A simple slide rule for the calculation of respiratory quotients. W. A. M. SMART. *Proc. Physiol. Soc., J. Physiol.* 64, ix(1927).—This slide rule is designed for the rapid detn. of the respiratory quotient from the % compn. of the inspired and expired air. J. F. LYMAN

A characteristic reaction for bilirubin. LODOVICO BECCARI. *Boll. soc. ital. biol. sper.* 3, 332-3(1928).—B. studied the effect of various oxidizing agents on bilirubin in acid and alk. solns. and detd. the exact conditions in which bilicyanin is formed regularly. He combined the action of ammoniacal ZnCl_2 with that of iodine (soln. iodine-iodide) in such a manner that the oxidation of the pigment was arrested at the blue stage. A small amt. of ZnCl_2 was added to the bilirubin followed by a few drops NH_4OH and then a dil. soln. of iodine-iodide was poured drop by drop until a bright green-blue coloration was formed which had the characteristic spectrum of bilicyanin in alk. soln. This consisted of three well-defined absorption bands. The first very intense in the red region touched the line C ($\lambda = 656$) with limits λ 658- λ 627; the second, not so intense, in the yellow, covered the line D ($\lambda = 589$) with limits λ 658- λ 627; the third began at the line E ($\lambda = 527$) and in concd. solns. covered the entire violet region; in weak solns. it reached $\lambda = 503$. Further oxidation of bilicyanin with iodine-iodide changed the color to a yellowish rose, with an intense green fluorescence. P. M.

The determination of the sodium content of small amounts of serum or heparinized plasma by the iodometric method. M. DOROTHY ROURKE. Harvard Univ. *J. Biol. Chem.* 78, 337-44(1928).—By modifications of the Kramer-Gittelman method for the detn. of Na, R. was able to det. Na in serum or plasma without the removal of proteins, on either ashed or unashed samples. The detn. could be made on as little as 0.3 g. plasma or serum. C. RIEGEL

Method of determination of the respiratory elimination of acetone by man. R. COQUOIN. *Compt. rend.* 186, 1581-2(1928).—The normal human subject after 12 hrs. fasting and complete repose was given by mouth 5 cc. of acetone dild. with 120 g. of sweetened water (10%). After 15 min., 30 min. and thereafter at 30 min. intervals the expired air for periods of 5 min. was passed from a Tissot mask into a Cloez bubbler contg. NaHSO_3 20 g., Na_2SO_3 5 g. and H_2O up to 120 cc. The acetone was distd. from the sulfite soln. in a current of steam and estd. iodometrically. During the first 3 hrs. following the ingestion, 2 to 3 mg. of acetone were recovered from the expired air of a 5-min. period and 1.0 to 1.8 mg. were recovered during a 5-min. period after 6 or 7 hrs. L. W. RIGGS

Detection by micro-incineration of sodium and potassium in the cytoplasm of the red corpuscles. A. POLICARD AND D. PILLET. *Compt. rend. soc. biol.* 99, 85-6(1928).—The Na and K are converted to sulfates. This involves a somewhat complicated procedure of treating the corpuscles on the slide with SO_3 to avoid displacing certain elements of the corpuscles. L. W. RIGGS

Micro-estimation of glycogen in the liver. H. BIERRY AND B. GOUZON. *Compt. rend. soc. biol.* 99, 186-8(1928).—The tissue is dissolved in 35% KOH soln. and autoclaved at 120° for 30 min. After cooling the KOH is neutralized with an excess of HCl and the liquid again autoclaved at 120° for 30 min. The excess of acid is then neutralized and the proteins are removed by means of $\text{Hg}(\text{NO}_3)_2$ and the glucose is detd. by the micro-method of Bierry and Gruzewska. L. W. RIGGS

Micro-estimation of glucose: application to the determination of liver glycogen.

H. BIERRY AND (MLE.) L. GOIRAN. *Compt. rend. soc. biol.* **99**, 253-5(1928).—The method consists in heating, for 6 min. in the boiling water bath, 3 cc. of liver ext. with 6 cc. of cuproalkaline liquid and detg. the Cu_2O formed by the Mohr-Bertrand method.

L. W. RIGGS

Micro-estimation of glucose. L. DE SAINT-RAT. *Compt. rend. soc. biol.* **99**, 474-5 (1928).—The method of Bierry and Goiran (cf. preceding abstr.) compared with the author's method (cf. *C. A.* **14**, 3091) shows slightly higher figures for the latter. This difference is attributed to the difference in reduction time in the 2 methods.; L. W. R.

Detection of acetone. ANDREW WALLHAUSER. *J. Am. Med. Assoc.* **91**, 21 (1928).—This clinical method depends on the formation of a ppt. in a hanging drop of Scott-Wilson reagent suspended from the mouth of a container holding blood or urine.

L. W. RIGGS

Comparison of the colorimetric determination of adrenaline by Folin, Cannon and Denis, and by Suto and Inouye with the rabbit intestine segment method. TAKEO KOJIMA AND SHIDZUKA SAITO. *Tôhoku J. Exptl. Med.* **10**, 528-45(1928).—The values yielded by the two methods did not coincide, the ratio of the colorimetric to the biologic figures ranging between 1 to 1.1 and 1 to 2.1 in 5 expts. Suto's ext. cannot be simply applied to the rabbit intestine strip. **Experiments on the medulla of the bovine suprarenal gland.** *Ibid* 546-59.—By the application of liquid air for pulverizing and mixing the medullary tissue of the suprarenal body uniform material was obtained for the tests. Both methods have the same valuation for extg. and estg. the adrenaline in the bovine suprarenal medulla.

L. W. RIGGS

Differentiation of eosinophile and pseudo-eosinophile cells by means of peroxidase reaction (copper method) on the smear and in the counting chamber. HIROSHI SAKURADA. *Tôhoku J. Exptl. Med.* **11**, 1-5(1928). **Differentiation of eosinophile and pseudo-eosinophile leucocytes in rabbit blood by use of the oxidase reaction.** (Smear method and counting chamber method.) KENJI SHOJI. *Ibid* 6-9. The proper time for oxidase reagent (Winkler-Schultze) and peroxidase reagent (copper method) to be used. KAZUE SUZUKI. *Ibid* 10-3.—The papers comprise the 13th, 14th and 15th reports of the peroxidase reaction. The last paper refers to the keeping qualities of the reagents.

C—BACTERIOLOGY

C. B. MORREY

The relation of combined nitrogen to the physiological activity of *Azotobacter*. A ZOOND. *Brit. J. Exptl. Biol.* **4**, 105-13(1926); *Physiol. Abstracts* **12**, 189.—The amt. of atm. N fixed in culture solns. of *Azotobacter* is decreased by increasing the concns. of nitrate, amino acid or peptone available. The addn. of sterile unheated plant exts. at first increases the amt. fixed, probably because it stimulates cell multiplication, but

heavy application checks this assimilation. *Azotobacter* would seem, therefore, to prefer to use combined N when such is available. H. G.

The production of gluconic acid by the *Penicillium luteum-purpureogenum* group. II. Some optimal conditions for acid formation. H. T. HERRICK AND O. E. MAY. *J. Biol. Chem.* 77, 185-95(1928).—The effect of varying the temp., glucose concn. and inorg. nutrient media on the production of gluconic acid by *Penicillium* was studied. A temp. of 25°, a glucose concn. of 20 to 25%, and a nutrient salt soln. contg. 0.25, 0.05, 0.1 and 1.0 g. of $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$, KCl, Na_2HPO_4 , $12\text{H}_2\text{O}$ and NaNO_3 , resp., per l. of soln., gave the optimal results. ARTHUR GROLLMAN

Typical poisons for the metabolism of yeasts. WOLFGANG HEUBNER AND ROLF MEIER. *Nachr. Ges. Wiss. Gottingen Math. physik Klasse* 1927, 115-24.—A study of cell poisons was made by means of a manometric measurement of changes in O_2 consumptions and CO_2 evolution. The work was done with distillery yeasts, bottom yeasts and torula suspended in a soln. of 1% K_2HPO_4 and 3% $\text{C}_6\text{H}_{12}\text{O}_6$ at 28°. No increase in the life activity as indicated by O_2 consumption could be attributed to traces of poisons. A series of tabulated results is given for the following substances: Ag_3PO_4 , HgCl_2 , $\text{K}_2\text{Cr}_2\text{O}_7$, As_2O_3 , $\text{C}_6\text{H}_5\text{OH}$, quinine chloride, chloropicrin, mustard oil, cantharidin, histamine chloride and Me arsinoxide. N. A. LANGE

The antibacterial and anticomplementary action of bile. W. PFANNENSTIEL. *Z. Immunol.* 52, 445-67(1927).—Pure bile itself is not an ideal culture medium for typhoid bacilli, but when combined with serum the antibacterial action of both substances is inhibited and the mixt serves as an excellent enrichment medium. The higher the bactericidal action of the serum the higher the concn. of bile which must be used to neutralize this action. The bactericidal action of bile begins to be lessened when dild. 1:10. Bile acid salts alone inhibit the antibacterial action of serum but not urea. The destruction of the antibacterial action of serum is assocd. with a destruction of hemolytic complement function. The action of bile and bile acid salts rests on physicochem. changes which are produced on the colloidal system of proteins and lipoids of serum. JULIAN H. LEWIS

The octoplasma of bacteria. (The Gram stain, the nucleus of bacteria and the chemistry of disinfection.) Also remarks on the work of Gutstein. JOSEF SCHUMACHER. *Centr. Bakt. Parasitenk. I Abt. Orig.* 107, 161-80(1928).—This is a discussion of the previous work of Schumacher and of Gutstein (*C. A.* 21, 935). JOHN T. MYERS

To what extent are the numbers of typhoid bacilli influenced by osmosis and hydrogen-ion concentration during passage through the intestinal canal? KARL W. CLAUBERG. *Centr. Bakt. Parasitenk. I Abt. Orig.* 107, 184-9(1928).—The no. of typhoid bacilli gradually decrease from the duodenum to the rectum, apparently because of higher salt and acid concn. in the rectum. JOHN T. MYERS

The influence of the sodium salt of yatren on rabies virus. BORIS ABADJEFF. Robert Koch Inst., Berlin. *Centr. Bakt. Parasitenk. I Abt. Orig.* 107, 202-5(1928).—Equal vols. of fixed rabies virus (10% brain emulsion in isotonic NaCl) and 5% yatren mixed and kept at 37° for 3 hrs. became avirulent, as tested by subdural guinea-pig injections. JOHN T. MYERS

The identification of a number of strains of milk streptococci, with special reference to the isolation of *Streptococcus agalacticus* of Guillebeau. M. KLIMMER, H. HAUPT AND ELM. ROOTS. Veterinary Hygienic Inst., Leipzig. *Centr. Bakt. Parasitenk. I Abt. Orig.* 107, 206-31(1928). JOHN T. MYERS

The destruction of lower alkylamines by bacteria. ALEXANDER JANKE. Techn. Hochschule, Wien. *Centr. Bakt. Parasitenk. II Abt.* 74, 25-6(1928); cf. *Ibid* 71, 193-232(1927).—The term, "primoramino-microbes," is better than the term, "protamine bacteria." JOHN T. MYERS

The influence of radium on the metabolism of bacteria concerned in the nitrogen cycle in nature. JULIUS STOKLASA AND J. KŘÍČKA. *Centr. Bakt. Parasitenk. II Abt.* 74, 161-83(1928).— β - and γ -Rays depress the transformation of elementary N to nucleoproteins and albumins in the cells of *Azotobacter chroococcum*. α -Rays decrease the activity of ammonifying bacteria. β - and γ -Rays favor the action of proteolytic enzymes. Below a concn. of 28 ME, Ra emanation has no effect on denitrification; above this, it is a depressant; β - and γ -rays have no effect. Weak β -radiation stimulates bacterial hydrolytic and autolytic processes, while strong radiation gradually inhibits them. When *Azotobacter* acts on glucose the amt. of CO_2 is increased by α - and decreased by β - and γ -rays, the amt. of lactic acid is increased by all, the amt. of alc. is decreased by α and increased by β and γ , the aldehyde is increased by all, the AcH is increased by α and decreased by β and γ , and the HCOOH is increased by α and decreased by β and γ . Splitting of proteins by enzymes of denitrifying bacteria is little

influenced by α but markedly increased by β and γ . The N appears chiefly as amides and diamino compds. This process is of considerable significance in pathology and therapeutics.

JOHN T. MYERS

The occurrence of phytase in some yeasts and *Aspergillus oryzae*. CHŪJIRŌ SHIMODA. *Centr. Bakt. Parasitenk. II Abt.* 71, 232-47(1927).—Phytin from rice bran is a Ca-Mg salt of inositol-hexaphosphoric acid. On purification it splits off Mg more easily than Ca. It is decompd. by drying at 100° in *vacuo*. A soln. gives a yellow ppt. on warming with acid NH_4 molybdate. The yeasts, *Pichia farinosa* and *Mycoderma A. Takagashi* and *Aspergillus oryzae*, thrive with phytin as the only source of N, and contain phytase.

JOHN T. MYERS

The decomposition of agar, xylan, etc., and the sugars related to these hemicelluloses by *Vibrio andoi* (n. sp.). K. AOI AND J. OIKURA. Imperial Agr. Expt. Sta., Tokio. *Centr. Bakt. Parasitenk. II Abt.* 74, 321-33(1928).—A new aerobic microorganism was sepd. from a sub-culture of bacteria which decomp. cellulose. In pure culture it does not act on cellulose, but readily attacks xylan, agar, konjac-mannane and starch, utilizing these as a source of C for growth. It also utilizes cellobiose, xylose, galactose, glucose, mannose and fructose, but not peptone, as a source of C. NH_4 salts or NO_3 are adequate as a source of N, but peptone is not. Galactose inhibits its growth at concns. above 0.03%, and peptone above 0.25%. An infinitesimal quantity of an unknown substance is essential to growth, which is present in Witte peptone. The organism may be of value in cellulose decompn. by removing xylan from raw materials such as straw, making it more accessible to other organisms.

JOHN T. MYERS

The action of iron, zinc and copper salts on *Aspergilli*. MAX ROBERG. *Centr. Bakt. Parasitenk. II Abt.* 74, 333-70(1928).—Nutrient materials were freed from heavy metals, not by absorption with CaCO_3 , but by repeated recrystn. or distn., thus avoiding changes. *A. niger*, *fumigatus* and *oryzae* fail to grow in the absence of Fe or Zn. Cu stimulates fruiting. *A. niger* does not become black in the absence of Cu. The bibliography is very extensive.

JOHN T. MYERS

A thermophile coagulating milk under practical conditions. R. V. HUSSONG AND B. W. HAMMER. *J. Bact.* 15, 179-88(1928).—A thermophile was isolated from skim milk, which rapidly coagulated milk at 71°, because of formation of lactic acid of the *d* type. Volatile acid production was low. It only slightly increased the sol. N of the milk. It is believed to be an undescribed species and the name *Bacillus calidolactis* is proposed.

JOHN T. MYERS

A strain of *Clostridium welchii* causing abnormal gassy fermentation in Emmentaler or Swiss cheese. WM. R. ALBUS. *J. Bact.* 15, 203-5(1928).—A non-pathogenic strain of *Cl. welchii* was isolated from a Swiss cheese which showed abnormal gassy fermentation. Other factors than the presence of the gas-producing organism play an important part in detg. the type of gassy fermentation in cheese.

JOHN T. MYERS

The decomposition of cellulose by aerobic bacteria. RENÉ J. DUBOS. New Jersey Agr. Expt. Sta. *J. Bact.* 15, 223-34(1928).—A rapid and abundant growth of aerobic cellulose-splitting bacteria is obtained by the use of the following medium which is simple and very specific: NaNO_3 0.5, K_2HPO_4 1.0, $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ 0.5, KCl 0.5, $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ 0.01, distd. water 1000 g. Five cc. of this medium are placed in test tubes contg. a strip of filter paper partly immersed. The slightly alk. reaction of the medium (p_{H} 7.5) favors the growth of bacteria and retards that of fungi. The low concn. of N salts shortens the incubation period of bacteria, since, in almost all cases, cellulose decompn. can be recorded after 36 to 72 hrs. at 28°. Growth is obtained when only 1 or 2 cells are used for inoculation, making possible the use of the diln. method for detg. the nos. of cellulose bacteria and for isolating them in pure culture. Pure culture of organisms belonging to 3 different physiol. groups have been isolated by this method: (a) strict aerobes, unable to utilize any C compds. tested except cellulose; (b) strict aerobes, cellulose decomposers growing well on starch agar, but not on nutrient agar; (c) facultative anaerobes, cellulose decomposers, growing well in all ordinary media. For the aerobes, NH_4 salts and nitrates seem satisfactory sources of N. Peptone retards the growth considerably.

J. T. M.

The fermentation of maltose by *Bacterium pullorum*. PHILLIP R. EDWARDS. Kentucky Expt. Sta. *J. Bact.* 15, 235-43(1928).—When unheated maltose soln. is added to serum water which has been previously sterilized, *Bact. pullorum* does not ferment the sugar within 24 hrs., but upon prolonged incubation acid may be produced. It seems that *Bact. pullorum* does not attack dextro-maltose but may produce acid from the products of alk. hydrolysis of maltose, since cultures free from fermentable sugar may reach an alk. of p_{H} 8.15, which can hydrolyze maltose. Of 88 strains employed, none could ferment dulcitol; hence it is safer in differentiating *B. pullorum* from *B. sanguinarum* than is maltose.

JOHN T. MYERS

Some conditions affecting the production of gelatinase by proteus bacteria. ALICE T. MERRILL AND W. MANSFIELD CLARK. Hyg. Lab., U. S. Public Health Service. *J. Bact.* 15, 287-96(1928).—Results in investigations of the production of gelatinase by bacteria can be duplicated in synthetic media but not in peptone broth. A no. of synthetic media were tried. In the absence of both Ca and Mg, no gelatinase was demonstrable, which cannot be explained by the slight resulting decrease in no. of organisms. In the presence of Ca alone the production of gelatinase was small; with Mg alone it was only fair as compared with the amt. formed in the presence of both. *Proteus* can produce gelatinase under anaerobic conditions when glucose or small quantities of nitrate are added to a lactate synthetic medium. There is a good bibliography.

JOHN T. MYERS

Bacterial metabolism. The influence of phosphate buffer in carbohydrate-free and in glucose-containing media. CHARLES F. SLANETZ AND LEO F. RETTGER. Yale Univ. *J. Bact.* 15, 297-317(1928).—Phosphate buffer in reasonable amts. (1%) will in many instances maintain a sufficiently low level of H-ion concn. to permit nitrogenous changes in the substrate as though no utilizable carbohydrate were present. This ability differs with bacterial species or even with members of the same species. The methods used in the study of N metabolism were comparative detns. of total protein, non-protein, NH_3 , amino and polypeptide N and biuret.

JOHN T. MYERS

The effect of hydroxyl-ion concentration on the thermal death rate of *Bacterium coli*. R. P. MYERS. Cornell Univ. *J. Bact.* 15, 341-56(1928).—Different buffer mixts. of approx. the same p_H exert very different germicidal effects; the effect of p_H can only be compared with a single buffer system. Increase in p_H on the alk. side of neutrality increases the power of a given soln. to destroy *B. coli* at a given temp. J. T. MYERS

The carbohydrate metabolism of *Ps. aeruginosa* (*B. pyocyaneus*). H. J. SEARS AND M. F. GOURLEY. Univ. of Oregon, Med. School. *J. Bact.* 15, 357-66(1928).—*Ps. aeruginosa* produces an acid reaction in glucose peptone, and in glucose peptone meat ext media when the N content of the medium is kept low. Only a small quantity of glucose is used. When the N content is high (2% or more of peptone) no acid reaction is produced but large amts. of glucose are utilized. When other sugars are used in place of glucose an acid reaction is not produced even when N is low. Many sugars can be utilized, since while *Ps. aeruginosa* will not grow in an NH_4 tartrate mineral-salt medium, the addn. of such sugars causes good growth. JOHN T. MYERS

The electrophoresis of diphtheria bacilli. I. Some relations between the virulence, toxigenicity and electrophoretic mobilities of diphtheria bacilli. L. B. JENSEN AND I. S. FALK. Univ. of Chicago. *J. Bact.* 15, 367-411(1928).—Five avirulent and 45 virulent strains of diphtheria bacilli were indistinguishable when tested on the following substances: fucose, *d*-arabinose, *a*-glucoheptose, *a*-mannoheptose, cellulose, melibiose, trehalose, melezitose, rhamnose, xylose, levulose, glucose, galactose, mannose, sucrose, lactose, maltose, raffinose, inulin, starch, glycogen, dextrin, dulcitol, erythritol, *d*-mannitol, adonitol, *d*-arabitol, glycerol, arbutin, α -methyl glucoside, salicin, amygdalin, mannonic acid lactone, gulonic acid lactone, glucosamine-HCl, glucose, levulose, galactose, maltose, dextrin and glycerol were fermented alike by the 50 strains. Acid was not produced from any of the other substances except glucosamine-HCl and 5 virulent and 1 avirulent strain failed to ferment it. Measurements of electrophoretic potentials on 48-hr. veal broth cultures of toxogenic strains gave p. ds. of 4.2 to 1.0 μ per sec. with an av. of 3.4 μ . Similar measurements on avirulent strains which ferment glucose gave a p. d. of 12.1 μ . Non-fermenting avirulent strains gave p. d. of 7.9 to 10.0 μ . Some culturally typical but avirulent and non-toxogenic gave a p. d. of 4.4 to 6.2 μ . These p. ds. were not due to differences in p_H . Distd. water suspensions of corynebacteria washed 3 times in distd. water gave the following potentials: avirulent strains, 20 to 34 per sec.-110 v., virulent strains 2.6 to 11.0 per sec. There was no apparent parallism between the min. fatal dose of washed bacilli suspended in distd. water and their p. d. in the same menstruum. The toxigenicity is inversely proportional to the p. d. Salted out, purified, toxic materials depress p. d. in a quant. manner, but this has little significance till toxin can be better purified. II. Microelectrophoresis and the differentiation of virulent and non-virulent diphtheria bacilli. L. B. JENSEN AND I. S. FALK. Univ. of Chicago, AND F. O. TONNEY AND J. L. WHITE, Dept. of Health, City of Chicago. *Ibid* 413-9.—A p. d. of 5.0 μ per sec. was taken as the dividing line between virulent and non-virulent strains. In a series of 105 unknown cultures, 88 were virulent by both the electrophoretic and the guinea-pig tests, 13 were avirulent by both tests and 4 were virulent by electrophoresis and non-virulent by guinea-pig tests. Of the 4 cultures which did not agree, 3 had a p. d. of 4.8 and the other 4.2 μ per sec., thus being close to the avirulent type. III. The development of a simplified technic for electrophoretic

measurement of the virulence of diphtheria bacilli. I. S. FALK, L. B. JENSEN AND J. H. MILLS. Univ. of Chicago. *Ibid* 421-50.—Two methods are described, one using a special cell and the other, capillary tubes, the latter being the simpler will be described. Transfer 3-6 sep. colonies from 12- to 24- hr. Loeffler cultures directly to a few drops of distd. water, making a turbidity of about 1 billion per cc. The capillary tube should be a little longer than the distance between the electrodes and have a diam. of 2 to 3 mm. It is filled by capillarity and laid across the electrodes. The cell is filled with distd. water always to a definite level. Focus on the middle of the capillary. Apply a current of 25 to 50 v., and note the time required for the organisms to pass a definite distance. Reverse the direction of the current and read again. Make 10 or 12 readings. Any d. c. source of current can be used. Any microscope with a calibrated head on the fine adjustment screw will serve. A Sedgwick-Rafter ruling calibrated in μ is placed in the ocular. The cell should be wired to the source of current through a reversing switch with a small ammeter and voltmeter in circuit. The current flowing should be less than 10 milliamperes. An extra main switch is convenient. Under the influence of the external elec. field all the water moves toward the cathode at a velocity practically without a gradient across the diameter of the tube. Bacteria being negatively charged move toward the anode. Under a given set of conditions, the observed velocity is the difference between the endosmotic streaming of the water (End._w) and the electrophoretic velocity of the bacterium (Elect._b). Thus, observed motility = End._w - Elect._b. Hence the observed motility varies inversely with its true mobility.

JOHN T. MYERS

The practical application of the direct oxidase reaction in bacteriology. J. GORDON AND J. W. McLEOD. Univ. of Leeds. *J. Path. Bact.* 31, 185-90(1928).—Most of the bacteria which grow well only in the presence of O contain a thermolabile direct oxidase system which can be revealed by bringing the colonies in contact with a 1% soln. of dimethyl-*p*-phenylenediamine-HCl and subsequently exposing them to air. The dye is absorbed by the colonies and rapidly oxidized through red to black. Colonies if fished at the red stage are viable; hence a mixed plate can be flooded and reacting colonies fished. This applies especially to isolation of the gonococcus, which reacts.

JOHN T. MYERS

Further investigations on selective bactericidal action. E. ASHLEY COOPER AND JOHN MASON. Univ. of Birmingham. *J. Path. Bact.* 31, 343-51(1928); cf. *C. A.* 21, 3925.—Germicides can be divided into chem. and physico-chem. types. Dyes such as brilliant green, malachite green and crystal violet behave as chem. germicides, attacking *B. coli* preferentially to the *B. pyocyaneus* group. *B. mesentericus* is more sensitive to the physico-chem. germicides such as phenol which act by coagulation, racemization, etc. *B. proteus*, although more susceptible than *B. coli* to heat, has a greater resistance to phenol and alc. The thermophiles are highly resistant to physico-chem. disinfectants, but this is extended to certain chem. germicides as H₂O₂ and benzoquinone, although they are highly susceptible to certain dyes. Substances exerting a chem. reducing action are more highly germicidal to *B. coli* under aerobic than under anaerobic conditions. It is this secondary factor of O tension which makes reducing agents fall into the physico-chem. group instead of the expected chem. group. Under all exptl. conditions phenol attacks the pyocyaneus group preferentially, indicating that the selective action depends on internal colloidal conditions of the organism rather than on environmental factors. Picric acid and quinone behave alternatively as physico-chem. and chem. germicides according to exptl. conditions. Perhaps they have the power of either denaturing and acting chemically with cell constituents and either process may predominate under given sets of conditions.

JOHN T. MYERS

The influence of NaCl on the growth and metabolism of yeast (Speak, *et al.*) 16.

D—BOTANY

THOMAS G. PHILLIPS

A chemical study of the development of cotton bolls and the rate of formation of gossypol in the cottonseed. WILLIS D. GALLUP. *J. Agr. Research* 36, 471-80(1928); cf. *C. A.* 21, 3218.—Cotton bolls picked at different stages of development show rapid changes in chem. compn. from the time the boll is first formed until ready to open. The young bolls are high in ash, N and carbohydrates. As they mature fat and crude fiber increase. Crude fiber also increases slightly after the bolls are open. The compn. of immature bolls seems to depend upon a number of factors, such as age of the boll,

time of maturation, climatic conditions during growth, and possibly nutrition of the plant. Cotton lint is variable in compn and although the mature lint is composed mostly of crude fiber other materials may be of importance. The development of oil and gossypol in the cotton seed occurs at about the same time and during a short and well-defined period of growth. The function of gossypol seems to be associated in some way with oil formation. M. S. ANDERSON

The newly discovered presence of coumarin in native plants. ALEXANDER V. LINGELSHIEIM. *Festschrift A. Tschirch* 1926, 149-54; *Chem. Zentr.* 1927, I, 2914-5.—By microsublimation with NH_3 , coumarin was found in *Prunus avium*, *Prunus fruticosa* and *Prunus fruticosa* Cerasus. Besides NH_3 , Et_2O , CHCl_3 and CS_2 vapors are suitable for bringing out the odor of coumarin. By steeping the leaves in boiling water, the ability to form coumarin is lost, whereas steam and freezing mixts promote the formation of coumarin. According to the opinion of L., the presence of coumarin in varieties of *Prunus* is an indication that they are members of some definite group. A survey of the extensive occurrence of coumarin in the plant world is included. C. C. DAVIS

The seeds of *Nerium oleander* L. HERMANN MATTHIES AND PAUL SCHUTZ. Univ. Königsberg. *Festschrift A. Tschirch* 1926, 162-73; *Chem. Zentr.* 1927, I, 2753-4.—A report of an investigation of the seeds of *Nerium oleander* L., the botanical and microscopic characteristics being described with the aid of numerous illustrations. To identify the seeds, the method prescribed by the D. A. B. V. for *Folia digitalis* was used. A bluish red zone is formed between the 2 liquids, while the upper liquid becomes after a time a delicate green. To ext. the oil, the seeds were treated with petroleum benzine (d. 0.640-0.660), and the pappus was extd. in the same way. The oil from the seeds was a clear green, while at ordinary temp. the pappus oil was turbid, an intense fluorescent green. The seeds contained 8.01% water, 17.43% fat, 2.8% N, 17.5% crude protein and 3.76% mineral substances. The oil from the seeds had a bitter taste, d_{15}^4 0.9355, n_D^{25} 1.4721, n_D^{40} 1.4669, acid no. 2.5, sapon. no. 206.8, Reichert-Meissl no. 16.30, Polenske no. 0.40, Hubl I no. (after 2 hrs.) 105.2, (after 18 hrs.) 108.6, Ac no. 12.5, Hehner no. 92.09, refraction of the Hehner fatty acids n_D^{40} 1.4595. There was 2.12% unsaponifiable material. The oil of the seta has a strongly bitter taste, contains 8% unsaponifiable substances, had d_{15}^4 0.9253, n_D^{25} 1.4550, sapon. no. 182.4, Hubl I no. (after 2 hrs.) 91.4. Oleander oil is a non-drying oil. Its water-insol. fatty acids consist of 12% solid and 88% liquid acids. These were sepd. by the Pb salt-alc. process of Twitchell. The solid fatty acids had an I no. of 3.6 and are probably a mixt. of palmitic and stearic acids. Bromination indicated that the liquid fatty acids consist of about 18% linoleic acid and 82% oleic acid. The presence of a more highly unsatd. fatty acid is possible. The unsaponifiable substances of the oil contain only a phytosterol, m. 137.5° and a sitosterol. The liquid unsaponifiable part had an I no. of 130.60. C. C. DAVIS

The red and the blue coloring matter of flowers and fruits. A. P. TSAKALOTOS. Univ. Bern. *Festschrift A. Tschirch* 1926, 291-8; *Chem. Zentr.* 1927, I, 2915.—Comparative capillary and spectral analytical studies were made of flowers and fruits which had been examd. by Willstätter and his collaborators. Cellulose was used for adsorption, according to the method of Schonbein and Goppelsröder. Three groups of flowers and fruits were investigated, those which had been considered by Willstätter to contain (1) cyanidine, (2) pelargonidine and (3) delphinidine. A no. of other plants and various vines were also examd. The blue and red coloring matter of flowers and fruits, aside from colorless cell components, is accompanied by chlorophyll and yellow coloring matter. The chlorophyll zone always lies on top in the capillary-analytical sepn., followed in most cases by a colorless or yellowish zone, and below this by the anthocyanine zone. By sepn. of the latter zone and soln. of the coloring matter in EtOH, a slightly colored soln. is obtained which becomes colored on addn. of HCl or of NaOH. Spectral analysis of this soln. showed no sharp differences in the anthocyanins. Capillary-analytical sepn. showed that the coloring matter of fresh berries of the whortleberry plant is a mixt. of 2 colored substances, though this is not true of dried whortleberries. A similar difference was found between the exts. of fresh and dried fruit of *Sambucus nigra*. The coloring matter of the radish varied from that of flowers and fruits. The coloring matter of the *Alcanna* showed by spectral analysis 2 distinct zones, as with fresh whortleberries. C. C. DAVIS

The presence and the significance of manganese in plants. D. H. WESTER. *Festschrift A. Tschirch* 1926, 321-5; *Chem. Zentr.* 1927, I, 2914; cf. C. A. 18, 141.—A summary of investigations by W. on the Mn content of a few types of digitalis, Dutch seeds, flowers and varieties of soil (cf. C. A. 17, 2339), with a report of new expts.

Mushrooms have a high ash and a low Mn content. A no. of leaves gathered at Ellemore were distinguished by their high Mn content. In *Lupinus luteus* the highest Mn content was in the active parts of the plants (young shoots and flowers). Fertilization expts. showed that Mn is of great importance to plants physiologically. It had a favorable influence on the active parts of *Prunus laurocerasus*, *Brassica nigra* and *Papaver somniferum*. C. C. DAVIS

Citrus oxidases. GUIDO AJON. *Atti congresso naz. chim. pura applicata* 2, 1092-1119 (1926).—A. has identified in the rind of citrus fruits an oxidase, a peroxidase and a catalase. Furthermore the development of the 3 enzymes was followed during the ripening of the fruit. In the rind of the green fruit a peroxidase protein in nature was sepd. which the author has designated as *sichelase*. The oxidase functions in the formation of the acid and the essences of the fruit. It is also concerned in the development of the yellow color in ripening owing to its action upon the green pigment of the ring L. T. FAIRHALL

The greasewood, *Sarcobatus vermiculatus*. A range plant poisonous to sheep. C. E. FLEMING, M. R. MILLER AND L. R. VAWTER. *Nev. Agr. Expt., Bull.* 115, 1-22 (1928); cf. C. A. 22, 3002.—A chem. examn. of 6 samples of greasewood leaves showed an av. of 4% of anhyd. oxalic acid or calcd. to a H_2O -free basis, 13.6%. Saponins were absent as were any of the common alkaloids strongly pointing to $H_2C_2O_4$ as the toxic agent. Expts. with sheep proved that greasewood caused the fatal poisoning. Hungry or salt-hungry sheep will eat greasewood leaves especially in the spring when the shoots are tender and green. Well-nourished animals usually do not consume enough to cause poisoning symptoms. C. R. FELLERS

Photosynthesis. I. C. C. BALY. *Proc. Roy. Inst. Gr. Brit.* 1928, 8 pp. (reprint); cf. C. A. 21, 3649.—To synthesize 1 g. mol. of glucose requires a min. of 673,800 cal. Although plants can absorb only 260,000 cal. from red light of wave length 660μ they can synthesize sugars under the influence of light of those wave lengths. Hence some unknown factor must operate in vital photosynthesis. From lab. expts. B. concludes that surface phenomena play an important role in the process. H. R. KRAYBILL

Feeding experiments with plants at different stages of development. III. Synthesis of vitamin in corn. MAXWELL KARSHAN, FRANCES KRASNOW AND BENJAMIN HARROW. *Columbia Univ. Am. J. Physiol.* 84, 314-20 (1928).—See C. A. 22, 2770. J. F. LYMAN

Konjak mannan. TORAO OHTSUKI. *Imp. Univ., Tokyo. Acta Phytchim. (Japan)* 4, No. 1, 1-39 (1928).—A crude powder prepd. from the tubers of *Amorphophallus konjak* yielded when taken up in water and ppt. with alc. a mannan having $[\alpha]_D^{14} = -42.8$, which caused no lowering of f. p., and yielded on hydrolysis mannose and glucose in the proportion 2:1. When treated with a malt diastase, or yeast, the mannan gave a substance (Konjak mannan) with the same rotation, and yielding the same products of hydrolysis but with a viscosity 7.7 times less than the mannan. By treating with the diastase for long periods of time a trisaccharide was obtained (levidulinose) having a rotation $[\alpha]_D^{14} = -15.6$, and yielding mannose and glucose on hydrolysis. Heating at 235° with glycerol gave a dissocn. product that is much more sol. in water, of lower viscosity, and the same rotation as the original material. The particles are of the same size as a trihexosan. The substance reassociated on standing to a higher colloid, and gave on hydrolysis mannose and glucose in the proportion 2:1. The acetylated product had a mol. wt. (dtd. by cryoscopic method) corresponding to a hexoseanhydride acetate. C. RIEGEL

Distribution of manganese in plants and its importance in plant metabolism. WILFRID B. S. BISHOP. *Australian J. Exptl. Biol. Med. Sci.* 5, 125-40 (1928).—Mn was found in the ashes of 25 species of Eucalypts. Mn in Eucalypts and other plants was most concd. in those parts of the plant where there was the most intense chem. change. By controlled plant growth expts. it was shown: (a) Mn is essential for plant development. (b) The concn. of Mn must be carefully limited to obtain beneficial results. (c) The effect of Mn is not due to reduced Fe absorption by the plant. (d) There is some relation between Mn and chlorophyll formation, and hence with C assimilation in plants. (e) Ca definitely counteracts the toxicity of high Mn concns. L. W. RIGGS

Mannan of iris seeds. H. COLIN AND A. AUGEM. *Bull. soc. chim. biol.* 10, 822-5 (1928); cf. C. A. 21, 3930; 22, 2393.—The horny material which constitutes the sugar reserve of the albumin of iris seeds is a manno-araban which yields on hydrolysis 18% arabinose and 82% mannose. This mannoaraban appears to be the same in each of the species *Iris pseudacorus*, *I. germanica* and *I. foetidissima*. L. W. RIGGS

Electrocapillary penetration of coloring materials in the cell. W. KOPACZEWSKI. *Compt. rend.* 186, 1758-61(1928).—The cells of living white flowers allow only the acid dyes to penetrate them. This penetration increases as the dispersion of the dye is greater. Only basic dyes penetrated the paramecium and this penetration did not depend on the degree of dispersion of the dye.

L. W. RIGGS

Transformation of starch granules into crystals of calcium oxalate in plant cells under the action of ultra-violet rays. G. NADSON AND F. ROCHLINE-GLEICHGEWICHT. *Compt. rend. soc. biol.* 99, 131-3(1928); cf. *C. A.* 22, 1792.—The transformation as seen under magnifications of 1000 to 1500 diams. is described and illustrated. Ultra-violet rays have a power to increase the oxidation in the cells, transforming starch to oxalic acid, with the probability of sugar as an intermediate stage. In general cells contg. a max. of CaC_2O_4 contain a min. of starch granules.

L. W. RIGGS

Staining reactions of fern gametes. J. R. JACKSON AND H. W. RICKETTS. *Science* 68, 89-90(1928); cf. Naylor, *C. A.* 21, 944.—Methods similar to those of Naylor were applied to fern antherozoids (microgametes). The prothallia of *Pteris longifolia* were grown in culture. Antherozoids were obtained by mounting prothallia in a drop of water on a slide. They were fixed by inverting the slide over 1% osmic acid for 30 sec. After drying the slides were immersed in 1% aq. solns. of stains and afterwards washed in buffer solns. composed of *M*/200 potassium acid phthalate and NaOH. The buffer solns. varied in p_H by intervals of 0.2 or 0.3 from p_H 4.1 to 6.0. The amt. of Na was held const. by the addn. of NaCl. The nucleus of the antherozoid retained the acid dyes and lost the basic dyes in buffer solns. acid to about p_H 4.5, but retained the basic dyes and lost the acid in more alk. solns. The isoelec. point of the nucleus by this method is, therefore, about 4.5. The isoelec. point of the cytoplasm in the same slides is near 5.0. Details of differential staining are given.

L. W. RIGGS

The extraction and separation of chlorophyll (a + b), carotin and xanthophyll in fresh green leaves, preliminary to their determination. F. M. SCHERTZ. *Plant Physiology* 3, 211-6(1928).—A method is described for quantitatively extg., sepg. and detg. chlorophyll (a + b), carotin and xanthophyll in fresh green leaves. The method is a modification of the one given by Willstätter and Stoll.

F. M. SCHERTZ

Coccus phyllosepticus and Coccus zymophyllosepticus m. sp. J. GRÜSS. *Wochschr. Brauw.* 45, 232-5, 241-4(1928).—The disease found on the leaves of the white sea rose, *Nymphaea alba*, is caused by the action of the cytase liberated by the above organisms.

A. SCHULTZ

The effect of the salt concentrations of the culture solution on the growth and composition of pineapple plants. C. P. SIDERIS, B. H. KRAUSS AND E. MASUNAGA. *Am. J. Botany* 15, 353-71(1928).—Pineapple plants grown in culture solns. of low concn. contain less salts than when grown in solns. of high concn. A very high salt concn. in the soln. will increase the salt content of the tissue fluid of young leaves 25 to 50% and of old leaves from 50 to 150%. The p_H of the external soln. had no influence on that of the tissue fluids. Plants grown in culture solns. of salt concn. equal to that of the tissue fluid, or higher, grew slowly and when grown in solns. of lower concns. than the tissue fluid grew very rapidly. A salt soln. of medium concn. developed the best plants. Salt content of older tissues of the same organ is higher than that of the younger tissues. Young leaves contain a lower salt concn. than older leaves. The acidity of the tissue fluid from different parts of the same organ varied considerably. The portion of the tissue fluid from different parts of the same organ varied considerably. The portion of the tissue lying between the white and green tissue of the leaf has the highest degree of acidity.

J. J. SKINNER

The importance of temperature in the use of chemicals for hastening the sprouting of dormant potato tubers. F. E. DENNY. *Am. J. Botany* 15, 395-404(1928); cf. *C. A.* 21, 1137.—When the germination of dormant potato tubers was hastened by dipping the cut tubers into a dil. soln. of ethylene chlorohydrin and storing in closed containers for 24 hrs., the temp. which prevailed during the 24-hr. storage period was found to be an important factor. Favorable results were obtained by adding 30 cc. of 40% ethylene chlorohydrin to 970 cc. H_2O at 20°, 25° and 30°, but at 35° the seed pieces were killed. The soln. was only partially effective at a temp. below 20° and many pieces remained dormant. When NaCNS was used the temp. of the soln. was of less importance. Good results were obtained at 15°, 22° and 30°. Toxicity was observed at 35°.

J. J. SKINNER

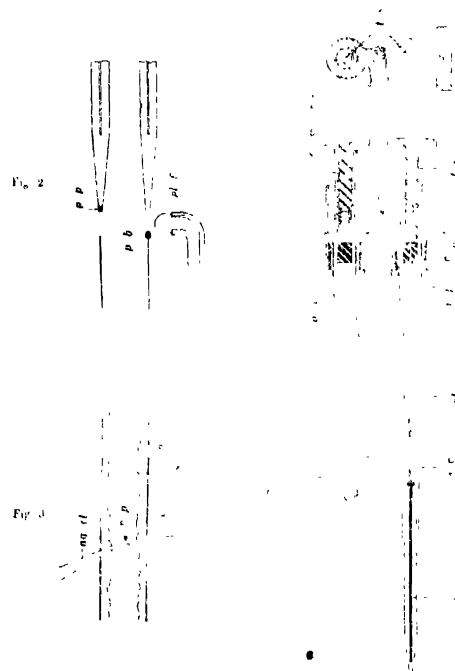

Catalase in relation to growth and other changes in plant tissue. J. F. KNOTT. *New York Agr. Expt. Sta. (Ithaca), Mem.* 106, 63 pp.(1927).—Young and old leaves of spinach and celery are usually lower in catalase activity than leaves of intermediate age. An increase of 10° in temp. increased the catalase activity of celery plants in 24

hrs. and when removed to a 10° lower temp the higher catalase content was maintained several days. No relation was found between the p_H of the juice of the plant as a whole or of the apical 2 in. of the seed stalk and the catalase activity of the intermediate leaves. No significant difference in catalase in the leaves of plants could be observed in respect to a vegetative or a reproductive type of growth. Respiration as measured by CO_2 evolution seemed to be higher in the apical tissues from vegetative plants. Fertilizing with P and N resulted in increased catalase activity. $Ca(NO_3)_2$, when added to catalase in bottles, decreased, while asparagine, sucrose and sol starch increased the activity after 24 hrs. when added in amts. which increased by 50 to 100% the N, amino acid, sugar and starch content of the tissue.

J. J. SKINNER

Potentiometric determinations in the protoplasm and cell sap of *Nitella*. C. V. TAYLOR AND D. M. WHITAKER. *Protoplasma* 3, 1-6(1927).—A non-polarizable micro-

electrode was constructed and used as a H electrode for the potentiometric measurement of the protoplasm and cell sap of *Nitella*. The protoplasm and cell sap behaved very differently toward the electrode. The protoplasm at once produced a potential of between +0.093 and +0.030 v. The values are interpreted as indicating the oxidation-reduction potential. Readings for the cell sap gave p_H values of 5.47 to 6.16. Explanation of Plate: Fig. 1.—Microelectrode enclosed within its quartz sheath which is terminal part of the micropipet apparatus, *el*, microelectrode; *i. c.*, inner cap; *o. c.*, outer cap; *p. w.*, Pt wire; *r. p.*, rubber plug enclosing small brass tube which supports quartz capillary on which is cemented electrode; *s. c.*, stopcock; *sh.*, shank of micropipet which is filled with Hg; *t. s.*, thumb-screw. Fig. 2.—Two views of micropipet tip, showing how it is sealed with paraffin plug; *p. b.*, paraffin ball on tip of quartz needle; *pl. f.*, Pt filament heated electrically for melting paraffin ball whereupon tip of pipet is brought in contact with the melting paraffin; *p. p.*, paraffin plug, formerly paraffin ball,

in tip of pipet. Fig. 3.—Diagram of portion of cell of *Nitella* showing H electrode and agar KCl electrode in cell sap, *ag. el*, agar-KCl electrode; *c. s.*, cell sap; *c. w.*, cell wall; *p. p.*, paraffin plug having been pushed out by tip of H electrode; *pr.*, streaming protoplasm, granular in contrast to the clear cell-sap.

M. H. SOULE

The permeability and the thickness of the plasma membrane as determined by electric currents of high and low frequency. J. F. MCLENDON. *Protoplasma* 3, 71-81(1927).—A review particularly of the change in resistance assocd. with life and activity.

M. H. SOULE

Temperature and other factors affecting the rest period of potato tubers. W. E. LOOMIS. Univ. of Arkansas. *Plant Physiology* 2, 287-302(1927); cf. *C. A.* 6, 241; 10, 1878; 21, 1137.—Extensive studies of the sep. and combined effects of humidity and temp. and also of nitrogenous fertilizers on breaking the rest period of Irish potatoes are described. Dormancy was broken in 4 weeks by storage during July in the attic of a low-roofed building. The optimum storage temp. varied with the size and the condition of the tubers and the duration of the expt. Temps. of 30-33° were found very satisfactory. Composted soils and low concns. of nitrogenous fertilizers had a stimulating effect. Dormancy is probably related to a greater degree to cytoplasmic structure than to chem. compn. or enzyme formation and the rest period may be broken by some such change as the reversal of the lipid, proteinaceous phases in the cyto-

plasm whereby the permeability of the cell is increased and the enzymes assocd. with the protein phase are liberated.

WALTER THOMAS

The basic nitrogen of plant extracts. HUBERT B. VICKERY. Agr. Expt. Sta., New Haven, Connecticut. *Plant Physiology* 2, 303-11(1927).—A discussion of the problem of the pptg. reagent most suitable for the investigation of the bases that occur in plant exts. Although phosphotungstic acid is fairly definite in its action on the mixt. of amino acids obtained from the hydrolysis of proteins, it is an uncertain measure of the true basic N of plants. Illustrations from V.'s investigations on yeast and alfalfa exts. (*C. A.* 18, 3407; 19, 3513, 20, 2806) are given to show that, in addn. to basic substances, phosphotungstic acid ppts. not only compds. of polypeptide nature which yield simple monoamino acids on hydrolysis but also nitrogenous substances that are not bases. This reagent is, therefore, far less selective than was formerly supposed. There is need for much further work before the different basic fractions can be sepd. from one another with certainty. The lysine fractions obtained by the usual procedure contained much N in forms other than lysine: probably a mixt. of polypeptides. Conclusion: The total N pptd. by phosphotungstic acid should be accepted as a measure of the basic N of plant exts. only when this ppt. has been produced in a relatively simple mixt. In general, pptn. with this reagent must be regarded as only a preliminary step. W. T.

Electrodialysis as a means of studying biochemical differences in abnormal apple tissue. JAMES C. MOORE, R. G. REEVES AND R. M. HIXON. Iowa State Coll., Ames. *Plant Physiology* 2, 313-24(1927).—Weighed quantities of the peelings from both diseased-free and spotted Jonathan apples were subjected to electrodialysis, a modified Mattson cell (*C. A.* 20, 3766) being used. After titration the dialyzates were evapd. to dryness and ashed. The data obtained confirmed Pentzer's theory (*C. A.* 20, 2185) that Jonathan spot was caused by a loss of acids during storage. K and Na are removed from the tissue in the first hr. of the dialyzing process, but Ca, Mg, Fe and Al are not removed until the lapse of 130 min. Conclusion: Electrodialysis offers a convenient means of studying chem. differences in the non-colloidal constituents of normal and abnormal tissue. Quant. differences which would be masked by large quantities of inert material are accentuated by this method of sepg. those portions which are sol. and chemically active.

WALTER THOMAS

Germination and growth of seeds as dependent upon selective irradiation. GEORGE M. HIGGINS AND CHARLES SHEARD. Mayo Clinic and the Mayo Foundation, Rochester, Minnesota. *Plant Physiology* 2, 325-35(1927); cf. *C. A.* 21, 3236.—The germination and growth of cucumber seeds were observed under filters of a known transmission, exposed to ultra-violet radiation for given periods of time. Selective irradiation modified the time of germination of the seeds and the rate of subsequent growth. Wave lengths of 320m μ to 390m μ in the "near" ultra-violet region (transmitted by Corning ultra-glass, 586 ÅW) were particularly effective in inducing growth; but wave lengths of 270m μ to 320m μ were inhibitory in their action, and also delay the time and reduce the rate of growth, due to coagulation of the seed albumin. Some of the energy emitted by the lamp and absorbed by the seed may be rendered ineffective by subsequent exposure of the seed to the visible and near infra-red regions of interior daylight. Certain wave lengths of radiant energy are more potent in germination than temp. With a const. temp., germination and growth in the dark greatly exceed those in daylight as transmitted by ordinary window-glass. A certain amt. of energy produced under the action of lesser wave lengths of sunlight is normally stored up within the seeds, and under proper conditions of light and moisture this energy induces germination. Lesser wave lengths of light act as stimulative agents which modify the control of endogenous processes and accelerate germination, while subsequent growth and development of the plant is a function of the visible or infra-red wave lengths. The article is illustrated with spectrograms.

WALTER THOMAS

The so-called balanophorin (ULTRÆ) 10.

E—NUTRITION

PHILIP B. HAWK

Rickets in rats. IV. The effect of varying the acid-base content of the diet. A. T. SHOHL, H. B. BENNETT AND K. L. WEED. Yale Univ. *J. Biol. Chem.* 78, 181-90(1928); cf. *C. A.* 21, 3387.—The same amt. of phosphate added to high-Ca, low-P, rickets-producing diets so that the resulting mixts. were alk., acid or neutral, resp., induced a cure of rickets in rats as manifested histologically. The blood serum under these conditions showed the characteristics of tetany with alk. diets, and of rickets with acid diets. The clinical picture showed the characteristics of tetany, occasionally in

the alk., always in the neutral and never in the acid diets. Greatest ash deposition in the bones occurred with the neutral diet; least with the acid diet. The largest retentions of Ca and P as shown by metabolic studies occurred when the neutral diet was used.

The effect of a tryptophan-poor diet. E. SCHILL. *Wiener Arch. inn. Med.* **15**, 547-60(1928).—On the theory that tryptophan is the basic substance of thyroxin, a diet high in calories but poor in tryptophan was tried in 22 cases of Basedow's disease. Such a diet may contain corn-meal and rye flour with but little wheat, no meat, but gelatin, potatoes, green vegetables, fruit, fats and carbohydrates. In 18 of the 22 cases such a tryptophan-poor diet continued for some months was followed by a lowered basic metabolism and an improvement in subjective symptoms which continued after return to a diet containing more protein. Animal expts indicate that a tryptophan-poor diet is preferable to a tryptophan-free diet.

The effects of protein-split products upon metabolism, and their relation to the specific dynamic action of proteins. DAVID RAPPORT AND H. II. BEARD. *Proc. Am. Physiol. Soc., Am. J. Physiol.* **81**, 505(1927).—In protein hydrolysis mixts. the fraction extd. by and pptd. in BuOH (monoaminomonocarboxylic acids) contained amino acids having high specific dynamic action. Phenylalanine and leucine were found to account for most of the stimulating effect in the ext. from hydrolyzed casein. The specific dynamic action of casein and gelatin cannot be explained wholly on the basis of constituent amino acids known to have such action.

Physiological investigation on baking powders. GEORGES SCHAEFFER, GEORGES FONTÈS, ELIANE LE BRETON, CHARLES OBERLING AND LUCIEN THIVOILLE. *Bull. soc. hyg. aliment.* **16**, 1-24, 49-79(1928).—Very extensive chem. and physiol. investigations, which are described in detail, lead to the following conclusions: (1) After baking, bread which has been raised with "alum phosphate baking powder" contains $AlPO_4$, which is not inert as it passes through the digestive tract. (2) $AlPO_4$ is dissolved by the HCl of gastric juice, both *in vitro* and *in vivo*. (3) The resultant $AlCl_3$ is not reprecipitated in the duodenum by the alk. pancreatic juice when the chyme is neutralized; bile prevents this reaction to a certain extent, in a manner as yet undetd. (4) Resorption of Al is shown by the fact that Al is found in detectable amts. in certain organs after prolonged ingestion of baking powders with Al base; microchem. detn. of Fe in the spleen shows a decrease in the Fe reserve of that organ, suggesting a displacement by Al. (5) Ingestion of bread contg. $AlPO_4$ (residues from reaction of alum phosphate baking powder during baking) causes a distinct retardation of gastric evacuation in dogs. Prolonged use of such bread does not cause any lesions of the gastric mucous membranes in that animal; but it produces diarrhea, particularly towards the beginning which disappears more or less when the system becomes accustomed to the Al. It causes clearly characterized irritative lesions of the mucous membrane of the large intestine; it does not affect the max. elimination of uric acid, showing it has no action on the kidneys. (6) Diets contg. $AlPO_4$ or alum phosphate baking powder are not immediately toxic to rats, excepting those weighing less than 90 g.; and above that wt. the growth remains normal with a suitable diet. (7) With chickens, such a diet affects only chicks less than 4 weeks old, provided the diet contains a considerable proportion of inorg. salts, as otherwise Al distinctly retards growth. (8) Alum and alum phosphate bread interfere neither with the equil. nor with the growth of mice. Anatomopathological examn. of the digestive tract shows ulcerous lesions of the pyloric and gastric mucous membranes after prolonged use of such bread. The intestine is unaffected. If an excess of Osborne and Mendel's synthetic salt mixt. is added to the diet, only ordinary gastritis lesions are observed, which is probably due to the added salts modifying the usual reaction between $AlPO_4$ and the HCl of gastric juice and preventing the formation of $AlCl_3$ by reaction of the HCl with the other cations. Under the ordinary conditions of the use of alum baking powders by man, production of $AlCl_3$ in the stomach takes place, and it can cause ulcers of the stomach and duodenum which are so prevalent in countries where such baking powders are habitually used. (9) Osborne and Mendel's salt mixt., even in the absence of alum or its reaction products, causes chronic gastritis when present in the diet in amts. treble the max. recommended by Osborne and Mendel (5%). (10) The most characteristic effect of diets contg. Al is a selective action on the female genital gland, which can be noticed at the end of 4 months, consisting of an approx. 50% atrophy of the ovaries with considerable follicular atresia. These lesions result in a reduction of the fertility of females, which is quite apparent after 4 months of the above-mentioned diet. Since control animals never exhibited this trouble, it is considered specific. In males which were fed on the same diet no disturbance was noted in the testicles, which always showed active spermatogenesis.

A. PAPINEAU-COUTURE

Deficiency and magnesium. PIERRE DELBET AND PALIOS. *Compt. rend. soc. biol.* 99, 390-2(1928); cf. *C. A.* 22, 3459.—Feeding expts. with guinea pigs indicated that $MgCl_2$ permits or regulates certain syntheses which are prevented or disturbed in the absence of antiscorbutic vitamins. L. W. ROGGS

The vitamin A content of cod-liver oils. J. C. DRUMMOND. *Lancet* 1928, I, 1353-4.—This is an answer to a criticism by E. Poulsen (*C. A.* 20, 3489). The former opinion, that, in general, Newfoundland oils possess a higher vitamin A potency than those from the chief center of the Norwegian industry, is still held and data are promised shortly to strengthen this statement. A discussion of the relative values of the colorimetric and biol. methods is given. F. B. SEIBERT

CENTANNI, EUGENIO. *Le ultime vedute sulla reintegrazione degli alimenti.* Milan: 1st. ed. Cisalpino. 46 pp. L. 10.

F—PHYSIOLOGY

E. K. MARSHALL, JR.

Relation between glutathione and the intracellular oxidation-reduction potential. P. JOYET-LAVERGNE. *Compt. rend. soc. biol.* 97, 140-2(1927).—Glutathione is an important factor in the r_H value and therefore influences the intracellular respiration. In organs the regions rich in glutathione appear to be those of the most intensive carbohydrate metabolism. B. C. A.

The problem of bilirubin. KIRKOVIC AND RUSSEV. *Vox medica* 7, 157-9; *Chem. Zentr.* 1927, II, 115.—The liver is not the place of origin of blood bilirubin. The latter is formed in the large blood vessels and in the heart and is in part retained by the capillaries. Though the mode of formation of bilirubin in the heart and in the blood vessels is not clear, it may be assumed to have its origin in the circulating blood or in the cardiovascular endothelium. There is no evidence that the liver bilirubin is formed at the expense of blood bilirubin, or that the liver bilirubin exists preformed in the liver. It can be assumed merely that blood bilirubin is of extrahepatic origin, and that biliary bilirubin is formed in the liver. The following proportions of bilirubin were found: ear lobe, 1:310,000; finger point, 1:240,000 to 1:280,000; cubital vein, 1:200,000 to 1:230,000. C. C. DAVIS

The alkaline tide in urine. JEAN M. D. SMALL. Univ. of Glasgow. *Glasgow Med. J.* [NS] 29, 33-9(1928).—Expts were made in which the urine was collected hourly for 2-6 hrs. after different breakfasts. The max. alk. tide was noted the 3rd and 4th hr. after the breakfast while no changes in urine acidity were found when tea alone was taken. The greatest response was noted when haddock or bananas were taken with roll and tea. It could not be proved whether it was related to gastric secretion. H. J. DEUEL, JR.

The iron content of blood serum. Comments on the paper of E. Abderhalden and P. Möller. GEORG BARKAN. *Z. physiol. Chem.* 177, 105-7(1928); cf. *C. A.* 22, 3201. Reply to the preceding comments of Georg Barkan. EMIL ABDERHALDEN. *Ibid* 207-10.—Polemical, regarding the non-hemoglobin Fe of blood serum. A. W. D.

Oxidizing substances in animal cells. W. LOELE. *Arch. path. Anat.* (Virchow's) 261, 484-502(1926). H. G.

New research on assimilation. MARIA KOBEL. *Naturwissenschaften* 16, 457-60 (1928).—A review with 21 references. B. J. C. VAN DER HOEVEN

Potassium content of the blood in the menstrual cycle. R. SPIEGLER. *Arch. Gynäkol.* 134, 322-7(1928).—The av. of 36 cases indicates that the K content of the blood is increased in the premenstrual period, is decreased during the menstrual period and slowly regains the normal value in the postmenstrual period. H. F. H.

The distribution and amount of calcium and potassium in normal tissue of the mouse. A histochemical study. G. L. ROHDENBURG AND J. GEIGER. *Arch. Path. Lab. Med.* 6, 215-27(1928).—K is found in largest amounts in tissues in which physiologic activity is marked, as pancreas, salivary glands, liver. It is also found in areas in which cell replacement is continually going on, as the layer germinativa. Ca is found in greatest amounts where reparative processes are most often associated with calcification, as lung, lymph glands. Peculiar concns. of K and Ca have been found in the nervous system and other places which for the present cannot be connected with the functions of the tissues involved. K is found in the female ovum while Ca is found in the male spermatozoa. K and Ca are segregated in the peripheral zone of the suprarenal gland and are possibly correlated with the dense K deposit in the thymus. H. F. H.

The concentration index of bile salts in the duodenal juice. L. DÉRER. *Wiener Arch. klin. Med.* 15, 303-8(1928).—The concn. index of bile salts in the duodenal juice

is expressed by the formula $J = a \cdot b/b_1 \cdot a_1$, in which a and a_1 are the mg.% of bilirubin in bile "A" and "B" and b and b_1 the mg.% of cholates in the same fraction. Bile "A" represents the bile obtained with the duodenal sound after 10-20 cc. of choledochus bile has been rejected and Bile "B" the bile obtained after instillation of MgSO_4 and produced by emptying of the gall bladder. The concn. index expresses the change in relation between bilirubin and bile salts during the storage of bile in the gall bladder.

HARRIET F. HOLMES

The influence of physical training on the basal respiratory exchange, pulse rate and arterial blood pressure. EDWARD C. SCHNEIDER, ROBERT W. CLARKE AND GORDON C. RING. Wesleyan Univ. *Am. J. Physiol.* **81**, 255-63(1927).—Physical training was accompanied by a decline in basal metabolism in three subjects and was unchanged in two others. Training slowed the basal and early morning standing posture pulse rates, but did not affect the early morning arterial pressure. J. F. LYMAN

Basal metabolism in the rat during the estrous cycle. MILTON O. LEE. Proc. Am. Physiol. Soc., *Am. J. Physiol.* **81**, 492(1927).—An increase in heat production of about 12% was observed during the last 10 hrs. of the diestrus and beginning of proestrus. There was no increase during estrus (stage II). After removal of the ovaries heat production fell about 10% from the original level. J. F. LYMAN

The respiration and lactic acid metabolism of excised testicular tissue. ROBERT O. LOEBEL AND R. A. HICKLING. Proc. Am. Physiol. Soc., *Am. J. Physiol.* **81**, 494(1927).—Testicular tissues from the rat showed a low and falling O_2 consumption in the absence of foodstuff. In the presence of sodium lactate, O_2 was used in larger and constant amts., while lactate disappeared and the respiratory quotient rose. J. F. L.

The specific dynamic action of glycocoll and alanine with special reference to the dehepatised animal. FRANK C. MANN, CHARLES M. WILHELMJ AND JEAN L. BOLLMAN. Proc. Am. Physiol. Soc., *Am. J. Physiol.* **81**, 496(1927).—The authors were not able to obtain a specific dynamic action toward amino acids in an animal whose liver has been removed. J. F. LYMAN

The excess metabolism and muscular efficiency for moderate work. M. FLIZABETH MARSH. Proc. Am. Physiol. Soc., *Am. J. Physiol.* **81**, 497(1927).—The respiratory quotient of the excess metabolism during work varied from 0.78 to 1.00. The net efficiency of a subject on a fat diet was less than on a carbohydrate diet but the difference at the end of 3 days was only slight and reached 11% at the end of 11 days. J. F. LYMAN

Factors influencing the anaerobic activity of cardiac muscle. ALFRED C. REDFIELD AND JOHN T. EDSALL. Proc. Am. Physiol. Soc., *Am. J. Physiol.* **81**, 505-6(1927).—Turtle's cardiac muscle contracting isometrically in the absence of O_2 fatigued according to the law that each systole diminishes the magnitude of the stress which is developed as the result of the next systole by a const. fraction of itself. J. F. L.

Effects of thymus, muscle and pituitary extracts on normal and thyro-parathyroidectomized dogs. E. LARSON AND N. F. FISHER. Univ. Ill. *Am. J. Physiol.* **84**, 330-7(1928).—Exts. of calf thymus and muscle prepd. by the same methods used for prepg. potent parathyroid exts. had a slight ameliorating action on acute parathyroid tetany, but did not cause sufficient changes in the Ca of the blood to account for their action. No parathyroid-like principle in the exts. could be demonstrated. J. F. LYMAN

The simultaneous study of the constituents of the sweat, urine and blood, also gastric acidity and other manifestations resulting from sweating. V. Gastric acidity. G. A. TALBERT AND I. ROSENBERG. Univ. N. Dakota. *Am. J. Physiol.* **84**, 520-3(1928).—During heat sweating there was a more or less sudden decline in gastric acidity. VI. Sugar. S. SILVERS, W. FORSTER AND G. A. TALBERT. *Ibid* 577-82.—Sweat contained sugar, 2.8 to 40 mg. per 100 cc. Sweating tended to increase the blood-sugar concn. J. F. LYMAN

The effect of low glycogen content on the fatigue curve and on lactic acid formation in excised muscle. J. M. D. OLMSTED AND H. S. COULTHARD. Univ. Toronto. *Am. J. Physiol.* **84**, 610-7(1928).—Normal isolated muscles when subjected to elec. stimulation or to CHCl_3 rigor showed a loss of glycogen which was exactly balanced by a gain in lactic acid. Frogs suffering from insulin convulsions were found to have very little or no muscle glycogen. When such muscles were fatigued they showed very trifling loss of glycogen or gain in lactic acid, the increase of the latter being greater than the loss of the former. Free carbohydrates and phosphate compds. in muscle cannot account for the excess of lactic acid gained over glycogen lost in muscles from insulin-treated frogs. J. F. LYMAN

Tissue respiration and endocrine functions. I. The influence of thyroidectomy on the indophenol oxidase content of animal tissues. J. A. DYER AND R. A. WAG-

GENER. Cornell Univ. *Am. J. Physiol.* 85, 1-13(1928).—Without exception, tissues of thyroidectomized animals (pups and lambs) showed a marked diminution in indophenol oxidase. In lambs this reduction varied from 24% for the heart to 50% for skeletal muscle. Lower values were obtained for the pups in which all tissues seemed to be affected to about the same extent. II. The indophenol oxidase content of animal tissues after total thyroparathyroidectomy in dogs. J. A. DYE AND R. A. WAGGENER. *Ibid* 14-20.—After thyroparathyroidectomy an increase in oxidation power was noted in all the tissues except kidney. J. F. LYMAN

The nature of the foodstuffs oxidized to provide energy in muscular exercise. II. In the phlorhizinized animal. DAVID RAPPORT AND ELAINE P. RALLI. Western Reserve Univ. *Am. J. Physiol.* 85, 21-32(1928); cf. *C. A.* 22, 3437.—Phlorhizinized dogs made to work on a treadmill showed a diminution in the oxidation of glucose, even though a hyperglucemia existed. The fuel requirements both during rest and exercise were provided by the oxidation of fat to a greater extent than in the normal animal. J. F. LYMAN

The inorganic constituents of the body with respect to their stimulating effect on sugar metabolism. W. F. BURGE AND A. M. ESTES. Univ. Ill. *Am. J. Physiol.* 85, 103-5(1928).—Goldfish were placed in 0.1% glucose solns. to which various salts were also added. After 30 hrs. the loss in sugar was detd., a sugar soln. without addition of salts being used as control. K_2HPO_4 produced a marked acceleration of the rate at which sugar disappeared; Na_2HPO_4 increased the rate somewhat; while $MgSO_4$ retarded it. Other salts were without effect. Similar results were obtained with *Paramecium caudatum*. J. F. LYMAN

Cutaneous respiration of the cat. LOUIS A. SHAW. Harvard. *Am. J. Physiol.* 85, 158-67(1928).—The cutaneous respiration of the cat was about 65-74% of the pulmonary respiration, and is the result of metabolic changes in the epidermis, the deeper layers of skin not being involved. The skin is thought to be freely permeable to the inward diffusion of CO_2 and the outward diffusion of O_2 but impermeable to CO_2 and O_2 when passing in the reverse directions. J. F. LYMAN

The digestion and absorption of fat. J. MELLANBY. Proc. Physiol. Soc., *J. Physiol.* 64, 1(1927).—A mixt. of neutral fat and bile, to which no lipase has access, was rapidly absorbed from the duodenum or jejunum into the lymphatics; therefore hydrolysis of fats need not precede their absorption from the intestine. J. F. L.

The influence of acid-base equilibrium on the activities of blood vessels. R. J. S. McDOWALL. Univ. London. *J. Physiol.* 65, 25-32(1928).—Dil. acids and also dil. alkalis either constricted or dilated the blood vessels through which they were perfused according to the conditions which prevailed at the time. J. F. LYMAN

Factors influencing the concentration of hydrochloric acid during gastric digestion. HUGH MACLEAN AND WILLIAM J. GRIFFITHS. St. Thomas's Hospital. *J. Physiol.* 65, 63-76(1928).—The changes in HCl and neutral chlorides in the stomach contents of man after the ingestion of a test meal or of solns. of Na_2SO_4 or H_2SO_4 support the conclusion that: (1) The fall in HCl and corresponding rise in NaCl in the stomach contents during digestion are not brought about by regurgitation of alk. fluid from the duodenum. (2) The normal stomach secretes the Cl ion in about the concn. in which it is present in the blood. Some of the Cl is secreted as HCl and some as NaCl, the proportion of the 2 forms being different at different stages of digestion. J. F. L.

Variations in the acidity and total chloride contained in the secretion from an isolated Pavlov pouch in the dog. HUGH MACLEAN, WILLIAM J. GRIFFITHS AND B. W. WILLIAMS. St. Thomas's Hospital. *J. Physiol.* 65, 77-82(1928); cf. preceding abstr.—The secretion obtained from an isolated Pavlov pouch of the dog stomach during digestion showed a rise in acid concn., followed by a definite fall, the total chloride remaining const. J. F. LYMAN

Oxygen usage by the kidney. A. R. FEE AND A. HEMINGWAY. Univ. Coll., London. *J. Physiol.* 65, 100-8(1928).— O_2 consumption in the isolated perfused kidney varied between 0.03 and 0.20 cc. per g. of kidney per min. As the vol. of urine gradually rose there was a corresponding rise in O_2 consumption. Increased arterial pressure caused a rise in O_2 consumption, while the addition of small amts. of pituitary ext. to the perfusing fluid produced a diminished vol. and an increased chloride concn. of the urine associated with a fall in O_2 used by the kidney. J. F. LYMAN

Tissue oxygen tension and hemoglobin. J. ARGYLL CAMPBELL. Nat. Inst. Med. Research, Hampstead. *J. Physiol.* 65, 255-72(1928); cf. *C. A.* 21, 1670.—When the hemoglobin in rabbits was markedly lowered by bleeding or by injections of hemolytic serum a decided lowering in tissue O_2 tension was observed; when hemoglobin was raised,

by injection of blood and by exposure to low O_2 pressure in the air, an increase in tissue O_2 tension occurred. J. F. LYMAN

Physiology of the liver and intestine. Method of study. CYRUS F. HORINE. Univ. of Maryland. *Arch. Surg.* 17, 289-95(1928).—A permanent cannula is used between the portal vein and the skin of the abdominal wall. It is sterling silver gold-plated and consists of 2 tubes which barely allow the passage of an 18-gage record needle. The tubes connect with a concave portion which is sutured to the portal vein and to a round flat plate about the size of a silver dollar, which is placed beneath the skin of the abdominal wall. JOHN T. MYERS

The effect of the administration of iodized substances on the feathers of chickens compared with that of thyroid. E. GIACOMINI. *Boll. soc. ital. biol. sper.* 3, 326-31 (1928).—Iodized egg-yolk fed to a capon produced the same results as thyroid feeding, i. e., the loss of feathers. Iodized proteins are capable of producing an action similar to thyroid not only on tad poles and axolotl but also on warm-blooded animals. PETER MASUCCI

Low blood pressure and secretory activity. WILLIAM ALEXANDER OSBORNE. *Australian J. Exptl. Biol. Med. Sci.* 5, 171-2(1928).—Low systemic arterial blood pressure produced by trinitrin, by vagal heart stoppage, or by hemorrhage fails to excite the dog pancreas and submaxillary to secretion. The secretion obtained by peptone and histamine can be otherwise explained. The conclusions of Lim and Schlapp and of Margaret MacKay are supported. L. W. RIGGS

Increase in metabolism produced by excitation of the sciatic nerve in the curarized animal. A. OZORIO DE ALMEIDA AND BRANCA DE A. FIALHO. *Compt. rend. soc. biol.* 99, 146-8(1928).—Expts. were made with frogs and toads to det. the O consumption per kg.-hr. in curarized animals with intact sciatic nerves. The increased metabolism in 4 frogs and 6 toads averaged 26.7%. In 4 curarized animals in which the peripheral extremities of the two sciatic nerves were excited the av. increase in O consumption was 14.1%. Apparently this nerve action is exercised directly upon the velocity of the chem. reactions which take place in the tissues. L. W. RIGGS

Excitability of the adrenalino-secretory fibers of the great splanchnic nerve. Frequencies, threshold and optimum of the stimulus. Role of the calcium ion. B. A. HOUSSAY AND E. A. MOLINELLI. *Compt. rend. soc. biol.* 99, 172-4(1928).—The tests were made on chloralosed dogs united in surreno-jugular anastomosis. The presence of the Ca ion appears necessary that the excitation of the great splanchnic nerve may produce its vasomotor and adrenalino-secretory effects. In general the results of this study agree with those of previous studies. L. W. RIGGS

Glycogen in the central nervous system of some mammals. I. The distribution of glycogen in the central nervous system of mammals and a comparison with it of the birds. HYOSAKU TANAKA. *Sei-i-kwai Med. J.* 47, 21-45(1928).—A large quantity of glycogen is found normally in the central nervous systems of birds, albino rats, guinea pigs and rabbits, the quantity for the different animals being in the order named. It occurs in brains and spinal cords and is commonly contained in ganglion cells, appearing in the form of Nissl granules. The glycogen content of glia tissues and epithelia of *Plexus chorioideus* is very small and very variable. In white substance, ependym cells and posterior lobe of *Hypophysis cerebri* glycogen granules were not demonstrated. L. W. RIGGS

Cholesterol and cholesterol ester content of bovine colostrum. RICHARD E. SHOFF AND JOHN W. GOWEN. Rockefeller Inst. *J. Exptl. Med.* 48, 21-4(1928).—The total amt. of cholesterol found in colostrum and milk is comparatively low. The amt. of cholesterol found in colostrum declines at an ever decreasing rate as milk secretion develops until at 48 hrs. the cholesterol is nearly the same as that found in milk 3 or 7 months after parturition. The morning milk differs from the evening milk in that the cholesterol bound as ester is greater in amt. C. J. WEST

Cholesterol and cholesterol ester in the blood serum of cattle late in pregnancy and during the early lactation period. R. F. SHOFF AND J. W. GOWEN. Rockefeller Inst. *J. Exptl. Med.* 48, 25-30(1928).—The total cholesterol and cholesterol ester of bovine blood serum during the "dry" period of late pregnancy is low. Following parturition the total cholesterol and cholesterol ester of bovine blood serum show a still greater, very transient decrease followed by a gradual rise to reach a rather const. level 40 to 50 days postpartum. This lactation level is very much higher than the "dry" level. C. J. WEST

Influence of light environment on the growth and nutrition of normal rabbits with especial reference to the action of neon light. WADE H. BROWN and MARION HOWARD. Rockefeller Inst. *J. Exptl. Med.* 48, 31-55(1928).—Growth and nutri-

tion were greatly affected by the light environment in which the animals lived. The effects produced by a given environment varied with the color and breed of the animal and appeared to be out of proportion to the differences in the intensity of the light or the energy represented.

C. J. WEST

Blood cell metabolism. I. Effect of methylene blue and other dyes upon the oxygen consumption of mammalian and avian erythrocytes. GEO. A. HARROP AND E. S. GUZMAN BARRON. Johns Hopkins Univ. *J. Exptl. Med.* 48, 207-23(1928).—The respiratory metabolism of non-nucleated mammalian erythrocytes is enormously accelerated and approaches the magnitude of the metabolism of the nucleated erythrocytes of birds on the addn. of methylene blue (I) and certain other dyes, to a final concn. of 0.005-0.0005%. In the presence of I the respiration is accelerated, even when 0.001M KCN is also present. The accelerated respiration due to I occurs at room temp. but it is most active at 38°. I in the above concn. accelerates the respiration of avian (goose) erythrocytes to a much smaller extent than it does the respiration of erythrocytes of mammalian blood, while the effect upon anemic blood seems to be less than it is upon cells of normal goose blood. Because of a rather large initial CO₂ formation in defibrinated blood on incubation, which may not be related to the immediate respiratory process, proper respiratory quotients cannot be obtained in whole blood. When the cells are sepd. from the serum and suspended in Locke's soln., respiratory quotients are obtained upon incubation comparable to those of other resting mammalian cells, as well as of the actively respiring erythrocytes of birds. The hypothesis is advanced that I acts in the role of an O carrier, supplying a substance which has disappeared from adult mammalian non-nucleated erythrocytes and restoring their metabolic activity to an extent comparable to that of the young immature forms, or to that of actively respiring avian blood.

G—PATHOLOGY

H. GIDEON WELLS

The reaction of colloidal gold in indicating endocrine function. BICK NEPPI. *Atti congresso naz. chim. pura applicata* 2, 919-22(1926).—N. has tested the application of colloidal gold to tissue exts. as a means of detg. hormone activity. In each case 1 g. of tissue was ground with 3 g. of MgSO₄ and then a few cc. of physiol. salt soln. added. Four cc. of 4% CCl₃CO₂H was added and the suspension filtered. Both red and blue colloidal Au solns. were used. Reaction with thyroid, testicle, hypophysis (posterior lobe), heart and pancreas, kidney, skin, muscle, connective tissue and fat was pronounced in the first case, but rapidly decreased in intensity, resp., and was entirely absent in the last case.

L. T. FAIRHALL

A confirmation of Kopaczewski's theory of anti-anaphylaxis. GIUSEPPE CAPPELLI. *Atti congresso naz. chim. pura applicata* 2, 1087-91(1926).—The anti-tuberculosis therapy following the method of Capelli-Memmo of injection of colloidal lipase-peroxidase solns. is complicated in about 1% of cases by anaphylactic reaction. Besredka's method of injection alone is insufficient to overcome this. If the lipase-peroxidase soln. is made anti-anaphylactic however according to Kopaczewski's method anaphylaxis is prevented.

L. T. FAIRHALL

The precipitin test for blood. HERBERT S. SIREWSBURY. *Analyst* 53, 380(1928).—Anti-human serum made from fowl is no weaker than serum made from rabbits or guinea pigs. Sera will only remain potent in Trinidad for 3 months, although kept on ice. It is desirable to test the reactions of the blood stain solns. They should be neutral to litmus. Although in applying the antiserum, layering is a good method, sometimes more definite zone reactions are obtained by allowing the antiserum to flow gently down the side of the test tube which is inclined at 45°.

W. T. H.

Tuberculosis allergy and reticulo-endothelial system. W. PAGEL. *Klin. Wochschr.* 7, 700(1928).—Tuberculous guinea pigs, whose reticulo-endothelial cells had been blocked with india ink, react to tuberculin exactly as do the untreated controls. Removal of the spleen is also without effect. This indicates that the tuberculin reaction is not an anaphylactic shock.

MILTON HANKE

Intensifying effect of muscular work upon the action of insulin in normal and in diabetic individuals. M. BÜRGER AND H. KRAMER. *Klin. Wochschr.* 7, 745-50(1928).—Muscular work leads to a protracted hyperglucemia in untreated diabetics. The same amt. of work leads to a hypoglucemia in normal individuals. A given dose of insulin leads to a slight hypoglucemia in a diabetic; but the combination of muscular work plus this same amt. of insulin leads to a marked hypoglucemia. The muscular work increases the intensity of the action of insulin.

MILTON HANKE

Blood sugar in arterial and venous blood. GEORG ROSENOW. *Klin. Wochschr.* 7, 750-2(1928); cf. *C. A.* 21, 3952. MILTON HANKE

The chemistry of the Gaucher substance. HANS BEUMER. *Klin. Wochschr.* 7, 758(1928).—Cerasin and cerbron were present in the alc. ext. from the spleen of a patient afflicted with Gaucher's disease. MILTON HANKE

Sensitization with allergens and the nature of the allergens. L. FARMER LOEB. *Klin. Wochschr.* 7, 803(1928).—The aq. ext. from goose feathers or from pollen contains substances that act as specific allergens. The substances are colloidal and can be pptd. with colloidal $\text{Fe}(\text{OH})_3$ or with alc. MILTON HANKE

The relation of cholesterolemia to disturbances of the estrual cycle. MAX REISS. *Klin. Wochschr.* 7, 849(1928).—A brief report. A detailed report is to appear in the *Endocrinology*. MILTON HANKE

Alcapton in the cerebrospinal fluid of an infant. G. KATSCHE AND A. MADER. *Klin. Wochschr.* 7, 895-6(1928).—The presence of homogentisic acid was demonstrated in the cerebrospinal fluid of an infant afflicted with alcaptonuria. The concn. was approx. 0.1 mg %. The method of Katsch and Metz was employed. M. H.

The metabolism of white blood cells. (Bone marrow cells, blood leucocytes and blood platelets). AKIJI FUJITA. *Klin. Wochschr.* 7, 897-8(1928).—The white cells of the marrow and the blood leucocytes show a basal metabolism (Warburg method) like that of normal embryonic cells and not like that of carcinoma cells. M. H.

The Freund-Kaminer reaction as applied to tissue cultures. ANDREAS KUBÁNYI AND MICHAEL JAKOB. *Klin. Wochschr.* 7, 943-4(1928).—Carcinoma cell cultures die about as rapidly in normal plasma as they do in the plasma from a carcinomatous person. They seem to live just a little longer in a normal isoplasm. MILTON HANKE

Studies on the carcinoma problem. II. The structure of the serum in carcinomatous women. Rapidity of sedimentation of red blood corpuscles, surface tension, viscosity and oncotic pressure. H. GUTHMANN AND H. FRÜHAUF. *Arch. Gynakol.* 134, 425-38(1928).—In women with carcinoma of the genital organs there is a disturbance of the physicochem. conditions of the serum. There is a decrease in surface tension. The erythrocytes show an increased rate of sedimentation though not always in proportion to the severity of the disease. There is a decrease in the oncotic pressure proportional to the extent and severity of the disease and which indicates not only a hydration of the blood but also a disturbance of the entire colloidal system. The viscosity of the serum is increased which is an indication of an increase in size of the protein particles.

HARRIET F. HOLMES

Experimental pigment cirrhosis due to copper poisoning. Its relation to hemochromatosis. E. M. HALL AND E. M. BUTT. *Arch. Path.* 6, 1-25(1928).—Chronic poisoning with Cu salts over long periods produces in rabbits and to a slighter degree in white rats a pigment cirrhosis resembling closely the early manifestations of hemochromatosis in man. Rabbits given Cu acetate in their food or by subcutaneous injection store relatively large quantities of Cu in the liver while only traces of Cu can be found in other organs. Each of two sheep that were given Cu acetate by subcutaneous injection for 26 weeks stored in his liver 54% of the pure Cu administered. Alc. administered in conjunction with Cu acetate not only fails to hasten or augment the production of pigment cirrhosis, but also reduces materially the storage of Cu in the liver of both rabbits and white rats. Hemofuscin is produced in the livers of rabbits treated with Cu. The quantities of this pigment found closely parallels the Cu in any given liver. Hemofuscin contains Fe in masked form. Hemosiderin in small amounts is seen in a few of the livers of the rabbits. It appears to be derived from hemofuscin. Both pigments are no doubt derived from hemoglobin.

HARRIET F. HOLMES

Lipoid cell splenohepatomegaly (Niemann). M. LEDERER. *Arch. Path.* 6, 90-5(1928).—A description is given of a case of lipoid cell splenohepatomegaly in man. In most respects the microscopic changes coincide with those described as occurring in Niemann's splenohepatomegaly. The presence of the characteristic lipoid-bearing cell, the absence of demonstrable Fe, and the most important characteristic, the absence of pathologic cells in the splenic sinuses, distinguish the condition from Gaucher's disease. The great difference from previous experiences as reported is the insolubility of the granules in fat solvents.

HARRIET F. HOLMES

Identification of human seminal stains. Precipitin reaction of seminal fluid. L. HEKTOEN AND G. J. RUKSTINAT. *Arch. Path.* 6, 96-9(1928).—The seminal precipitin reaction reveals the presence in semen of a substance or substances peculiar to it and consequently the reaction may be of value in studying the nature of suspected spots and stains. Landsteiner and Levine (*C. A.* 21, 606) have found that spermatozoa from persons belonging to blood groups A and B absorb specifically the agglutinins for the

red cells of these groups. This fact at once suggests that it may be possible to trace seminal stains to persons of certain blood groups. HARRIET F. HOLMES

Diabetes insipidus. A clinical review and analysis of necropsy reports. E. B. FINK. *Arch. Path.* 6, 102-20(1928).—A general review. HARRIET F. HOLMES

Cancerization of tissue. B. SOKOLOFF. *Neoplasmes* 7, 81-7(1928).—The process of the cancerization of the cell seems to take place in two stages. In the first stage there is a change in the equil. within the tissues brought about by alterations in reaction, in ionic equil. in metabolism of vitamins and cholesterol and in viscosity of the intercellular lipoids. Exogenous factors play an important role at this time. This is the stage of cancerization of the tissue and is followed by the second stage of cancerization of the cells. The cells, freed from the influence of the tissue and with lipid membranes already altered, proceed to the realization of their potential energy. The rhythm and character of cell multiplication alter and the cell no longer is part of a tissue entity but becomes an autonomic unit not obedient to the laws of histogenesis. H. F. H.

The pathogenic role of lymphoid elements in neoplastic processes. B. SOKOLOFF. *Neoplasmes* 7, 88-91(1928).—Studies on lympholytic and hemolytic cancerous sera indicate that the pathogenic principle of neoplasms is comprised not in the malignant cells themselves but in the lymphoid elements, particularly in the macrophages. The macrophages seem to influence cell anarchy by bringing about an alteration in the character of the intercellular lipoids and in the processes of oxidation of the tissue and respiration of the cells. HARRIET F. HOLMES

Oxido-reductions and cancer. P. LEMAY. *Neoplasmes* 7, 92-8(1928).—In cancer there is an acceleration of the synthetic process and in this abnormal growth the part played by the enzymes is great and of these oxidases and reductases are the most important. HARRIET F. HOLMES

The absorption of cholesterol by the tumor. A. H. ROFFO. *Neoplasmes* 7, 147-55(1928).—In human tumors as well as in tumors of the rat and the chicken, there is less cholesterol in the blood which comes directly from the tumor than in the blood supplying the tumor. This indicates a considerable adsorption of cholesterol and is related no doubt to the energetic power of growth of the tumor cells. However, the diminution of cholesterol is not due to a simple adsorption only but there is also a more complicated process connected with tissue disintegration. HARRIET F. HOLMES

Physiology and pathology of peptidase metabolism. H. PFEIFFER. *Wiener Arch. klin. Med.* 15, 209-48(1928).—A study was made of the occurrence of glycytryptophanase in the body and excretions in normal and pathologic conditions. Glycytryptophanase is a constant constituent of all cells. It is found in the albumin fraction of the serum. The peptidase content of the serum varies in different animals and in the guinea pig the ability to split glycytryptophan is about 4 times as great as in man. The quantity of the enzyme in the intestinal contents is large and in man, particularly during youth, is reabsorbed into the circulation from the large intestine and excreted in the urine, while in many animals, as the guinea pig, the body is better protected against the entrance of colloidal material from the intestine. The detn. of the peptidase content gives a measure of the extent of destruction of living tissue and for the permeability of the large intestine permitting the passage of colloidal material into the circulation. It also gives insight into the functional activity of the kidney with regard to the excretion of enzymes. Though peptidase of itself is atoxic its detn. furnishes an indicator of intoxication due to protein decompn. products and as such may be of importance to both pathologists and clinicians. HARRIET F. HOLMES

The value of blood-sugar curves in the test for alimentary galactosuria. R. BAUER AND D. WOZASEK. *Wiener Arch. klin. Med.* 15, 287-302(1928).—In general the detn. of the blood-sugar curve confirms the results obtained by detn. of the sugar content of the urine. The one superiority of the blood-sugar detn. is in the case of ascitic cirrhosis of the liver where the sugar content of the urine is lower than expected. However, as passive congestion due to other causes gives similar results the detn. of the blood sugar is not of value in differential diagnosis. HARRIET F. HOLMES

"Alimentary hypoglycemia" in diabetes mellitus with and without hypertonus. E. KYLIN. *Wiener Arch. klin. Med.* 15, 325-30(1928).—The administration of 75-100g. sugar has been used by Depisch and Hasenöhrl as a functional test for the insular app. of the liver. In cases of diabetes with hypertonus there was a transitory hyperglucemia followed by a marked hypoglycemia. In cases without hypertonus there was no hypoglycemia. The "postalimentary hypoglycemia" in diabetes with hypertonus is often much greater than occurs in healthy persons. In one case of diabetes with hypertonus the administration of sugar was followed by hypoglycemic shock. It

is difficult to reconcile this finding with the theory that diabetes with hypertonus is due to a lack of insulin.

HARRIET F. HOLMES

The effect of grape sugar and insulin on the acetone and β -hydroxybutyric acid content in the blood and urine in diabetes mellitus. O. PUSKO. *Wiener Arch. klin. Med.* 15, 331-48(1928).—Glucose and insulin were injected in various combinations and at various time intervals and the effect was noted on the "acetone bodies" of the blood and urine. The acetone bodies of the blood in control tests without any therapeutic measures were found to vary at different times of the day. Sugar followed by insulin was found to give a more favorable result than insulin followed by sugar. The best results were obtained when glucose was given intravenously and followed 1.5 hrs. later by a subcutaneous injection of insulin and this measure may be of therapeutic value in the treatment of diabetes. In all cases, including the control cases there was a distinct excretion of the acetone bodies in the urine at night, 9-18 hrs. after the injection.

HARRIET F. HOLMES

Determination of biological relationship by means of skin sensitization tests.

HANS FRÖHLICH. Univ.-Hautklinik, Breslau. *Z. Immunitäts.* 55, 236-57(1928).—The biol. relationship of animals was studied by sensitizing human individuals with a subcutaneous injection of a given antiserum and after a given incubation period making skin reactions at the site of injection with the various sera to be compared. With this technic the following groupings of animals were made: (a) *Macacus rhesus* and *Macacus cynomolgus*, (b) sheep, goat, cow, (c) white rat and white mouse, (d) hen, pigeon, turkey, goose, (e) horse, mule and ass. No relationship existed between the rabbit and guinea pig and between the pike, carp and tench. Just as Uhlenhuth was able to produce antibodies in the lower monkey against human serum so human skin could be sensitized against the serum of lower monkeys, showing that the 2 classes of animals were biologically different. As a whole this method confirms the results obtained with other methods.

JULIAN H. LEWIS

Effects of injections of acid and trauma on jejunal transplants to the stomach. WILLIAM J. GALLAGHER. Univ. of Chicago. *Arch. Surg.* 17, 279-88(1928).—An artificial hyperacidity produced by injections of varying concns. of HCl once or twice daily into the stomach of 7 animals for periods of 24 to 58 days did not increase the incidence of chronic ulcer in the stomach itself, in the scar tissue of the transplant, or in the transplant mucosa.

JOHN T. MYERS

Measurements of the p_H of normal, fetal and neoplastic tissues by means of the glass electrode. HORACE MILLET. Univ. of Liverpool. *J. Biol. Chem.* 78, 281-8(1928).— p_H detns. were made on tissues by the use of a glass electrode and liquid air for freezing the tissues. The p_H of normal tissues was 7.1; of carcinomatous tissues 6.8; of human innocent neoplasms 6.92; of malignant neoplasms 6.78. The p_H of the normal tissue surrounding the innocent neoplasms was 7.1, while the p_H of the tissue around the malignant neoplasms was 7.04. Fetal rabbit tissue had a lower p_H than the maternal tissue. The p_H of the fetal tissues increased with increasing age, and 12 hrs. after birth was the same as that of fully grown animals.

C. RIEGEL

Thermic polypnea and alkaline reserve. L. AMBARD AND F. SCHMID. *Compt. rend. soc. biol.* 99, 217-9(1928).—Tests with 2 chloralosed dogs showed that 10 min. after the establishment of thermic polypnea, with the respiration raised from 16 to 240, the alk. reserve fell from 40 to 33 and from 34 to 26, resp.

L. W. RIGGS

Possible origin of uric acid. LUCIEN BERNARD. *Compt. rend. soc. biol.* 99, 314-5(1928).—The presence of uric acid in cases of hepatic insufficiency and glucosuria may be explained as follows: The degradation of glucose yields methyl glyoxal which with NH_3 and HCHO gives methylimidazole. It is suggested that methylimidazole may unite with urea and O to yield uric acid and H_2O .

L. W. RIGGS

Velocity of the oxido-reduction processes in nephritic rabbits. E. AUBERTIN, P. MAURIAC AND E. AUBEL. *Compt. rend. soc. biol.* 99, 321(1928); cf. C. A. 22, 1988. —The velocity of oxido-reduction processes in the kidney is diminished in rabbits with acute or chronic nephritis caused by injections of $UO_2(NO_3)_2$, a much greater reduction in velocity being noted in cases of chronic nephritis. The velocity of reduction in liver and muscles was not modified by nephritis even in animals with high azotemia.

L. W. RIGGS

Experimental chronic nephritis in the rabbit. PIERRE MAURIAC. *Compt. rend. soc. biol.* 99, 322-3(1928); cf. C. A. 21, 3081. —The elimination of N, albumin, glucose and the N and glucose contents of the blood were studied in rabbits with exptl. nephritis caused by $UO_2(NO_3)_2$. Ingestion of urea in 0.05 g. doses in normal rabbits but slightly affected the azotemia, but with nephritic rabbits the azotemia was increased 4-fold after 4 doses distributed over 10 days.

L. W. RIGGS

Composition of the liquid of edema in a case of "edema of Quincke." PAUL GOVAERTS. *Compt. rend. soc. biol.* 99, 339-41(1928).—Analysis of the liquid of edema in this case gave total protein 31.15 g. per l., albumins 21.35, globulins 9.8, fibrinogen traces, non-protein N 0.28. A sample of blood taken at the same time gave total proteins 69.3 g. per l., albumins 52.1, globulins 17.2, non-protein N 0.21. L. W. RIGGS

The Meinicke micro-reaction. DAVID PRENTICE. *Lancet* 1928, I, 493-4.—The serum in this reaction can be collected from a finger prick. The antigen is a cholesterol-free ext. of horse heart muscle with the addn. of balsam of tolu. The technic is described. There is a high percentage of agreement with the Wassermann reaction and the no. of those diagnosed as syphilitic has almost doubled. F. B. SEIBERT

Immunity and vitamin deficiency. A review of the evidence. ANON. *Lancet* 1928, I, 670.—The literature is reviewed in regard to the various diseases which are related to vitamin-A deficiency. Mortality in certain diseases seemed to be decreased also by the administration of vitamin D. The relationship of tuberculosis to vitamin deficiency is so far indefinite. P alone out of the following list—Ca, Fe, K, Cl, P, Na, certain amino acids, antiscorbutic, antineuritic and fat-sol. vitamins—had an effect in lowering the titer of agglutinins and amboceptor. F. B. SEIBERT

Some effects of alteration of oxygen pressure in the inspired air upon cancer growth and body weight of rats and mice. J. ARGYLL CAMPBELL AND W. CRAMER. *Natl. Inst. Med. Res. Lancet* 1928, I, 828-30.—Rapidly growing implanted tumors in rats and mice show a greatly diminished rate of growth and extensive necrosis during prolonged exposure (2 weeks) of the animals to low O pressure, confirming Warburg and his collaborators. The normal O pressure is about 21% atm.; low O pressure used was 10% atm. or less; high O pressure used was about 60% atm. Exposure to high pressure produced no effect. The decrease occurring under low pressure is accompanied by a decrease in growth of the normal body tissues. There is no evidence that variations in O pressure in the inspired air is of therapeutic value. F. B. SEIBERT

Fermentation and growth. OTTO ROSENTHAL. *Z. Krebsforsch.* 27, 125-31 (1928).—A general discussion of recent observations with particular bearing on the problem of cancer growth. No new material is given. H. G. WELLS

Immunological processes in malignant tumors. KARL LEWIN. *Z. Krebsforsch.* 27, 138-51(1928).—A general discussion with reports on the effects of immunization with casein compounds, Na nucleinate, yatran and silacid. These reduce the no. of successful inoculations of tumors in mice and rats. No expts. were conducted with spontaneous tumors, and the strains of inoculation tumors used had a large no. of neg. results in the controls. H. G. WELLS

The interferometer method in the diagnosis of pregnancy and malignant conditions. G. S. HAYNES AND C. G. L. WOLF. *Cambridge Eng. J. Cancer Research* 11, 301-23(1927).—The interferometer method for detg. the Abderhalden reaction has been recommended by Paul Hirsch for the diagnosis of pregnancy and of malignant growths. Much of the observed effect is found to be due to sol. substances coming from the rubber stoppers which close the incubation tubes. When the rubber is coated with sterile tinfoil, most of the differences which have been observed disappear. Conclusion: The method, either in its original form or with the subsequent precaution in technic which the authors have contrived, does not yield any useful results. H. G. WELLS

The treatment of Flexner-Jobling rat carcinomas with bacterial proteolytic enzymes. J. C. TORREY AND M. C. KAHN. *Cornell Med. Coll. J. Cancer Research* 11, 334-76(1927).—A report is made on the results of treatment of exptl. tumors in white rats with certain bacterial proteolytic enzymes. The tumors were the Flexner-Jobling carcinoma type and the proteolytic enzymes employed were those of certain spore-bearing anaerobes (*B. sporogenes* and *B. histolyticus*). The purpose of the study has been to find a tissue-destroying agent of bacterial origin which would have a selective action, at least in some degree, on tumor cells and which might eventually be applied to certain types of human neoplasms. Whole broth cultures of *B. histolyticus* will produce an energetic digestion of tissue in whatever part of the animal body it is injected. The problem, thus, has been to hold in check or limit this proteolytic activity so that it may be confined wholly or in large part to the neoplastic tissue. With sterile filtrates of 24-hr. *B. histolyticus* growths in this medium injected directly into the rat tumors, "cures" may be achieved in 25 to 50% of animals in which the growths have not reached a diam. greater than 2 cm. This result depended on the presence of a few living bacteria. A drawback in the exptl. treatment of tumors by this method is encountered in the immunity factor. It is necessary to accomplish the complete destruction of the tumor tissue within a week or 10 days, otherwise an immunity to the proteolytic enzyme will begin to appear and subsequent injections will have little or no effect. H. G. W.

Chemotherapeutic attempts with coal-tar derivatives on spontaneous mouse tumors. MILLARD C. MARSH AND BURTON T. SIMPSON. N. Y. State Inst. Study Malignant Diseases, Buffalo. *J. Cancer Research* 11, 417-35(1927).—145 chem. compds., nearly all found in or derivable from coal tar, were administered to mice bearing spontaneous mammary tumors during an av. period of 34 days for each case, by intravenous and subcutaneous injections. The compds. are dyes and their antecedents—hydrocarbons, bases, acids and "intermediates" of industrial chemistry—together with a few miscellaneous org. compds. and solvents. All yielded neg. results. The highly toxic org. compd., Pb tetraethyl, has a regressive action on the mouse tumor, perhaps equal to that of colloidal Pb. It is hardly to be exhibited except by lethal doses.

Agglutination by precipitin. II. F. S. JONES. Rockefeller Inst. *J. Exptl. Med.* 48, 183-92(1928); cf. *C. A.* 21, 3082.—Collodion particles sensitized with various proteins adsorb sufficient protein to agglutinate in the presence of precipitin sp. for the adsorbed protein. The amt. of adsorption, judged by agglutination, is not dependent on the concn. of the sensitizing protein beyond a certain max. The agglutination resulting from the addn. of immune serum to particles sensitized with protein is immunologically sp. Particles exposed to a no. of antigenic substances in succession are agglutinated by all of the appropriate antisera. Particles exposed to immune serum and subsequently washed fail to agglutinate in the presence of antigen, although some of the protein constituents of the immune serum are fixed upon them and its antibody content diminishes.

Immunological studies in relation to the suprarenal gland. III. Effect of injection of adrenaline on the hemolysis formation in normal rats. J. MARMORSTON-GOTTESMAN AND DAVID PERLA. Montefiore Hospital. *J. Exptl. Med.* 48, 225-33(1928).—Large amts. of adrenaline injected repeatedly before and after the injection of antigen depress the antibody-forming capacity of normal adult albino rats to a marked degree. The depression in antibody formation is roughly proportional to the quantity of adrenaline injected. Small quantities have no detectable effect on antibody formation.

Bacteriophage of d'Hérelle. IX. Evidence of hydrolysis of bacterial protein during lysis. D. M. HETLER AND J. BRONFENBRENNER. Rockefeller Inst. *J. Exptl. Med.* 48, 269-75(1928).—During the process of lysis of bacteriophage, there is an appreciable increase in the amt. of free NH_2 acid present in the culture, which is due to hydrolysis of bacterial protein. X. Toxin production by normal and by phage-resistant Shiga dysentery bacilli. RALPH S. MUCKENFUSS AND CHARLES KORB. *Ibid* 277-83.—The production of exotoxin and of endotoxin by normal Shiga dysentery bacilli and by strains resistant to Laudman phage was found to be the same. The presence of phage did not alter toxin production by the resistant organism. C. J. W.

The van den Bergh reaction for serum bilirubin with notes on interpretation and technic. W. W. HALL. *J. Lab. Clin. Med.* 12, 529-35(1927). E. W. W.

SAINT-LAURENS, GERMAINE: De l'opacité des calculs biliaires aux rayons x et leur composition chimique. Paris: Arnette. 132 pp. P. 13.

H—PHARMACOLOGY

A. N. RICHARDS

Morphine treatment and epilepsy by excitation in dogs. G. AMANTEA AND G. MARTINO. *Boll. soc. ital. biol. sper.* 2, 311-6(1927).—Dogs were found to tolerate up to 6 cg. per kg. of weight of morphine injection subcutaneously, without showing any symptoms of epilepsy. But when treated with strychnine as well, even dogs not susceptible showed symptoms of epilepsy.

The change in glucose content of the blood by the effect of strychnine. V. ZAGAMI. *Boll. soc. ital. biol. sper.* 2, 320-3(1927).—Rabbits were treated subcutaneously with doses of strychnine varying from 0.1 mg. to 0.6 mg. In most cases the glucose content of the blood increased from 1% to as high as 29% in 15 min., the av. being about 10%. In one-half hr. a max. of 52% was reached in one case, the av. being about 25%. The glucose content gradually drops back to normal, which results after about 2 hrs.

The pharmacology of Chinese aconite, T'sao-wu-t'ou. HUNG-PIH CHU. *Chinese J. Physiol.* 1, 7-14(1927). E. J. C.

Feeding experiments with lead. H. MIESSNER. *Tierärztl. Hochschule Hannover. Deutsch. tierärztl. Wochschr.* 35, 297-301; *Chem. Zentr.* 1927, II, 123.—Expts. are described in which domestic animals were fed chem. pure Pb, PbO, natural galena contg. As and PbSO₄. Hens and ducks succumbed after 65 g. of chem. pure Pb had been given

in large doses, and sheep after a total of 121 g. Goats and cattle tolerated doses of 86 and 83 g., resp., without injury, when administered in small doses. PbO is 2-3 times as poisonous as pure Pb . With respect to sensitivity to PbO , cattle are the most sensitive, followed by goats, ducks and hens in the order named. Galena, in spite of its As content, was tolerated relatively well by all the animals. After feeding 100 g. of galena, an ox was not taken ill, while a young calf succumbed after 7 days to 150 g. $PbSO_4$ is harmless. The Pb present in waste waters in the vicinity of Pb mines is probably in the form of PbO , and in such form is taken in by the animals, partly from the water and partly from the soil.

C. C. DAVIS

The pharmacology and toxicology of oil of turpentine and of terpenes. HERMANN KUNZ-KRAUSE. *Festschrift A. Tschirch* 1926, 121-35; *Chem. Zentr.* 1927, I, 2927.—With the aid of numerous examples, the now harmless and then toxic course of action of oil of turpentine and of terpenes is shown. The toxic action is greater when they are absorbed by respiration than when they are taken into the stomach. From the different phases during the course of the poisoning, 2 complex effects are to be distinguished, the cerebral effect and the irritant effect. These effects were studied with a view to explaining etiologically the effects by the phys. or phys.-chem. properties of the oil of turpentine. Because of the high d. of oil of turpentine, the blood corpuscles are stifled, the CO_2 in the blood increases and lactic acid is formed, upon which the cerebral phenomena depend. The irritant effect is a result of the high absorptive capacity of oil of turpentine for O, and of the catalytic action. O_3 and H_2O_2 are formed, as a result of which oxidative irritation sets in. Because of the poisonous action of the levogyrotary synthetic camphor prepd. from *l*- α -pinene, the varied course of the phenomena of poisoning is attributed to the difference in the poisonous properties of *d*- α - and *l*- α -pinenes. This would explain the common idea of the non-poisonous nature of American turpentine, which consists solely of *d*- α -pinene.

C. C. DAVIS

The behavior of arspphenamine and of neoarsphenamine in the organism. I. ABELIN. *Festschrift A. Tschirch* 1926, 370-6; *Chem. Zentr.* 1927, I, 2925.—As a result of researches of A. and of other investigators on the behavior of arspphenamine and of neoarsphenamine in the organism, it is concluded that each substance is in part eliminated in its original form. That part not eliminated immediately after injection leaves the blood stream very rapidly and penetrates the organs and tissues where it is completely decomposed. Arspphenamine was identified by the red color which appears after diazotization and coupling with resorcinol (cf. Remy, *C. A.* 17, 3351).

C. C. D.

Aromatic nitro and amino compounds as blood poisons. W. LIPSCHITZ. *Zentr. Gewerbehyg. Unfallverhüt.* 14, 11-4; *Chem. Zentr.* 1927, I, 2752.—Both NO_2 and NH_2 compds. cause methemoglobinemia as the chief symptom. Not only different animals but individual workers are differently affected, probably because of the widely varying gas exchange. H_2O accelerates the reabsorption of benzenes contg. N. Quinine and administration of O are remedies. The effect of *m*- and *o*-compds. and their substitution products, their elimination in the urine, and the different reactions of different kinds of blood are described. In case methemoglobin formation does not exceed 60%, reformation by reducing cells occurs, which in expts. on animals was promoted by the injection of $Na_2S_2O_3$.

C. C. DAVIS

Dynamics of the heart. III. Dynamical analysis of the action of digitalis on the heart. NORIMI ISHIDA. Imp. Univ., Kyoto, Japan. *Acta Schol. Med. Univ. Imp. Kioto* 9, 391-420 (1927).—When digitalis preps. (digitin, digifolin, cynarin, helleborein, convallin) or $BaCl_2$ was introduced into the perfusion fluid of a heart, there was an increase in diastolic capacity, a decrease in systolic capacity and an increase in the max. of the intracardiac pressure. These changes are traced to an increase in absolute contractility of the heart muscle and a decrease in its tonus. However, the increase in diastolic capacity can only increase the intracardiac pressure slightly if at all.

H. J. DEUEL, JR.

The action of acids and bases on cardiac muscle tone in anodon. M. DU BOISSON. Univ. Ghent, Belgium. *Arch. intern. physiol.* 29, 22-4 (1927); *Physiol. Abstracts* 13, 24.—In acidosis (HCl or $CH_3CHOHCOOH$) systole was greater and diastole was decreased while in alkalosis ($NaHCO_3$ or neutral Na_2CO_3) the reverse was true.

H. J. DEUEL, JR.

Ethylene-oxygen anesthesia with reports of 521 cases at Letterman General Hospital, U. S. Army. JOHN D. BRUMBAUGH. *Military Surgeon* 63, 32-45 (1928).—The disadvantages of this method of anesthesia are the explosibility of ethylene and the oozing of the wounds which is slightly more than with other anesthetics. This latter feature, however, is minimized since the effect ends immediately on the cessation of the administration of the ethylene. On the other hand the advantages are the ease

of induction and the rapidity of recovery, the lack of effect on the pulse, and blood pressure (there may be a slight elevation of the latter) and the kidney, a decreased incidence of sweating and gas pains, and a lessened incidence of vomiting and of post-operative pneumonia. There is also practically no effect on the blood sugar. H. J. D., Jr.

Tobacco and blood sugar. A. CAPONNETTO. *Klin. Wochschr.* 7, 701(1928).—Smoking increases the blood-sugar concn. 0.4 to 0.5 g % in diabetics. The highest values are obtained about 2 hrs. after smoking. The intramuscular administration of 0.001 g. nicotine leads, after 1½ hrs., to a rise of 0.9 to 1.0 g. % in the blood-sugar concn. The hyperglucemic action of the nicotine can be depressed with atropine or with ergotamine. MILTON HANKE

The influence of pancreas preparations on the disturbance of food resorption in pancreasectomized dogs. MARTIN NOTHMANN. *Klin. Wochschr.* 7, 886-8(1928).—Pankrophorin, a powerful pancreas prepn., when fed with a normal diet to pancreasectomized dogs, leads to a disappearance of fat and muscle fibers from the feces. MILTON HANKE

The presence of caffeine in the milk of women after drinking coffee. E. SCHILG AND R. WOHINZ. *Arch. Gynäkol.* 134, 201-4(1928).—After the ingestion by nursing mothers of 15-g. coffee, containing 99-mg. caffeine, 1% of the caffeine was found in the milk. HARRIET F. HOLMES

Calcium and cardiac output. S. LAUTER AND BAUMANN. *Deut. Arch. klin. Med.* 155, 222-34(1927).—The intravenous injection of 5 cc. 10% CaCl_2 was followed in 80% of the cases studied by a slower pulse rate. No regularity was observed in the amt. of slowing, or in the no. of min. required for the normal rate to be reattained. In a few cases the rate was faster after the injection. Only slight and irregular changes were noted in the blood pressure; frequently the blood pressure remained const. after injection. As a control, no effect was noticeable after the injection of NaCl soln. The cardiac output was detd. by the EtI method of Henderson and Haggard. In more than half the cases there was an increase in the cardiac output, the max. increase being 70%; in 27% a decrease, the max. being 19%. The vol. per min., or product of pulse vol. and pulse rate, varied from +54.5% to -26.5%; in 12 cases there was an increase, in 14 a decrease. P. Y. JACKSON

The chemotherapeutic action of a new gold preparation (Orosan) in tuberculosis. P. RONDONI. *Biochim. terap. sper.* 14, 257-73(1927).—Colorless, clear solns. of 0.1% and 0.086% Orosan (I) ($\text{Na}_2\text{Au}(\text{SO}_3)_4$; cf. Oddo, Mingoa *C. A.* 22, 1553) turn red and turbid on 45 min. heating to 100° or 10 min. autoclaving at 130°. Under the same conditions 0.1, 0.5 and 1% solns. of *Sanocrysin* (II) turn distinctly brown. Boiled solns. of either prepn. had no inhibiting effect on *B. tuberculosis* cultures. Emulsions of tubercle bacillus were completely lysed by 0.5% II and 0.4% I. Above these concns. I is somewhat superior to II; below the reverse is the case. The growth of a broth-glycerol (5%) culture of human tubercle bacillus was suppressed by a 1:5000 soln. of I and inhibited for 1 week by a 10⁻⁴ soln. A concn. of 1:40,000 had a noticeable effect. Rabbits tolerate 50-60 mg./kg. intravenously, with only a slight indication of renal lesions. In guinea pigs repeated subcutaneous injections of 5-6% solns. into the same spot did not produce local inflammations. Intraperitoneally administered, the max. tolerated dose is 0.1 g./kg., the m. l. d. 0.2 g./kg. Individual variations and acquired tolerance were observed. The degenerative and hemorrhagic lesions of liver and kidney are relatively inextensive, suggesting that death is caused by central nervous or capillaritoxic action in the sense of Heubner. Guinea pigs infected with a virulent strain of human tubercle bacillus tolerated 1.35 g. I per kg., given subcutaneously or intraperitoneally within 80 days, or over 15 mg./kg. daily. Unlike II, I is better tolerated by the tuberculous than by the normal organism. The therapeutic effect was very moderate and limited to the promotion of proliferative and calcification processes. M. J.

Pressure changes in the capillaries of human skin due to electrically applied medicaments. Action of alcohol, quinine and atropine. LUDOLPH FISCHER. *Z. Biol.* 87, 197-209(1928).—There is effected a hyperemia and increase in capillary pressure. The greatest effect is obtained with quinine. FRANCES KRASNOW

Further studies on the influence of parasymphathicotropic and sympathicotropic drugs on "Thyraden" and natural metamorphosis. OTTO GETZNER. *Z. Biol.* 87, 228-38(1928).—That muscarine, pilocarpine and acetylcholine inhibit the metamorphosis and "Thyraden" action of *Alytes* larvae and that atropine accelerates these processes is applicable also to the frog and food larvae. Choline has the same effect as acetylcholine. Ergotamine acts like atropine. FRANCES KRASNOW

The combined action of veratrin and curare on striated frog muscle. II. The electrogram. JULIUS GRUNDIG. *Z. Biol.* 87, 240-8(1928); cf. *C. A.* 22, 1805. F. K.

The thermodynamics of acid and alkali contraction of collagen tissue. The thermic tension coefficient of isometric contractions. EDGAR WÖHLISCH. *Z. Biol.* **87**, 353-63 (1928).—Expts. on tendon show that the isometric strength increases with increasing temp. in the presence of lactic and acetic acids, whereas in the presence of alkali it decreases. The contraction is not in the muscle fibers themselves but in the contained collagen.

FRANCES KRASNOW

The thermodynamics of muscle contraction. I. The thermic strength coefficient of acid and chloroform contraction and rigor mortis. EDGAR WÖHLISCH AND RENÉ DU MESNIL DE ROCHEMONT. *Z. Biol.* **87**, 364-76 (1928).—The contraction of muscle due to lactic and acetic acids has a positive coeff., an anomalous thermoelastic behavior. This effect is similar to that shown by collagen. CHCl_3 contraction proceeds in 2 stages, showing 2 temp. coeffs. The positive coeff. is, in all probability, chem., the negative one, phys. In rigor mortis the thermic strength coeff. is negative.

FRANCES KRASNOW

Methods and results of experiments on the effects of drugs on bird malaria. ROBERT HEGNER, EDWIN H. SHAW, JR. AND REGINALD D. MANWELL. *Am. J. Hyg.* **8**, 564-782 (1928).—Birds may be used in the trials of new therapeutic agents for malaria since the drugs of the quinine type have a similar effect on avian and human parasites. Quinine is the most effective drug in malaria. It is assumed that the parasite is within the cells of the host and the drug must penetrate the cell in order to be effective; its toxicity must be much greater for the parasite than for the host. The toxicity of the drugs was measured before administration against *Paramecium caudatum* in a medium of H-ion concn. 8.2. The partition coeff. of the drug between erythrocytes and a medium surrounding them was ascertained by the Shaw method. Drugs insol. in the erythrocytes were incapable of action against malaria. Compds. which do not yield ions at the neutral point are absorbed by erythrocytes while those yielding ions are not absorbed. Canaries were infected with *Plasmodium cathemerium* by injecting the parasite intramuscularly or intraperitoneally. The drug treatment was begun on the day after the inoculation and the lapse of time before the appearance of the parasites noted. Six series of drugs were tested. Quinine and plasmochin were the most efficient while mercurophen appears promising. Thirty-two references are given. G. H. W. L.

The absorption of chemical compounds by red blood corpuscles and its therapeutic significance in the treatment of bird malaria. EDWIN H. SHAW, JR. *Am. J. Hyg.* **8**, 583-603 (1928).—Measurements of the absorption of various compds. by red blood cells of chicken and man were made *in vitro*. Ninety cc. of blood were treated with 10 cc. of 10% Na citrate and then centrifuged. Following this they were washed 5 times in a physiol. salt soln. during which time the white corpuscles were removed. The washed red corpuscles were suspended in the physiol. salt soln. and the vol. was brought up to 70 cc. To 10 cc. of this suspension were added 10 cc. of 6-10,000 soln. of the compd. in the original physiol. soln. After 30 min. of gentle rotation the sample was centrifuged and the clear liquid was compared with that of a control in an interferometer. This technic is applicable to any colorless compd. The partition coeff. is calcd. thus: concn. in corpuscles/concn. in salt soln. Measurements of the absorption by red blood corpuscles were made on cinchona, quinoline, and pyridine derivs. and on dyes. Conclusions are drawn as to the effects of changes in structure on the partition coeff. between corpuscles and salt soln. As proof that the absorption is a true partition desorption expts. were performed with pyridine and quinoline. The absorbed compd. is not firmly bound by the corpuscles but is readily given off and is free to act on the malarial parasite.

G. H. W. LUCAS

Action of camphor on the frog heart. HARUYOSHI YOSHIDA AND INOSUKE HAYASHI. *Nagoya J. Med. Sci.* **2**, No. 1, 1-5 (1927).—Expts. were made on isolated frog's heart by the Straub method using a Locke-Ringer soln. contg. camphor in concn. 1×10^{-3} to 2×10^{-4} . Low dilns. 1×10^{-6} had practically no effect while dilns. of 1×10^{-3} caused the heart to stop in diastole. Poisoned hearts could be washed free from camphor and would recover; if left standing from 3 to 25 hrs. without washing there was spontaneous recovery depending on the degree of oxidation. Colorimetric detns. of the camphor were made in the test solns. Six tracings are given. G. H. W. L.

The relationship between the chemical constitution and pharmacological action of local anesthetics. I. Comparative experiments of novocaine, tutocaine, cocaine and psicaine. KINGO TOMINAGA AND INOSUKE HAYASHI. *Nagoya J. Med. Sci.* **2**, No. 1, 6-10 (1927).—From Willstätter's formula for cocaine it is evident that 12 stereoisomers are possible; expts. on 6 of these show that there is a real quant. difference in their anesthetic action. Modifications of the formula for tropacocaine are discussed and 9 conclusions are drawn as to the effects of changing groups, etc. Phys. properties such as soly., m. p., f. p. and H-ion concn. show no specific dependence on the chem. consti-

tution. Novocaine and tutocaine show similar color and pptn. reactions while cocaine and psicaine react somewhat differently. The pharmacol. action of the drugs was tested on hemolysis, wheal formation on man, surface anesthesia on rabbit ear; the toxic effects were measured on mice. Tables are given. Conclusions: Novocaine, tutocaine, cocaine and psicaine show no remarkable difference in phys. properties. From the chem. standpoint novocaine and tutocaine are closely related; cocaine and psicaine are not so much so. In pharmacol. action cocaine and psicaine are very similar; tutocaine is weaker than either and in its poisonous action psicaine lies between tutocaine and novocaine. A parallelism does not always exist between the relationship of chem. constitution and the similarity of pharmacol. action in the local anesthetic of the benzoyl ester of *p*-aminobenzoyl ester series.

G. H. W. LUCAS

The effect of insulin injected directly into the renal artery upon the nitrogen and sugar elimination of the phlorhizinized dog. JACOB GOLDSTEIN and DORAN J. STEPIENS. Proc. Am. Physiol. Soc., *Am. J. Physiol.* **81**, 480(1927).—When insulin was injected slowly into the right renal artery of a phlorhizinized dog there was a prompt decrease in sugar elimination and increase in N excretion by that kidney. There was no change in the compn. of the urine from the left kidney for some time, until the insulin had time to reach it in sufficient concn.

J. F. LYMAN

The effect of calcium on the toxicity of carbon tetrachloride in dogs. ANNE S. MINOT. Proc. Am. Physiol. Soc., *Am. J. Physiol.* **81**, 502(1927).—Even large doses of CCl_4 produced no outward signs of intoxication in dogs fed well-balanced diets, though functional tests showed some liver injury. Dogs on low-Ca diets were killed in coma or convulsions by similar doses of CCl_4 . The symptoms were relieved by repeated intravenous injections of CaCl_2 or by NH_4Cl given by mouth. Death seemed to be due to a lack of Ca ions in the blood.

J. F. LYMAN

Action of myrtilin in pancreatic insufficiency. LEONARD BENJAMIN SHIPNER. Univ. of Chicago. *Am. J. Physiol.* **84**, 396–400(1928).—Myrtilin lowered the hyperglucemia and glucosuria in depancreatized dogs, prevented the high blood sugar and urinary sugar in dogs after removal of 95% of the pancreas and restored carbohydrate metabolism to normal in dogs after removal of 88% of the pancreas and the administration of dried thyroid.

J. F. LYMAN

The mechanism of the strophanthin mydriasis in the rat. ROBERT D. BARNARD. Univ. of Chicago. *Am. J. Physiol.* **84**, 407–9(1928).—The dilatation of the pupil of the rats eye by strophanthin is thought to depend on its power to lower surface tension rather than to a sp. effect. Other substances also lowering surface tension and having a similar effect on the eye are digitalis, saponin, Na taurocholate and resorcinol.

J. F. LYMAN

The effects of some diuretics on the urea-excreting capacity of the kidney. W. SCOTT POLLAND. Stanford Univ. Med. School. *Am. J. Physiol.* **85**, 141–8(1928).—All of the xanthin diuretics increased the urea-excreting capacity of the kidney, theophylline being most powerful, caffeine less so and theobromine least. HCl and NaHCO_3 given by mouth each increased urea excretion by the kidney. Novasurol, given intravenously, markedly depressed urea excretion.

J. F. LYMAN

Effect of ether anesthesia on some blood constituents. H. E. MAGEE and MISS A. E. GLENNIE. Rowett Inst., Aberdeen. Proc. Physiol. Soc., *J. Physiol.* **64**, x(1927).—During ether anesthesia in fasting rabbits there was an increase in blood acidity, reaching a max. in about 15 min., and then slowly returning toward normal. Luorg. P was nearly always definitely increased, while serum Ca was slightly lowered.

J. F. L.

The effect of injections of pituitary extract, adrenaline and insulin on ketonuria. J. H. BURNS and H. W. LING. Proc. Physiol. Soc., *J. Physiol.* **64**, xxii(1927).—Ketonuria in rats, fed a ration of filtered butter during May and June (period of greatest ketonuria), was suppressed by injections of pituitary ext. or by adrenaline. Insulin produced a primary rise in ketonuria followed by a fall, and finally by a second rise and then by a return to normal conditions.

J. F. LYMAN

The influence of ether anesthesia upon the gaseous composition of the blood. N. E. PRITT. Proc. Physiol. Soc., *J. Physiol.* **64**, xxiv(1927).—In anesthetized blood through which air was bubbled there was a decreased rate of O_2 absorption and an increased rate of loss of CO_2 as compared with normal blood.

J. F. LYMAN

The action of insulin and sugar on the respiration quotient and metabolism of the heart-lung preparation. L. E. BAYLISS, E. A. MÜLLER and F. H. STARLING. Univ. Coll. London. *J. Physiol.* **65**, 33–47(1928).—App. is described for ventilating the lungs with a small const. quantity of air in which the amts. of O_2 and CO_2 are kept const. by adding the first as fast as it is used up and removing the second as rapidly as it is formed. The respiratory quotient of the heart and lungs was not greater than 0.95,

probably less. In the absence of insulin enormous concns. of glucose were needed in the blood in order to permit the heart to function properly, and subsequent addition of insulin caused a rapid disappearance of glucose occurring only when the glucose concn. was initially greater than 0.5%. The glucose that disappeared was not oxidized. A reaction is suggested: free glucose (+ insulin) \rightarrow glucose complex. The glucose complex formed in the above reaction constitutes the actual material used by the heart muscle cells to provide energy for their contraction. Insulin may be a (1) reactant or (2) catalyst in the above reaction. Insulin and glucose had no specific effect on metabolism of the heart-lung prepn., since they only changed it if the heart vol. changed at the same time.

J. F. LYMAN

The action of insulin on the perfused mammalian liver. R. BODO AND H. P. MARKS. Natl. Inst. Med. Research, London. *J. Physiol.* 65, 48-62(1928).—A technic is described for isolating dog liver and perfusing it through the hepatic artery and portal vein with defibrinated blood which was ventilated by perfusion through isolated dog lungs. Glycogen storage in the absence of insulin was observed. Added insulin either stopped glycogen storage or caused a breakdown of glycogen. Added adrenaline caused a rapid breakdown of glycogen, which was not abolished by the previous addn. of insulin. The new formation of sugar by the liver of a fat-fed animal was not affected by insulin.

J. F. LYMAN

The relation of synthalin to carbohydrate metabolism. R. BODO AND H. P. MARKS. Natl. Inst. Med. Research, London. *J. Physiol.* 65, 83-99(1928).—Synthalin (decamethylenediguanidine, *C. A.* 21, 772) produced in the normal animal a rapid fall in blood sugar to a fatally low level. Two actions are involved: (1) an increased sugar disappearance; (2) a direct action on the liver shown by a rapid depletion of its glycogen and a failure of the liver to react to adrenaline. The disappearing sugar was not burnt since the respiratory quotient fell. A production of lactic acid was observed and this is the most important of its effects on carbohydrate metabolism. Synthalin had a toxic action on the liver and circulatory system.

J. F. LYMAN

The effect of insulin on acetonuria. J. H. BURN AND H. W. LING. Pharmaceutical Soc. Gt. Britain, London. *J. Physiol.* 65, 191-203(1928).—Rats fed a ration of butter and salts excreted much more acetone bodies in the summer than in the winter. Insulin injections at both seasons increased this ketonuria. Insulin injections delayed the formation of liver glycogen in fat-fed rats, the delay in the rise of liver glycogen corresponding in time to the period in which insulin augmented the ketonuria. The results indicate a transformation of fat into liver glycogen in rats on butter rations.

J. F. L.

The effect of insulin on protein metabolism. VRON C. KIRCH AND JAMES M. LUCK. Stanford Univ. *J. Biol. Chem.* 78, 257-64(1928).—The effect of insulin on protein metabolism in rats was studied by analyzing the entire animal for urea and amino acid N after the injections. Animals receiving insulin had a higher urea content, and lower amino acid N content than control animals given injections of NaCl. Conclusion: Insulin increases amino acid catabolism and inhibits protein hydrolysis.

C. RIEGEL

The effect of morphine and papaverine upon the peristaltic and antiperistaltic contractions of the ureter. CHARLES M. GRUBER. Washington Univ. *J. Pharmacol.* 33, 191-9(1928).—Strips of pig ureter were suspended in Tyrode-Locke soln. When morphine sulfate was added to the soln. in which the pace-maker end of the segment was suspended peristaltic activity was increased if it existed originally, or antiperistalsis, if it existed originally. If morphine sulfate was added to the dependent segment peristalsis is converted into antiperistalsis, and *vice versa*. Papaverine added to the soln. bathing the pace-maker causes reversal of movement also. It depresses both peristalsis and antiperistalsis and exerts this action in the presence of 100 times the quantity of morphine.

C. RIEGEL

A note on the influence of sodium phenobarbital upon the peristaltic and antiperistaltic activity of the ureter. CHARLES M. GRUBER. *J. Pharmacol.* 33, 201-6(1928).—Na phenobarbital added to the soln. bathing the pace-maker caused a depression in contractions, and the production of antiperistalsis if peristalsis previously existed, and *vice versa*. Na phenobarbital added to the bath of the dependent segment affected only the height of contractions.

C. RIEGEL

Variations in blood pressure on repeated administration of *l*- and *dl*-ephedrine. K. K. CHEN. Johns Hopkins Univ. *J. Pharmacol.* 33, 219-35(1928).—Repeated injections of *l*-ephedrine, *dl*-ephedrine or of the two alternately into anesthetized, decerebrated or pithed cats, dogs or rabbits caused a gradual decrease and a reversal of the pressor effect, the response depending on the size of the dose, time interval between injections, and the rate of injection. The gradual loss of pressor effect is attributed to failure of cardiac stimulation, and the reversal effect to cardiac depression. In one

case of bronchial asthma in man, the 1st dose of *l*- or *dl*-ephedrine by mouth caused the greatest rise in blood pressure, two subsequent doses causing smaller increases. C. R.

A comparative study of synthetic and natural ephedrines. K. K. CHEN. Johns Hopkins Univ. *J. Pharmacol.* 33, 237-58(1928).—Synthetic ephedrine, in its action on blood pressure, on strips of guinea-pig uterus, on blood sugar, and its action after arecoline or physostigmine, and in its mydriatic action, resembled natural ephedrine. The *m. l. d.* in rabbits by intravenous injection for both synthetic and natural ephedrines was 60 mg. per kg. In cases of congested nasal mucous membranes, and of hypertrophied turbinates the action of the synthetic ephedrine was similar to the natural. In about 50% of the cases of bronchial asthma studied synthetic ephedrine gave relief, but the action was weaker than that of the natural ephedrine. C. RIEGEL

The seat of the emetic action of the digitalis principles. NATHAN B. EDDY AND ROBERT A. HATCHER. Cornell Univ. *J. Pharmacol.* 33, 295-300(1928).—Nicotine abolished the emetic action of pure digitalis principles and of some crude preps., the effect persisting for 3 hrs. or more. C. RIEGEL

Influence of insulin on the disturbances of nitrogenous metabolism in severe diabetes. LABBÉ, FLORIDE NÉPVEUX AND HIERNAX. *Compt. rend.* 186, 1384-6 (1928).—In normal persons the azotemic index (cf. Laudat, *C. A.* 16, 1443) is 48 to 50%. In benign diabetes the ratio remains normal, but in severe diabetes it is lowered and ranges from 15.8 to 36%. The amino N of the blood is increased by 25 to 100% over the normal figure in severe diabetes, and the ratio of amino N to total N is similarly increased. The administration of insulin, in general, restores these abnormal ratios to their normal values. L. W. RIGGS

Influence of insulin on the disturbance of fat metabolism in severe diabetes. MARCEL LABBÉ, FLORIDE NÉPVEUX AND HIERNAX. *Compt. rend.* 186, 1445-6(1928); cf. preceding abstract.—In each of 13 cases observed the action of insulin tended to restore the metabolism of the fats. The acetone bodies of the blood fell to zero and at the same time the alk. reserve was raised to its normal figure. When the alk. reserve reached 50 vol the acetone bodies disappeared from the blood. The cholesterol of the blood generally fell, but in 3 out of 10 cases there was a slight rise. Sometimes a hypercholesterolemia resists the action of insulin. The lecithin content generally varied with the cholesterol. Insulin influenced the pancreatic function more rapidly with reference to fats than to proteins or even carbohydrates. L. W. RIGGS

Uterine action of uzara is not sympathomimetic. ROTHILIN AND RAYMOND-HAMET. *Compt. rend. soc. biol.* 99, 164-6(1928).—Uzara has a strong contracting action on the uterus *in vitro*. Like adrenaline, it does not act on the uterus after ergotamine, nor should it be considered as a sympathomimetic substance. L. W. RIGGS

Comparative action of insulin and decamethylenediganidine on the glycogen content of liver and muscles of the rabbit. P. RUBINO, J. A. COLLAZO AND B. VARELA-FUENTES. *Compt. rend. soc. biol.* 99, 178-80(1928).—Insulin accelerates the process of hydrolysis and utilization of glycogen of the tissues, but favors the phase of synthetic transformation which ends in the formation of glucose. Synthalin in small doses appears to inhibit this synthetic phase and diminishes the mobilization of glycogen in the liver. The muscular glycogen is not changed appreciably. L. W. RIGGS

Synergic action of adrenaline and ephedrine hydrochlorides. L. LAUNOY AND P. NICOLLE. *Compt. rend. soc. biol.* 99, 198-200(1928).—Tests with rabbits indicated that the mixt. of adrenaline and ephedrine in the proportions of 1 to 2000 and 1 to 5000, resp., causes a hypertensive action of which the intensity and duration are always greater than that caused by either alkaloid alone and often greater than the sum of their actions taken alone. When adrenaline is injected after ephedrine or *vice versa*, the vascular action is more intense than that following a repetition of the same dose of the same alkaloid. L. W. RIGGS

Action of pseudopelletierine on the cardiac pneumogastric. RAYMOND-HAMET. *Compt. rend. soc. biol.* 99, 204-6(1928); cf. Hazard, *C. A.* 21, 776, 1845.—Expts. with dogs under artificial respiration prove that pseudopelletierine paralyzes neither the vagus nerve terminations nor those of the sympathetic. Its action on the cardiac pneumogastric is analogous to that of nicotine and is not comparable to that of atropine. L. W. RIGGS

Excitability of the vomiting center in narcotized animals. Stimulating action of apomorphine associated with pentamethylenetetrazole (cardiazole). ALFRED SCHWARTZ. *Compt. rend. soc. biol.* 99, 222-4(1928).—It is possible to cause vomiting in a dog deeply anesthetized by veronal, without danger to the animal, by the combined actions of apomorphine and pentamethylenetetrazole on the vomiting center. L. W. RIGGS

Paradoxical reactions of certain secretions after an intravenous injection of acid

E. HUG AND A. D. MARENZI. *Compt. rend. soc. biol.* 99, 240-1(1928).—Chloralosed dogs weighing 15 kg. or more were injected with HCl or H_2SO_4 in varying concns. up to normal. The effects on the blood were the same as those reported by Haggard and Henderson, Winterstein and others. The action on the bile was remarkable in that the p_H , total CO_2 , and alk. reserve were increased in each of the 13 dogs tested. The ions Cl, Na and Ca remained about const. but K was notably increased. In the saliva there was a slight increase in p_H and a decrease in total CO_2 . L. W. RIGGS

Toxicity of uranyl nitrate by subcutaneous injection in the rabbit. MARCEL GARNIER, E. SCHULMANN AND J. MAREK. *Compt. rend. soc. biol.* 99, 269-71(1928); cf. C. A. 22, 2002.—The subcutaneous injection of uranyl nitrate in doses of 3 mg. per kg. in the rabbit causes a nephritis that is usually fatal in 5 or 6 days. With the dog 2 mg. per kg. is usually fatal in 10 days. In rabbits the albuminuria may exceed 0.6 g. in 10 cc. of urine and persists until death, while in dogs the albuminuria may nearly disappear before death. The vol. of urine excreted constantly diminished and sometimes ceased before death. L. W. RIGGS

Local edema caused by the injection of nephrotoxic substances. E. SCHULMANN AND J. MAREK. *Compt. rend. soc. biol.* 99, 272-3(1928).—The local edemas produced in rabbits by injections of $UO_2(NO_3)_2$, K_2CrO_4 and $HgCl_2$, resp., are compared. L. W. RIGGS

Action of decamethylenediguanidine on the glucemia of depancreatized dogs. F. RATHERY, R. KOURILSKY AND (MLLÉ.) S. GILBERT. *Compt. rend. soc. biol.* 99, 282-4(1928).—Synthalin in moderate but greater than therapeutic doses caused a hyperglucemia and an increased glucosuria in depancreatized dogs. It impeded somewhat the intense and prolonged hyperglucemia which followed the ingestion of glucose. Action of decamethylenediguanidine on the glucemia of the normal dog. *Ibid* 284-7.—With normal dogs the action of synthalin varies with the individual, now causing hypoglucemia and again hyperglucemia. The hypoglucemia may appear in 1.5 or in 24 hrs. The paradoxical hyperglucemic reaction was observed in both rabbits and dogs, and occurs usually within 0.5 to 3 hrs., but sometimes 24 hrs. after the initial phase of lowered glucemia. The action of synthalin is extremely variable on the hyperglucemia caused by the ingestion of glucose. It may increase, prolong or decrease the hyperglucemia, or may have no apparent action. These differences of action are not dependent exclusively on the size of the dose of synthalin. Contrary to insulin, synthalin is not to be considered a const. agent for the production of hypoglucemia in the dog. L. W. R.

Causes of hyperinsulinemia following intravenous injection of non-hypotensive solution of secretin. EDGARD ZUNZ AND JEAN LABARRE. *Compt. rend. soc. biol.* 99, 335-7(1928); cf. C. A. 22, 2992.—The injection of non-hypotensive secretin in a dog of which the principal pancreatic vein is connected with the jugular vein of a reactive dog causes a hypoglucemia in the latter. The present exp. was to det. if this hypoglucemia occurred after double subcardiac vagotomy of the donor animal. Double vagotomy of the donor dog does not prevent the gradual diminution of the glucemia of the receptor animal caused by the increase of insulin in the pancreatic vein of the donor by the action of secretin. L. W. RIGGS

Action of histamine and of acetylcholine on the vascular system of the kidney of the dog. E. DICKER. *Compt. rend. soc. biol.* 99, 341-5(1928).—With the isolated kidney, histamine in isotonic Locke soln. causes a fleeting increase in the output of the renal vein, always followed by a diminution in the output of the renal vein and of the collateral circulation. Acetylcholine at 1 in 100,000 isotonic Locke soln. diminished the output of the renal vein and did not sensibly affect the collateral circulation. With kidneys *in situ* histamine caused a dilatation followed by a diminution of the renal vol. and later an increase in vol. occurred but without reaching the normal vol. Acetylcholine was complex in its action and caused a passive diminution of the renal vol. immediately followed by an increase of vol. which was not proportional to the return of the carotid pressure. This occurs whether the pneumogastrics are sectioned or not. Action of excitation of the splanchnic nerve on the circulation in the kidney of the dog. *Ibid* 345-6. Reaction of the vascular system of the kidney in dogs desensitized after anaphylaxis. *Ibid* 346-7. L. W. RIGGS

Radium treatment of the nasal lesions of leprosy. R. P. SANDIDGE AND M. H. NEILL. U. S. Pub. Health Service, Pub. Health Bull. No. 168, 36-70(1927).—Ra was of value in removing the nodules of leprosy from the nasal cavity, while its effect on the leprosy bacilli in the nose was rather uncertain. G. SCHWOCH

Chemotherapy in malignant diseases, with special reference to lead. W. BLAIR BELL. Univ. of Liverpool. *Lancet* 1928, I, 164-5.—Every chemotherapeutical agent employed in malignant neoplastic disease should have 2 attributes at least: (1) the

power to arrest cell growth generally, (2) a special affinity for malignant cells and the chorionic epithelium. Both of these properties belong to a pure Pb colloid. The special chem. constitution, function or evocable reactions of the differentiated (specialized) tissue in which the neoplasm has developed, should be considered, and the Pb complex should be made accordingly. The present position of Pb therapy is discussed.

F. B. SEIBERT

Carbon dioxide thermo-saline springs in the light of modern research. ADOLF SCHOTT. *Lancet* 1928, I, 546-8.—The natural Nauheim CO₂ thermo-saline baths lower blood pressure in hypertension. There is also a decrease in pulse velocity. F. B. S.

Benzyl cinnamic ester in tuberculosis. The method of Jacobsen. H. BAINSBOROUGH. St. George's Hospital. *Lancet* 1928, I, 908-9.—Benzyl cinnamate given intramuscularly daily for 12 days and then 2 similar courses again after 15-18 day intervals caused improvement in tuberculous patients. Three typical cases are reported. No reaction follows administration.

F. B. SEIBERT

p-Phenylenediamine labyrinthitis. E. WATSON-WILLIAMS. *Lancet* 1928, I, 1123.—*p*-C₆H₄(NH₂)₂ is the essential ingredient in several popular hair dyes or "restorers." It often produces dermatitis and a selective action on the labyrinth. Several cases are cited.

F. B. SEIBERT

Carbon monoxide poisoning. H. HARTRIDGE. Univ. of London. *Lancet* 1928, I, 1137-40. The mechanism by which CO produces poisoning and the acute symptoms occurring, as well as the amt. of CO in air which is necessary to produce poisoning, are discussed. The content of CO in coal gas, producer gas, in products of incomplete combustion, in other gases and in gasoline motor exhaust are noted. Eleven tests for CO are mentioned. The prevention and treatment of acute CO poisoning, chronic CO poisoning and the medicolegal aspect are considered.

F. B. SEIBERT

Chemotherapy of malignant tumors. KARL LEWIN. *Z. Krebsforsch.* 27, 132-7 (1928).—A brief review of the topic with particular reference to L.'s work with various I compds., which are believed to offer possibilities for a successful chemotherapy of cancer. An org. compd. of I and Ce is reported to have given encouraging results.

H. G. WELLS

The toxicity of tetraethyl lead and inorganic lead salts. ROBERT A. KEOH. *J. Lab. Clin. Med.* 12, 554-60 (1927).—The toxicity of PbEt₄ was detd. for rabbits for the various methods of administration. Comparison of its toxicity with inorg. Pb indicates this toxicity is a function of its Pb content. An explanation of the delayed effect of PbEt₄ as compared with salts of Pb is offered in that it is suggested that PbEt₄ owes its toxicity to a decompn. reaction which produces H₂O-sol. compds. of Pb that are capable of coagulating proteins.

ETHEL W. WICKWIRE

Some notes on glycol; glycol-chloretone anesthesia. H. B. HAAG AND W. R. BOND. *J. Lab. Clin. Med.* 12, 882-3 (1927).—As a substitute for EtOH glycol did not have the same solvent action on the active principles of digitalis. Intraperitoneal administration of glycol to dogs of 5 cc. per kg. body wt. apparently showed no injurious effects. Intravenous injections of 1.5 cc. per kg. body wt. were tolerated with little or no discomfort. For 2 yrs. a glycol soln. of chloretone has been used as an anesthetic for dogs and cats in such lab. expts. as the use of chloretone will permit. 0.5 cc. of a 40% soln. in glycol. per kg. body wt. injected intraperitoneally suffices to maintain the animals in a satisfactory state of anesthesia, and seems to possess all the advantages and none of the disadvantages of the older 10% chloretone-olive oil solns.

ETHEL W. WICKWIRE

Studies in local anesthesia. VI. Further observations of *p*-aminobenzoate compounds on the rabbit's eye. SEYMOUR J. COHEN. *J. Lab. Clin. Med.* 12, 983-8 (1927).—The drugs, 28 in no., were prepd. in mol./concn., which corresponds to about 1.7% cocaine soln. The results indicate that the greatest anesthetic efficiency for this series of drugs occurs when the terminal amino group contains either the ethyl, propyl or butyl radicals. The introduction of the methyl radical in this terminal amino group causes a loss of the anesthetic action of the drug while the introduction of the amyl radical produces a drug that is very irritant and sometimes corrosive when compared with the same concn. of a cocaine soln. The substitution of the piperidine ring in place of the terminal amino group renders the drug much less anesthetic. The substitution of the cyclohexane radical for the alc. portion of the mol. produces a drug with strong anesthetic properties. The one phosphate salt is much less anesthetic than the hydrochloride salt.

ETHEL W. WICKWIRE

The action of indole and skatole on the heart. J. A. WADDELL AND J. A. CALHOUN. *J. Lab. Clin. Med.* 12, 991-7 (1927); cf. C. A. 21, 3977.—Indole and skatole were found to affect the hearts of cold-blooded animals more actively than those of warm; to de-

crease the amplitude and rate and even arrest the hearts of frogs, turtles, rabbits and cats; to have variable quant. results on animals of the same species; to become more effective on repetition and withdrawal is not followed by complete recovery; are antagonized by adrenaline but not by atropine; and are antagonistic in sequence but, mixed in balanced proportions, each exhibits its peculiar effect, both systole and diastole being decreased.

I—ZOOLOGY

R. A. GORTNER

Time factors in relation to the acquisition of food by the honeybee. O. W. PARK. Ia. Agr. Expt. Sta., *Research Bull.* 108, 185-225 (1928).—A scheme is detailed for the marking of individual bees with a pigment composed of white shellac with EtOH. H₂O-carriers cannot be distinguished from nectar-carriers by their appearance because H₂O and nectar are both carried in the honey-sac located inside the abdomen of the bee. To avoid the necessity of killing bees to det. the nature of the contents of the honey-sac, a simple technic was devised. The bee to be tested was held fast while the abdomen was gently pressed, thus causing the disgorging of a portion of the honey-sac on a piece of white filter paper. The nectar produced a translucent spot on the paper somewhat similar to that produced by a drop of oil, while H₂O drops left no residue. Refinements in the test allow an approx. detn. of the sugar concn. present—even as low as 2%. The sugar content of nectars from Iowa plants probably exceeds 25%. Nectar and pollen carriers make only about 10 trips per day while H₂O-carriers may make as many as 100 trips per day. The av. speed in flight was detd. to be about 15 miles per hr.

C. R. FELLERS

The extractive substances in *Octopus octopodia*. KIVOSHI MORIZAWA. Kioto Univ. *Acta Schol. Med. Univ. Imp. Kioto* 9, 285-98 (1927).—A 50-g. sample of fresh material from Akashi was placed in boiling H₂O for several min., then ground, extd. several times with warm H₂O, the exts. were treated with 20% tannin soln., filtered, the excess tannin was removed from the filtrate by treating successively with Ba(OH)₂, H₂SO₄, freshly pptd. Pb(OH)₂ and H₂S, the filtrate evapd. *in vacuo* at 40°; a large amt. of taurine (I) sepd. at this point; the filtrate was adjusted to 5% acidity with H₂SO₄, the remaining I pptd. with 30% phosphotungstic acid, washed with 5% H₂SO₄ and the ppt. decompd. with Ba(OH)₂ in the usual manner; the filtrate was made slightly acid with HNO₃ and the purine fraction (II) was pptd. with 20% AgNO₃; the filtrate was satd. with solid Ba(OH)₂, which pptd. the histidine and arginine fractions (III); the filtrate was made slightly acid with H₂SO₄, the excess Ag removed with H₂S, evapd. *in vacuo* to a small vol., adjusted to 5% acidity with H₂SO₄ and the lysine (IV) fraction pptd. with 20% phosphotungstic acid. Fraction II was sepd. (cf. Krüger and Schittenhelm, *Z. physiol. Chem.* 35, 153 (1902)) into guanine, adenine, hypoxanthine and xanthine. Fraction III was sepd. (cf. Kossel and Patten, *Z. physiol. Chem.* 38, 39 (1903)) into histidine, guanidine, cytosine and a new base, C₈H₁₈N₄O₄, which was named *octopine* and which forms a *picrate*, m. 225°, and a *picrolonate*, m. 234°. Fraction IV contains sarcosine, creatinine, betaine, *D*-alanine and probably carnitine. Attempts will be made to det. the constitution of octopine.

N. A. LANGE

Behavior of mitochondria within the living cell. E. S. HORNING. *Australian J. Exptl. Biol. Med. Sci.* 5, 143-8 (1928).—The observations were made on the behavior of mitochondria in the protoplasm of *Heterotrachea* as shown by dark ground illumination. The mitochondria are scattered throughout the protoplasm where they undergo active Brownian movements. Denser aggregations of mitochondria were near the meganucleus and the food vacuoles. This effect may be due to a surface tension phenomenon dependent upon their phosphatidal nature. The presence of mitochondria within the

food vacuoles is regarded as a direct demonstration of the origin of digestive enzymes from mitochondria. L. W. RIGGS

Variations in the protein substances coagulable by heat in the plasma of normal and sacculine *carcinus maenas*. A. DAMBOVICEANU. *Compt. rend. soc. biol.* 98, 1633-5 (1928).—The plasma proteins coagulable by heat are increased 2 to 3 times in normal over sacculine crabs, also in crabs having lost their sacculus. After removal of the proteins coagulable by heat, a corresponding increase was observed in the albumins and globulins. The p_H of the plasma remained at 7.7, and Δ changed but slightly. L. W. RIGGS

Effect of the p_H of the medium on the galvanotropism of *Paramecium*. T. MAYEDA. *Compt. rend. soc. biol.* 99, 108-10 (1928).—The *Paramecium* shows cathodic galvanotropism in distd. water. Beginning with a neutral reaction the galvanotropism is cathodic until p_H 4.0 is reached. With more acidity it is indecisive and disappears at 3.6. On the other hand as the p_H increases from 7.0 the galvanotropism remains cathodic up to 9.0 when it generally becomes anodic. Below p_H 3.2 and above 10.4 the organisms are killed. When the acidity is made by HNO_3 and the alkyl. in the same soln. is made by $Ba(OH)_2$ the galvanotropism is always cathodic. L. W. R.

Action of certain electrolytes on the polarity of *Infusoria*. PAUL ROTH. *Compt. rend. soc. biol.* 99, 144-6 (1928).—Salts of the univalent cations ($NaCl$ and KCl) act in a similar manner on the polarity of *Infusoria*, their differences of action being one of degree. Salts of bivalent cations ($CaCl_2$ and $MgCl_2$) have identical actions. They depolarize a little, but are more toxic than the salts of the univalent cations. Mixts. of salts of univalent and bivalent cations show a sharp antagonism. If $CaCl_2$ hinders the depolarizing action of KCl the latter also prevents in a measure the toxic action of $CaCl_2$. In a mixt. of the 4 salts the univalent groups slightly dominates the bivalent group. L. W. RIGGS

12—FOODS

F. C. BLANCK AND H. A. LEPPER

Analysis of some Chinese foods. A. ABEL. *J. Orient. Med.* 7, 134-5, 197-209 (1927); *Ber. ges. Physiol. expul. Pharmacol.* 44, 637.—The non-protein N of *Pien-tan*, preserved duck egg, is 0.21363%; that of fresh duck egg 0.07285%. The latter is increased to 0.23599-0.24668% by 48 hr. autolysis to 0.21213% by 48 hr. storage at room temp. and to 0.22145% by incubation. The proteolysis was possibly effected by an enzyme originally contained in the yolk although ripe *Pien-tan* contains no enzyme. *Nai-tofu*, Mongolian cheese, is one of the most important stock foods of the Mongols. It contains 8.44% water, 50.63% protein, 24.45% fat, 2.44% salts, no carbohydrates. MARY JACOBSEN

Report of the Committee on Methods of Analysis. D. A. COLEMAN, et al. U. S. Dept. Agr., Wash., D. C. *Cereal Chemistry* 5, 269-76 (1928); cf. C. A. 21, 3092.—Collaborative protein studies were made by 40 representative cereal chemists. The samples submitted for test were durum wheat (whole) and durum wheat (ground), white wheat (whole) and white wheat (ground). The range of values as given by the 40 analysts follows: for the durum (whole) 0.4%; durum (ground) 0.51%; white (whole) 0.44%; white (ground) 0.46%. Then 40 sep. portions of the durum and white wheats were ground and analyzed by the same analyst who found for the durum (whole) a range of 0.30%; the durum (ground) 0.26%; the white (whole) 0.32%; and the white (ground) 0.19% or an average of 0.27%. To check equipment and standard solns. a soln. contg. 0.5% $(NH_4)_2SO_4$ was submitted to 22 collaborators with the request that they distil and titrate, also digest, distil and titrate and multiply N by 5.7. The range here was 0.52% by both methods. Collaborative studies were also made on the analyses of feeding stuffs. Here the results for crude fiber and moisture were the least satisfactory. Nine collaborators also reported on the analysis of bran. Here again the results for crude fiber were unsatisfactory. L. H. BAILEY

Inspection of army biscuit on the basis of chemical analysis. J. STRAUB AND J. PH. PEPPER. *Pharm. Weekblad* 65, 765-76 (1928).—Discussion of the baking recipe, the losses of fat and sugar during baking, and the detn. of moisture, fat and sugar in the finished product. [Protein is not mentioned.—Abstr.] A. W. DOX

Report of Committee on Standardization of Experimental Baking Test. Present status of standard experimental baking test. M. J. BLISH, et al. Univ. Nebraska. *Cereal Chemistry* 5, 277-300 (1928).—The standard baking test (C. A. 22, 2007) is used as a basis for discussion and explanation. Certain additional and supplementary tests

are also proposed. These allow for variations in absorption, fermentation period, the use of oxidizing agents and mechanical development of the dough. If the standard method is not a precise scientific method, it at least more nearly approaches a scientific approximation than any procedure now available. The committee recommends the adoption of the proposed method as a tentative standard exptl. baking procedure by the American Association of Cereal Chemists. C. H. Bailey, C. C. Fifield and R. C. Sherwood reported on baking 51 flours by the proposed A. A. C. C. method and a method for making a commercial loaf using 350 g. flour. More than 1000 bakes were made and the results were subjected to statistical analyses which showed that the small-dough method is in no sense less satisfactory than the large-dough method. When small quantities of flour are available there is an advantage of the possibility of additional replicates, or the introduction of more variables into the manipulation of the dough. Blish calls attention to the need for an adequate standard reporting system for use in connection with the proposed standard baking procedure. Certain terms are defined and six types of loaves shown by photographs and it is tentatively suggested that these may be used as a basis for the development of a standard method of reporting. C. B. Morrison, R. M. Bohn and W. Siedhof reported on loaves having different textures and grains. Cross sections of such loaves are shown by photographs. C. G. Harrel reported on possible causes for variation in collaborative reports and mentions particularly the yeast and the fermentation. L. D. Whiting reported on the application of the proposed method to soft wheat flours and noted that a lower absorption would be necessary with the soft wheats, also a shorter period of fermentation.

L. H. BAILEY

Some application of spectrophotometric methods to baking problems. EVA L. STEPHENS, ALICE M. CHILD and C. H. BAILEY. Agr. Expt. Sta. Univ. Farm, St. Paul, Minn. *Cereal Chemistry* 5, 256-68(1928).—Color of baked cookies, as measured spectrophotometrically, is related in a measure to the color of the molasses used in the formula. Dosage of NaHCO_3 likewise exerts a substantial effect upon the color of the cookies, tending to cause them to brown, or take on a darker hue, as the quantity increased through the ordinary working proportions. Increasing the temp. at which the cookies are baked tends to increase the depth of color, or reduce the percentage of light reflected from their surface. Degree of alky. of the baked cookies is a function of (a) dosage of NaHCO_3 used, and (b) time and temp. of baking. In general, the degree of alky. (as p_H) tends to increase with increase in the NaHCO_3 dosage. When normal or optimum dosage of NaHCO_3 (3 g. per 220 g. of flour) was used, it appeared that the OH-ion concn. tended to rise in the early stages of the baking. This was followed by a decrease in the same values, probably because of the formation of acid-reacting compds. from the sugars present, which in turn either served as buffers, or tended to neutralize the alkali present.

L. H. BAILEY

Some aspects of the effect of heat upon flour. D. W. KENT-JONES. Woodlands, Ltd., Dover, England. *Cereal Chemistry* 5, 235-41(1928); cf. Berliner and Rüter, *Z. ges. Mühlenwesen* 1928, 209.—Loaf vol. is not a reliable guide as to the "strength" of a flour, especially with tin loaves as so many factors, more or less under the control of the baker, enter into the matter. By "strength" is meant the power of a dough to retain the gas produced within it. Undue prominence is given to oven-spring. Size of loaf is not so important as a dough that works well and can be handled easily. Improvement is obtained by adding 0.7% strongly heated flour to ordinary flour. This is in lieu of chemical improvers.

L. H. BAILEY

Effect of dry skim milk on baking quality of various flours. EMILY GREWE. Bur. of Dairy Industry, U. S. Dept. Agr. *Cereal Chemistry* 5, 242-55(1928).—Flour samples representing 95% flours milled from hard winter, hard spring, and soft winter wheat were used in making bread for a study of the incorporation of dry skim milk in the dough batch. Four % dry skim milk was used. Flours differ in their reaction to the use of dried skim milk in bread making. In some the baking qualities are improved, in others they are not. The hard spring wheat flours used in this expt. reacted more favorably to the use of dry skim milk than hard winter wheat flours. The range in fermentation time in which doughs give good bread is increased by the use of dried skim milk. This adds to the ease of bread manuf. and is a very important property. Lactose, which is not fermented by yeast, imparts a beautiful golden brown color to the crust of the baked loaf of bread. Forty-eight % of dried skim milk is lactose. Break and shred are improved by the use of dried skim milk. The shreds are long and smooth and there is a decrease in the tendency to break. The color of the crumb is more creamy and more glassy as a result of the use of dry skim milk. Proof period is affected by the use of dry skim milk in bread. Overproofing of milk bread is more detrimental than overproofing bread made without milk. There is a greater increase

in vol. as a result of overproofing a dough containing milk than a dough which has no milk; and with this increase in vol. there is an increase in the coarseness of the grain. Doughs containing dry skim milk proofed at 27° and 30° and at 30° and 35° were compared. When proper adjustments for time were made, with these changes in temp., similar results were obtained regardless of the proof temp. used. No harmful effects were obtained by proofing at 35°.

L. H. BAILEY

Report of the Committee on Method of Testing Cake and Biscuit Flours. MARY M. BROOKS, *et al.* Purity Bakeries Corp., Chicago. *Cereal Chemistry* 5, 301-9 (1928).—From a questionnaire the committee ascertained that practically all test labs. are making the usual routine chem. detns. of protein, ash, moisture, and occasionally acidity. There is some difference of opinion as to the worth of viscosity and H-ion detns. A baking test of some kind is usually made in addition to the chem. tests. A white shortening cake was chosen for the work of the committee. Three formulas and two procedures were used. The size of pan was considered and the following suggested: $3 \times 6\frac{3}{4}$ in. bottom measurement, $3\frac{1}{2} \times 7\frac{1}{2}$ top and $2\frac{1}{4}$ in. deep. Vol. of the pan is 52.8 cu. in. Allow 5 cu. in. for each ounce scaling weight or about $10\frac{1}{2}$ oz. for this pan. Line the pan with thin manilla paper and bake at about 375° F.

L. H. B.

Improvements in the fermentation of bread produced by (the addition of) yeast nutrients. L. ELION. *Z. angew. Chem.* 41, 230-1 (1928).—The fermentation of dough, as measured by the amt. of CO_2 evolved, is increased by the addn. to the mixing of yeast (1 g.) and flour (50 g.) of small amts. (0.1 g.) of yeast nutrients such as carbamide, peptone, asparagine and NH_4Cl , tartrate, lactate or phosphate. NH_4 phosphate gave the most marked increase, pronounced increase being also observed with the lactate. When the proportion of yeast in the mixing was increased to 3 g., the increase in fermentation produced by addn. of the nutrients was less pronounced, and a deficiency of sugar was observed. With yeast ext. in place of NH_4 phosphate fermentation was increased but sugar deficiency occurred even with 1 g. of yeast, although in the absence of the ext. sufficient sugar was always present. Addn. of "super-rapidase" produced a remarkable increase in fermentation, and this product appears to act as a sugar producer, by virtue of its diastatic properties, in addn. to functioning as a yeast nutrient.

B. C. A.

The baking powder controversy. HARVEY W. WILEY. *Science* 68, 159-62 (1928).

E. H.

Cause of "fishiness" in dairy products. W. L. DAVIES AND A. T. R. MATTICK. *Nature* 121, 324 (1928).—Butter-fat olein easily absorbs O , yielding a labile peroxide; the reaction is strongly catalyzed by salts of heavy metals, especially Cu. The nitrogenous base portion of lecithin is thereupon oxidized with the production of volatile bases (chiefly trimethylamine) and their fatty acid salts. Appreciable amts. of Cu were present in all fishy dairy products. In the absence of metallic contamination the absorption of O and development of rancidity would be slow.

B. C. A.

Parchment paper as a source of mold infection in butter. H. MACY AND G. M. PULKRABEK. Minn. Agr. Expt. Sta., *Bull.* 242, 1-23 (1928).—Areas of distinct, visible mold growth were produced on the surface of a mold-free butter by infection with spores brought into contact with the butter by contaminated parchment paper. Several weeks often elapse, depending largely upon humidity and temp. before the growth of mold becomes visible to the naked eye as deeply colored areas on the butter or parchment. Contaminated parchment paper may be rendered mold-free by complete immersion of the paper in boiling H_2O or boiling satd. brine for at least 5 min. A no. of chemicals, when in sufficiently concd. solns. and when allowed to act for sufficient periods of time, destroyed mold spores, but the objections to their use are such that none of them is recommended. Among those tested were boric, benzoic and salicylic acids, CH_3O , NaOCl , $\text{Ca}(\text{OCl})_2$, and chloramine. Traces of chemicals which may remain on the parchment papers after treatment by the methods described do not inhibit the growth of the mold on the surface of butter when the butter itself is the source of the mold, nor do these methods of treatment prevent the occurrence of moldy areas on the parchment paper. A full bibliography is appended.

C. R. FELLERS

The chemical composition of some Italian milk foods. L. SETTIMI. Univ. Roma. *Atti accad. Lincei* [6], 7, 586-9 (1928); cf. C. A. 22, 2008.—Analyses of 2 series of Roman buttermilk curds, the 1st from whole milk whey and the 2nd from skimmed milk whey, gave the following av. % comps., resp.: water 56.00, 66.30; total N substances 8.51, 8.30; sol. N substances 1.04, 1.10; fats and phosphatides 33.80, 23.50; lecithin 1.16, 0.94; lactose 0.90, 1.10; ash 0.48, 0.49; acidity (as lactic acid) 0.21, 0.23; calories per 100 g. 353, 257. The sol. N substances consist chiefly of proteoses and peptones, with traces of amino acids. The ash consists chiefly of $\text{Ca}_3(\text{PO}_4)_2$, with small proportions

of Na_2SO_4 , NaCl , KCl , K_2SO_4 , MgSO_4 and MgCl_2 . Analyses of Roman and of Cardito *mozzarella* (from skimmed milk) gave the following av. % compns., resp.: water 67.00, 61.00; total N substances 27.00, 16.00; sol. N substances 5.10, 2.15; amino N 0.25, 0.12; fats and phosphatides 3.00, 20.00; lecithin -, 1.05; lactose trace, 0.50; ash 2.42, 2.40; calories per 100 g. 139, 253. The sol. N substances were chiefly proteoses and peptones, with a small proportion of amino acids. The ash was chiefly NaCl and $\text{Ca}_3(\text{PO}_4)_2$ with small proportions of Na, K and Mg phosphates, chlorides and sulfates.

C. C. DAVIS

Chemical sterilization of milk bottles in relation to tubercle bacilli. E. M. WADE, R. W. ARCHIBALD AND H. A. WHITTAKER. State Dept. of Health, Minneapolis. *J. Bact.* 15, 189-94(1928).—The expts. suggests that under the conditions tried, CaClOCl solns. contg. even up to 500 parts per million of available Cl cannot be depended on to kill human tubercle bacilli in the app. and utensils of milk plants. Chloramine in a strength of 93 to 95 parts per million applied for 3 min. is effective. If solns. are stronger the time can be decreased.

JOHN T. MYERS

Microorganisms and the production of dahi. C. S. RAM AYYAR. *Agr. J. India* 23, 107-10(1928).—Dahi is a product made in India by curdling milk through the growth of certain lactic-acid-forming bacteria. It is prepd. by heating fresh milk to boiling, allowing it to cool to about 98-100° F. and adding a small quantity of dahi from an earlier batch. Upon standing overnight in a covered container a smooth homogeneous curd with an acid taste is produced. Examn. of dahi smears showed the presence of very long rods, short rods joined in pairs, cocci and yeast cells. In summer, dahi 24 hrs. after inoculation contains the long rods (*Streptothrix Dahi*) almost exclusively, the acidity of the product at the end of that time being 1 to 1.4%, calcd. as lactic acid, when the milk is kept at 98° F. In winter, the chief agent responsible for curdling is the short rod-type organism which grows well at 68° F. and produces 0.5 to 0.7% acid in 24 hrs. The product of low-temp. fermentation is known as "sweet dahi." A non-spore forming yeast of the *Torula* type is always assocd. with both types of lactic acid organisms in dahi. This yeast grows only in curdled milk of acid reaction and consumes the lactic acid produced by other organisms. It grows well in media contg. sucrose or glucose and does not produce alc. from any sugars. Lactic-acid-forming bacteria live longer when assocd. with this yeast because of its ability to prevent the accumulation of toxic quantities of acid.

K. D. JACOB

The accuracy of composite cream samples. W. B. COMBS, L. M. THURSTON, A. E. GROTH AND S. L. COULTER. Minn. Agr. Expt. Sta., *Bull.* 243, 1-38(1927).—The amt. of evapn. is greatest from glass-stoppered bottles. Rubber- and cork-stoppered bottles follow in order. The rubber stopper is preferred to the cork, as a small quantity of butterfat may be absorbed by the cork stopper. The composite cream sample cannot be condemned as inaccurate. Where possible, the composite cream sample should be prepd. in aliquot portions or in proportion to the weight of cream delivered. The dipper composite did not yield as accurate results as the aliquot. The operation of the Babcock test can be a more serious source of error in detg. the lb. of fat in cream than the method of prepg. the composite cream sample. The dropping of 0.5% when reading the Babcock test should never be practised where accuracy is desired. The cream producer can expect an accurate test on 60.8% of his deliveries if composites are prepd. in aliquot and in 45% of his deliveries if the dipper is used. The av. variation per 100 lb. of fat delivered is -0.745 lb. by the aliquot composite test and -1.012 lb. by the dipper composite test.

A. R. FELLERS

The manufacture of Cheddar cheese. C. P. CALLISTER. *Chem. Eng. Mining Rev.* 20, 317-9(1928).—A review.

J. C. JURRJEHS

The microflora of Gorgonzola cheese. A. DE TOMASI. Univ. Leipzig. *Centr. Bakt. Parasitenk. II Abt.* 74, 184-91(1928).—The characteristic odor and taste depend on chem. changes produced by spore-forming aerobic bacteria rather than by *Penicillium* Weidmanni.

JOHN T. MYERS

Aeration of grains. M. HIRSCH. *Wochschr. Brau.* 45, 256-9(1928).—In the aeration of stored grains the cooling, drying and washing action of the air depends on the temp., moisture and amount of air and the temp. and moisture content of the stored product. A table is given showing the interrelation of these factors.

A. SCHULTZ

Desiccating potatoes. HANS GRASSMÉ. *Z. Ver. deut. Ing.* 72, 1001-6(1928).—An historical résumé of the processes and economics of desiccating potatoes, with illustrations of the types of plants and machinery used. Even in 1806 efforts to salvage frozen potatoes were made successfully. About 1901 a new impetus was given the industry by the introduction of driers of the rotary drum type. Pressing or centrifuging ground potatoes resulted in a loss of part of the nutrients with the water; such proc-

esses were not successful commercially. Reducing the washed potatoes to a pulp and then drying on heated rollers give an excellent product. A water content of 15% or less, and the retention of the nutrients in an unimpaired and easily digestible form, are the requisites of a satisfactory product. Roll driers operate at about 80% thermal efficiency. 100 kg. of potatoes (80% H₂O) yield about 23.5 kg. desiccated potatoes and 76.5 kg. H₂O. 100 kg. of desiccated potatoes require about 36 kg. of coal (7000 cal./kg.) for drying and 14 kg. additional for power. Somewhat more than this is required with roll driers yielding a product contg. 12-14% H₂O. A (German) government questionnaire showed that the cost of operating factories was such that, on the average, potatoes costing more than 1.97 marks per Zentner (50 kg.) could not be desiccated profitably. As this price is less than the av. market price of potatoes it becomes necessary to develop methods that will operate at a lower cost. W. C. EBAUGH

Edible canna in the Waimea district of Hawaii. J. C. RIPPERTON AND R. A. GOFF. Hawaii Agr. Expt. Sta., *Bull.* 57, 1-41 (1928).—An exptl. planting in 19 months yielded 43 tons per acre. For starch manuf. the canna should be harvested in about 17 months. Analysis of the different parts of the canna plant showed in the fresh material as an av. of the tops in %, moisture 85, fat 0.09, crude protein 0.8, fiber 4.4, N-free ext. 8.2, ash 1.3, N 1.3, CaO 0.18, P₂O₅ 0.11 and K₂O 0.34. The root-stalk contained moisture 77.3, fat 0.08, crude protein 0.49, fiber 2.4, N-free ext. 19.2, ash 0.8, N 0.08, CaO 0.07, P₂O₅ 0.15 and K₂O 0.19. The residue or pulp after manuf. into starch was found to be a very useful fertilizer or feed. The process of edible-canna starch is described. C. R. FELLERS

Heat penetration in the pasteurizing of sirups and concentrates in glass containers. J. H. IRISH, M. A. JOSLYN AND J. W. PARCELL. *Hilgardia* 3, 183-206 (1928).—The rates of heat penetration in bottled sirups as affected by sugar concns., viscosity of liquids, size of bottle, and variety of sirup were detd. It was found that sugar exerted only a slight retarding effect on heat penetration at low concns. but an appreciable retarding effect at concns. above 50%, thermocouples being used. A very marked decrease in rate occurred between 60 and 70%. This was proved to be due to increase in viscosity of the solns. with increase in sugar concn. Differences in the rate of heat penetration in containers of different sizes were not very great in small containers such as pints, 8-ounce and 4-ounce bottles, but a marked difference was found in the rate between the gal. and the smaller containers. This last fact probably accounts for the greater loss by molding of fruit juice in gal. containers than in small containers inasmuch as most manufacturers give little or no greater time to gallon-size than to smaller containers. Sirups rich in pectins and gums transmitted heat very much more slowly than those poor in these constituents. This was proved to be caused by the effect of pectin on the viscosity. Pectin very greatly increased the viscosity of the sugar solns. of fruit juices and thereby greatly reduced transmission of heat by convection. Where the juice, sirup, or concentrate actually jellied, heat penetration became very slow, but was not noticeably affected by increase or decrease of the sugar content, provided the sugar content was not reduced below that required for jelly formation. C. R. FELLERS

Revolving grinder and "carrousel" heating room in the chocolate industry. ADOLF GRAUMANN. *Z. Ver. deut. Ing.* 72, 1025-6 (1928).—Great savings are effected in time, wages and power, and an improvement in quality of the product is obtained, when revolving chocolate mills are used rather than those of other types. Such a mill is described and illustrated. The chocolate must be kept at 80° for 3 to 5 days in a "heating room" with carefully regulated temperature. In place of such rooms of the ordinary type it has been found advantageous to use the "carrousel" (revolving) chamber, with pipes for heating or cooling, and with doors for introducing and removing pans of chocolate so arranged that little change of temp. occurs when these operations are carried out. W. C. EBAUGH

Determination of cacao shell. W. PLÜCKER, A. STEINRUCK AND F. STARCK. *Z. Untersuch. Lebensm.* 54, 488 (1927).—The authors claim priority for the method of detg. cacao shell by a count of the stone-cells. B. C. A.

Note on the loss of weight of onions on storage at Pusa. J. H. WALTON. *Agr. J. India* 23, 136-7 (1928).—In a 5-months' test onions stored on racks lost 58% in wt. and those stored in baskets 46%. Rotting was greater in the latter case than in the former. K. D. JACOB

Notes on the lemon industry in Italy. G. S. CHEEMA. Dept. Agr. Bombay. *Bull.* 137, 9 pp. (1927).—The principal lemon-growing districts of Italy are Sicily, Calabria, Campania, Puglie, Liguria and Sardinia. Soils suitable for growth of lemons vary rather widely in chem. and mech. compn. The percentages of acid and sugar in lemons from different provinces are: Messina 7.61, 1.55; Cantania 8.05, 1.80; Acereale

6.02, 0.63; Naples 7.43, 0.63; Sorrento 8.68, 0.55; Palermo 8.15, 0.56, resp. The *manuf. of lemon oil and citric acid* is briefly described. Statistics are given on the production and exports of lemons, lemon oil and citric acid from Italy in 1923, 1924, and 1925.

K. D. JACOB

Injury to pears by hydrochloric acid solution. F. W. PETREY. *Farming in South Africa* 3, 875, 901(1928).—There are 2 types of injury that may result from treatment of pears for the removal of spray-residue by submerging them in a weak soln. of HCl. One type consists of the collapse and blackening of the breathing pores of the skin of the fruit, and the other consists of the burning of the skin area, which turns brown. The first type of injury generally results from too long submergence of the fruit in the acid soln., or to the accumulation of too much acid in the rinsing water. The second type of injury occurs when fruit that has been rinsed in acid-contg. rinsing water is left for some time in the boxes. The skin injury occurs where the fruit touches either the contaminated wood-wool or the boards of the box. Some varieties of pears could withstand submergence in 1% HCl soln. for 5 min. at 70° F. without injury to the skin, while other varieties could not be submerged for more than 1 min. without injury. Varieties of pears growing inland in hot, dry districts appeared to be more resistant to lenticel injury than those growing near the coast, and immature pears appeared to be more susceptible than fully developed ones.

K. D. JACOB

Clouding of olive brine. S. HENRY AYERS, H. A. BARNBY AND E. L. VOIGHT. Research Lab. Glass. Container Assoc., N. Y. *Glass Container* 7, No. 10, 5-38(1928).—One cause of clouding in green olive brine is the growth of *mycoderma* yeasts. These appear as white to gray surface flecks or flakes. The NaCl content cannot be increased to a point high enough to prevent growth without rendering the olives unpalatable. Growth may be prevented by reducing the O tension of the container either by hot packing and filling or vacuum sealing methods. A tight seal is essential. Upon opening a jar of green olives, thus readmitting O, the film yeast will again proliferate. The yeast was entirely destroyed by a heat treatment of 60° for 10 min. when the NaCl concn. of the brine was 8% or more. Pasteurization of bottled green olives is advocated. No change in flavor or texture due to the heat treatment was detected. C. R. F.

Cider making. F. DE CASTELLA. *J. Dept. Agr. Victoria* 26, 356-60(1928).—The small-scale *manuf.* of different varieties of cider is discussed.

K. D. JACOB

A comparative study of the effect of copra meal and dried shrimps as supplements in rations for laying hens. JOSE A. SERRANO. Univ. of the Philippines, Los Baños. *Philippine Agr.* 17, 95-104(1928).—Dried shrimp is much better than copra meal as a source of protein. The av. annual egg production and increase in weight per hen with the two feeds were 92.6 and 59.5 eggs and 248 g. and 156 g., resp.

A. L. M.

The crops of the Bombay Presidency: Their geography and statistics. G. R. AMBEKAR. Dept. Agr. Bombay, *Bull.* 146, 148 pp.(1928).—Chem. analyses of the grain, vegetable and forage crops of Bombay are given.

K. D. JACOB

The biology of green feed preservation. KURT TRAUTMAN. Agr. Hochschule, Weihenstephan. *Centr. Bakt. Parasitenk. II Abt.* 74, 1-13(1928).—The enzymes which cause lactic acid fermentation in ensilage are of bacterial origin exclusively. Green plants cannot of themselves produce lactic acid under anaerobic conditions. J. T. M.

Japanese honeydrip sorghum silage versus June corn silage for milk production. W. S. CUNNINGHAM AND J. R. REED. Ariz. Agr. Expt. Sta., *Bull.* 122, 142-55(1927).—Japanese honeydrip sorghum yielded 21.6-35.6 tons per acre or double that of June corn. Cows relished the sorghum silage more and the milk production was 91-96% as much as where corn silage was fed. Corn gave increased butter fat yields of 1.68-2.94% over the sorghum.

ed., revised. New York: Orange Judd Pub. Co.; London: Kegan Paul, Trench, Trubner & Co. 344 pp. Reviewed in *Expt. Sta. Record* 58, 870(1928).

WATSON, ELIZABETH C.: *The Story of Milk*. New York: Harper (City and Country Series). 37 pp. \$1.25.

Algae as food. ALBERT CARTIER and PAUL GLOESS. Fr. 633,696, Sept. 8, 1926. Marine algae, particularly brown algae belonging to the family of Laminariaceae, are made palatable by treatment with bases such as magnesia which form sol. compds. with the colloidal matter therein.

Neutralizing protein food materials, etc., with glutamic acid or its salts. MASAO FUJII. U. S. 1,680,865, Aug. 14. See Brit. 279,985 (*C. A.* 22, 3002).

Coating for the inner surface of receptacles for foods. HILLHOUSE BUEL (one-half to William P. Hammond). U. S. 1,680,934, Aug. 14. The inner surface of pulp milk bottles or other receptacles is treated with a soln. of ethyl acetylcellulose in acetone contg. a plasticizing agent of light oil such as white poppy seed oil which is free from objectionable taste or odor; the deposited material is subsequently fused on the coated surface. Antiseptics, gums, etc., also may be added.

Coloring foods. HARRY H. REPLOGLE (one-half to John Young). U. S. 1,678,648, July 31. "Amaranth 107" or other edible org. coloring substances for use in foods are dissolved in ethylene glycol.

Apparatus for processing foods in cans, etc. JOHN COYLE (to Continental Can Co.). U. S. 1,681,101, Aug. 14.

Absorbing deleterious gases from canned food products. THOMA M. RECTOR (to Rector-Tenney Co.). U. S. 1,679,543, Aug. 7. A strip of uncoated Fe or small mass of steel wool or the like is used within cans for taking up gases.

Centrifugal emulsifying apparatus. A. W. EMPSON. Brit. 282,466, June 26, 1926. An app. is described suitable for the treatment of milk and cream, manuf. of margarine, etc.

Baking and preserving bread and similar foods. JEAN MATTI. U. S. 1,680,898, Aug. 14. Bread or the like is baked in a mold such as a tin can which during baking is provided with a vent for the escape of vapors and after baking this vent is closed so as to preserve the product in a gas-tight package.

Bread-making. OTTO OECHSLER. Fr. 633,822, May 3, 1927. To reduce the amt. of flour used in bread-making, NH_4Cl is added to the dough, with or without other substances such as starch, salt or flour.

Starch conversion product for use in bread-making, etc. W. D. STRIN. Brit. 281,979, Sept. 28, 1926. In making bread, cakes, macaroni or the like, a starch conversion product such as described in Brit. 282,178 is used in the dough. A formula is given for a yeast-leavened dough. Brit. 282,178 specifies heating starch with HOAc. Glacial HOAc mixed with a small quantity of $(\text{NH}_4)_2\text{S}_2\text{O}_8$ or methylamine sulfate may be sprayed on powd. starch, followed by heating, or the starch may be treated with HOAc vapors such as those produced by heating acid Ca acetate.

Yeast stimulant for use in dough. THEODORE B. WAGNER. U. S. 1,680,827, Aug. 14. The dried solubles of corn steepwater are mixed with substances such as flour or starch.

Apparatus and method of treating wheat with currents of moist air. LOUIS E. SMITH (to International Milling Co.). U. S. 1,679,099, July 31. A conditioning treatment is described for increasing the acidity and vol. of sol. carbohydrates and decreasing the starch and dry gluten content.

Apparatus for pasteurizing and deodorizing cream. FREDERICK L. ARMITAGE. U. S. 1,680,720, Aug. 14.

Electrically controlled valves for pasteurizing apparatus, etc. H. L. HOLMEN. Brit. 282,394, Dec. 16, 1926.

Cooked potato chips. MEYER F. RUFFNER (to Potato Waffles Inc.). U. S. 1,676,160, July 3. Perforated slices of potato of lattice-like form and about 0.125 in. thick are immersed in water at a temp. of about 17° for about 2.5 hrs., dried at atm. temp. for about a half hr., cooked for about 8-11 min. at a temp. not materially above 205° in a mixt. of about equal quantities of corn oil and cottonseed oil free from any material amt. of stearin and contg. about 1% of tallow, and the cooked product is then dried at an elevated temp. It is suitable for preserving in crisp condition for some time before use.

Treating fish for food. DAVID D. PREBBLES. U. S. 1,677,364, July 17. Fresh fish after being cleaned and washed is perforated and heated to dry off the wash water

and partially dry and harden the skin, then subjected to a broiling action which effects shrinkage, further sets the skin and partially renders the oil, and then cooled.

Refrigerating and preserving fish, meat or other foods. PAUL W. PETERSEN. U. S. 1,681,009, Aug. 14. Foods such as fish or meat are washed in a soln. contg. a germicidal agent such as NaOCl , frozen with the soln. remaining on the surface of the material, and then coated with ice.

Preserving moist comminuted coconut or other foods. DWIGHT TENNEY (to Rector-Tenney Co.). U. S. 1,679,386, Aug. 7. An app. is described for packing and preserving the material by subjecting it to a vacuum treatment to remove air and then sealing the material in dehydrated and sterilized air, alc. vapor or an inert gas such as N. The vacuum and gas or vapor treatments may be repeated.

Concentrated almond and milk sirup for use in foods or beverages. H. HOFER-MASSARD. Brit. 282,088, Dec. 10, 1926.

Apparatus for producing beverage extracts from holly leaves. STEPHEN M. HOYE. U. S. 1,679,525, Aug. 7.

Sterilizing vegetable juices. ANDRÉ KOEHLER. Fr. 633,878, May 4, 1927. To sterilize fermentable liquids such as fruit juice or wort, the microorganisms are centrifuged out, and a small quantity of SO_2 is then added.

Drying chamber for fruit. RENÉ DONZEAU. Fr. 634,201, Mar. 16, 1927.

Food for animals from fish waste, etc. CHEMISCHE FABRIK SCHLUTUP M. STERN. Brit. 282,068, Dec. 7, 1926. In leaching fish waste or the like contg. salt for removal of the salt, the water used for the extn. is treated to render it less capable of dissolving proteins, e. g., by addn. of protein or protein-pptg. substances such as salts of Fe, Al, Zn or Cr.

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

The Institute of Industrial Chemistry of the University of Bucharest. CONSTANTIN BELCOT. Univ. Bucharest. *Notiz. chim.-ind.* 3, 279(1928). (In French).—The events leading to the founding of the Institute are described (cf *Giorn. chim. ind. applicata* 5, 446(1922)). C. C. DAVIS

The recent development of the Russian chemical industry. ROMOLO ANGELONE. *Notiz. chim.-ind.* 3, 357, 359(1928).—A brief review, with economic data. C. C. D.

Impressions of the I. G. Plants of Europe. CHARLES F. MULLIN. *Am. Dye-stuff Rept.* 17, 499–501(1928). L. W. RIGGS

High-pressure industries in Germany. F. SCHULZ. *Pativa a Topeni* 9, 158–9 (1927).—S reviews the influence of the development of NH_3 synthesis upon other industries in which high pressure is essential in bringing about chem. reactions on a com. scale as the making of synthol, alcs., etc. FRANK MARESH

Sixty-fourth annual report on alkali, etc., works in England and Wales in 1927. T. LEWIS BAILEY. *Ann. Rept. Alkali Works 1928*, 3–35.—The results of the operation of the Alkali Regulation Act of 1906 during 1927 are outlined. They cover: alkali and Cu (wet processes), cement, smelting, H_2SO_4 (chamber and contact), chem. manure, $(\text{NH}_4)_2\text{SO}_4$ and gas house liquor, Cl, HCl, sulfide, $\text{Fe}(\text{NO}_3)_3$, Venetian red, bisulfite, tar and Zn works. In general, causes for complaint were quickly remedied. Tables show the no. of works registered, av. amts. of acid gases escaping and the amt. of NH_3 products produced in 1927. Methods of analysis are given for ammoniacal and spent liquors and notes on the estn. of polyhydric phenols. Analyses are included for condensates and effluents made at gas works using final acid catch. Results from 3 works using vertical retorts are tabulated, as are results of analysis of NH_3 liquors from low-temp. carbonization of coal where retorts are internally heated with addn. of steam. W. H. BOYNTON

Many new fields invaded by spray drying. EARL D. STEWART. *Chem. Met. Eng.* 35, 470–2(1928).—The process is briefly described together with its application to the drying of blood products, eggs, gelatin, soap, potato and banana flours, sugar products and inorg. salts. E. H.

Washing or dissolving various melts with water. S. S. VASSERMAN. *J. Chem. Ind. (Moscow)* 5, 404(1928).—It is not convenient to wash or dissolve melted substances such as Na_2S , BaS , etc. in Chanks' app. or any other app. at present used, since in these app. very large quantities of washing liquid are required which involve a large expense of steam for heating the liquid and also require much time. The same is true when washing crude *ultramarine* from Na_2SO_4 . V. recommends to operate as follows: Pieces

of the melt together with a small amount of water are heated with steam under pressure of 2-5 atm. in an autoclave. The mass is transformed into a paste which can easily be filtered in filter presses or vacuum filters. Even pieces of *Na silicate*, which dissolve with very great difficulty in water, can thus be brought into soln. within 5 hrs. A drawing of an autoclave particularly adapted for this purpose is given; this app. has been adopted by a Russian factory for solution of Na-silicate chunks. B. N.

Introfiers, or impregnation accelerators. MARC DARRIN. Mellon Institute. *Ind. Eng. Chem.* **20**, 801-4(1928).—An introfier is a substance that accelerates impregnation, by changing the fluidity and specific wetting properties of the impregnating material toward the substance being impregnated so as to increase the facility with which penetration is affected. A large number of introfiers are described which accelerate the impregnation of wood fiber by S. The mol. structure required by all S introfiers is a plurality of cyclic nuclei. Cl or OH substituted compds. may be used.

T. S. CARSWELL

The countercurrent use of decolorizing carbons. M. T. SANDERS. *Ind. Eng. Chem.* **20**, 791-4(1928).—The magnitude of savings possible through the use of stepwise countercurrent treatment is calcd. by means of a modified Freundlich's equation.

D. GORDON

The right of protest in cases of patents pending. GUSTAV SCHUCHARDT. *Chem.-Ztg.* **52**, 573-4(1928).—According to section 24 of the (German) patent law anyone can protest a prospective patent within 2 months of the publication of the claim in the official gazette. The applicant then receives notice of the objection and can reply. This process, introducing a third party to the proceedings, can be repeated and thus delay issuing the patent indefinitely; it works to the disadvantage of the applicant, especially in the case of an inventor working alone or on his own resources. On the other hand the protestant who "holds up" the patent does it practically without expense. The proposal is now made that the protestant be compelled to submit drawings, records of expts., testimony of witnesses, etc. in support of his objection and that the patent office then function as a court in deciding the questions involved. W. C. EBAUGH

Occupational intoxications due to chlorinated aromatic and aliphatic hydrocarbons, and their prevention. FLORET. *Zentr. Gewerbehyg. Unfallverh.* **14**, 372-7(1927); *Chimie et industrie* **19**, 1066-7(1928); cf. C. A. **22**, 2628.—A review. A. P.-C.

Controlling the temperature of exothermic chemical reactions. SELDEN CO. Brit. 282,559, Jan. 10, 1927. In reactions such as the production of phthalic anhydride by catalytic oxidation of $C_{10}H_8$ vapor with air, a compn. contg. Pb 3, Sn 3 and Hg 4 parts is maintained in heat-transferring relation with the reaction zone, this metal compn. having a b. p. of about 405° and serving to prevent too great rise of temp. in the reaction zone. An alloy of Cd 1 and Hg 3 parts (boiling about 400°) or other similar alloys also may be used.

Separating and recovering various gases from their mixtures. OSCAR L. BARNEBEY (to American Solvent Recovery Corp.). U. S. 1,680,840, Aug. 14. The gaseous

mixt. is passed under superatm. pressure through sepd. layers of solid adsorbent material such as activated C in an app. which is described. Numerous details are described.

Separating nitrogen oxides from other gases. SOC. L'AIR LIQUIDE, SOC. ANON. POUR L'ETUDE ET EXPLOITATION DES PROCÉDÉS G. CLAUDE. Brit. 281,675, Dec. 4, 1926. In some instances gases may be heated to bright redness to decomp. N oxides into N and O to purify the gas. Also to prevent contamination of gases such as coke-oven gases, with N oxides, when treated with H_2SO_4 ; any nitrosylsulfuric acid present in the H_2SO_4 may be decompd. by reducing agents such as gases evolved in distg. NH_3 liquor and contg. H_2S which also serves to ppt. As.

Baffle system apparatus for purifying gases. GRANT D. BRADSHAW (to Blaw-Knox Co.). U. S. 1,678,844, July 31.

Catalytic purification of gases. F. FISCHER. Brit. 282,634, Dec. 24, 1926. Gases such as water gas (which may be first freed from H_2S) are treated for the removal of S compds. other than H_2S by use of a catalyst of precious metal such as Au or Ag which convert the S compds. in the presence of H to H_2S without causing any other change in the gas. The gas is then further treated by a usual method for removing the H_2S formed. Silverized asbestos may be used at a temp. of 200–300°.

Adsorption of gases by solids. SOC. POUR L'EXPLOITATION DES PROCÉDÉS EDOUARD URBAIN. Fr. 634,424, Sep. 17, 1926. A rate of absorption of the carbon used is fixed and the speed of the gas is varied until this rate is reached but not passed.

Storing and transporting gases. PAUL N. LUCAS-GIRARDVILLE. U. S. 1,680,873, Aug. 14. CH_4 or other substance with a b. p. below 0° is stored in liquid or solid state in a heat-conducting vessel which is in heat-conducting contact with a liquid such as liquefied N exposed to atm. pressure and maintained in a heat-insulated vessel. The liquid used has a lower b. p. than the substance stored so that the slow and gradual evapn. of the liquid acts to maintain the stored material in its liquid or solid state.

Storing acetylene or other explosive gases. GAS ACCUMULATOR CO. (United Kingdom), Ltd. Brit. 281,718, Dec. 4, 1926. Porous fillings for storing gases consist of inorg. materials such as pumice or burnt clay, which have been soaked with solns. of inorg. salts such as $ZnCl_2$, NH_4 compds. and B compds. and silicic acid and then dried.

Oxidizing hydrogen sulfide in gases. I. G. FARBERIND. A. G. Brit. 282,508, Sept. 27, 1926. Illuminating gas after the usual ammonia washing step, or other industrial gas, of a humidity of about 80% of satn. or higher, is subjected to the action of active C, silica gel or other adsorbent. Cf. C. A. 22, 848.

Spray desiccation of various liquids. INDUSTRIAL WASTE PRODUCTS CORP. Brit. 282,480, Sept. 6, 1926. Waste sulfite liquors and sirups contg. sugar, molasses, malt exts., Cr tanning compns., glue or other materials are dried to obtain solid "glass-like" particles which are not hygroscopic by spraying into a current of heated gas the temp. of which, it is stated, may be as high as 540°.

Determining concentration of turbid suspensions. RALPH F. HALL (to John M. Hopwood). U. S. 1,681,339, Aug. 21. The suspension is dild. until a luminous object, when viewed through a predetd. thickness of the dild. suspension, has a definite standard of visibility. An app. is described.

Apparatus and liquid circulation system for recovery of suspended solids from liquids. WALTER L. REMICK. U. S. 1,678,788, July 31.

Dialyzing putrescible liquids. OLIVER M. URBAIN (to Travers Process Corp.). U. S. 1,680,349, Aug. 14. A putrescible liquid is maintained in a dialyzing tray floated in water in a zone free from O. An app. is described.

Agglomerating ores, coal or other powdered materials. A. UHLMANN. Brit. 282,104, Dec. 11, 1926. Powd. materials such as ore, coal, coke or ceramic materials are subjected to a high-frequency magnetic field to frit the particles together. The material may be preliminarily moistened with weak acid or an alk. soln. such as lime water.

Emulsions. WILFRED A. WHATMOUGH. Fr. 634,035, May 7, 1927. See Brit. 280,096 (C. A. 22, 3006).

Apparatus for the production of ice. GUSTAVE MANSIO. Fr. 634,319, May 13, 1927.

Can and air-pipe system for making artificial ice. JOSEPH A. MARTOCCELLO. U. S. 1,681,190, Aug. 21.

Apparatus for supplying dehumidified air to ice-making plants. IRVING C. JENNINGS. U. S. 1,680,381, Aug. 14.

Refrigerating system. FERNAN O. CONILL. U. S. 1,679,205, July 31.

Refrigerating systems employing liquid, vapor and gas. RANSON W. DAVENPORT (to Chicago Pneumatic Tool Co.). U. S. 1,680,453–4, Aug. 14.

Refrigerating system of the absorption type. CARL G. MUNTERS (to Electrolux Servel Corp.). U. S. 1,679,440, Aug. 7.

Refrigerating system of the absorption type. PLATEN-MUNTERS REFRIGERATING SYSTEM AKTIEBOLAG (to Electrolux, Ltd.). Brit. 281,710, Dec. 4, 1926.

Refrigerating system of the absorption type. A. EINSTEIN and L. SZILARD. Brit. 282,428, Dec. 16, 1926. MeBr and NH_3 may be used together in an app. which is described.

Refrigerating apparatus of the absorption type. SULZER FRÈRES SOC. ANON. Brit. 282,652, Dec. 24, 1926.

Reversing refrigerating system of the absorption type. SULZER FRÈRES SOC. ANON. Brit. 282,056, Dec. 8, 1926.

Reversing refrigerating system of the absorption type. C. G. MUNTERS (to Electrolux, Ltd.). Brit. 282,065, Dec. 8, 1926.

Refrigerating system of the compression type. FREDERICK E. LYNN. U. S. 1,679,729, Aug. 7.

Refrigerating apparatus of the compression type. G. ZWICKY. Brit. 282,031, Dec. 13, 1926.

Refrigerating apparatus of the compression type. FABRIQUE D'APPAREILS ÉLECTRIQUES F. SAUTER, SOC. ANON. Brit. 282,307, Dec. 14, 1926.

Insulating material. ISOLA-GES. m. b. H. Fr. 634,542, May 17, 1927. Minerals contg. Mg such as hornblende, dolomite or magnesite are melted and drawn into threads in a jet of vapor or compressed air.

Heat insulating material. HARVEY B. LINDSAY (to Dry Zero Corp.). U. S. 1,679,251, July 31. Insulation suitable for various purposes comprises kapok fibers in parallel arrangement.

Waterproof heat insulation. BENJAMIN F. WALLACE. U. S. 1,678,659, July 31. Insulation comprising porous MgCO_3 and fibrous asbestos is impregnated with a highly penetrative waterproof grease such as degreas which is water-repellent and which will readily float on water.

High-tension electric insulating bushing. QUARTZ ET SILICE. Brit. 281,734, Dec. 3, 1926. Structural features are specified of a device comprising a fused silica body supported by metal and enclosed in oil within a glass container.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Experimental studies on combined indole and fermentation methods for the identification of colon bacilli in drinking water. I. E. MINKEVICH. Military Medical Academy and State Inst. for Exptl. Medicine, Leningrad. *Centr. Bakt. Parasitenk. II Abt.* 73, 338-46(1928).—The most satisfactory fermentation medium is that of Bulir. It is tryptophan made by treating peptone for 3 days with pancreatic ext., plus 1% of mannitol. An indole test by the method of Gersbach is a useful supplement, i. e., a reddish violet color with Cl_2 water. Glucose inhibits indole formation. Maltose is unsatisfactory, as is a 46° incubation temp. CaCO_3 has no effect on the rate of indole formation.

JOHN T. MYERS

The effect of chlorination on drinking water. The use of α -naphthoflavone as indicator for free chlorine. M. HAHN, F. SCHÜTZ and SPIRO PAVLIDIS. Univ. Berlin. *Z. Hyg. Infektionskrankh.* 108, 439-73(1928).—A relationship exists between the oxidizability of a given sample of water and the necessary amt. of Cl_2 for destruction of the bacteria present. By titrating chlorinated water with α -naphthoflavone as indicator the point where an excess of Cl_2 is present can be easily detd., and thus a sufficiency maintained.

E. R. LONG

Principles of chlorine sterilization of drinking water. G. LUTZ. *Z. Hyg. Infektionskrankh.* 107, 585-91(1927).—The disinfecting action of chlorine is a Cl_2 effect. In the first few hrs. after chlorination the chlorine decreases only slightly, and the amt. of O_2 formed is small; yet a notable decrease in the no. of added bacteria occurs.

E. R. LONG

Use of liquified gases for the disinfection and eradication of infesting insects. H. PICK. *Chem. обзор* 3, 8-11, 40-1, 73-9(1928).—After a brief and comparative description of the phys., chem. and physiol. properties of liquid Cl_2 , SO_2 and HCN the application of the first gas for sterilization of water for drinking, bathing and sewage in Germany and N. America is described and its economy and advantages are stressed. Liquid SO_2 is used not only for destroying bacteria, but also for killing insects and other

organisms, e. g., in apartments and ships. For this purpose SO_2 becomes more and more replaced by HCN which can be applied in the liquified state as well. It is transported either in thick-walled steel vessels or, preferably, as "cyclone." This consists of liquid HCN absorbed in a porous granular material with addn. of stabilizing substances, and is transported in tin cans.

JAR. KUČERA

Boiler-scale formation and feed-water purification. HANNS FREYTAG. *Teer u. Bitumen* 26, 399-403 (1928).—A review.

F. S. GRANGER

Treatment and disposal of distillery slop by anaerobic digestion methods. S. L. NEAVE WITH A. M. BUSWELL. *Ind. Eng. Chem.* 20, 837-8 (1928).—Unless the slop is diluted it will not ferment. At diln. of 1-4 bacterial growth is slow because of the acidity of the slop. Excess CaCO_3 will improve the fermentation slightly. One part of slop to 9 of sewage ferments rapidly and completely. No offensive odor is obtained and 55% of the total solids of the slop are destroyed.

C. N. FREY

Report of an investigation of the pollution of Lake Michigan in the vicinity of South Chicago and the Calumet and Indiana Harbors. H. R. CROMBIE AND M. V. VELDER. U. S. Pub. Health Service. *Pub. Health Bull.* No. 170, 134 pp., 29 tables, 27 diagrams (1927).—Data were taken for 10 months, January and February being lacking. The Calumet district is primarily devoted to iron and steel and contains over 300,000 population. Much waste is discharged to Lake Michigan in spite of works designed to divert it to the Chicago Drainage Canal. Previous investigations are reviewed. Results are much influenced by wind and pptn. Vol. and kind of waste from 123 industrial plants are given. Of these 109 discharge practically no offensive industrial wastes. The remainder discharge over 2.5 m. g. d. of putrescible org. wastes and 8 m. g. d. of possibly taste-producing wastes. Sewage from 21,000 persons goes directly to Lake Michigan, that from 94,000 to the lake via the Indiana Harbor ship canal, that from 146,000 might reach the river by prolonged reversal of flow of the Calumet and Little Calumet Rivers. Dissolved color was absent but colored industrial wastes in suspension were frequently noted. Taste and odor were directly dependent on wind and location of the sampling station. On several occasions such tastes were strong at Chicago intakes at Dunne and 68th sts. Because of shallowness no important temp. differences were noted. Turbidity varies with direction and velocity of wind, depth, character of bottom and presence of added turbid wastes. Turbidity is in general higher with on-shore winds and decreases rapidly with distance from the shore. The turbidity is over the Treasury Department standard of 10 p. p. m. at 5 intakes located in this district from 38.6 to 9.5% of the time. Had samples been taken in January and February these figures would be higher. Samples taken at the cribs throughout the year agree substantially with these conclusions. Dissolved O_2 and B. O. D. indicate there is little discharge of the Calumet River into the lake as compared with the Indiana Harbor Ship Canal. The max. reversal of flow of the Calumet River into the lake was 1 or 2 days. Bacteriol. examn. shows a regular decrease with increasing distance from shore. Occasional pollution was found 8 miles offshore from the Calumet district. In general along the north shore gross pollution is not present while along the south shore to beyond the Indiana Harbor Canal gross pollution is usual. The water intakes of Hammond, Whiting and E. Chicago all lie in this zone of heavy pollution. At the 68th St. and Dunne cribs the mean agar count is 500-1000 per cc. and the *B. coli* index 10-100 per cc. The 4 mile crib is somewhat better. There is danger that all of these supplies may be subject to occasional pollution far in excess of that indicated. The supplies of Waukegan, Lake Forest, Hammond, Whiting and E. Chicago are grossly polluted by sanitary sewage, particularly the latter 3. That of Gary is questionable at times. The Chicago and Evanston supplies are suitable for use after chlorination.

FOSTER DEE SNELL

The toxicological analysis of air: diffusion of fumes and experiments at the Eiffel tower. E. KOHN-ABREST. *Chimie et industrie* 19, 979-88 (1928); 20, 29-32 (1928).—A discussion of the most reliable methods for detg. CO_2 , CO, other acids (HCl , SO_2 , etc.), H_2S , NH_3 , PH_3 , N oxides, O_3 , HCN, H and hydrocarbons, condensable vapors and compds. in a vesicular state. The importance of the pollution of the atm. of large cities, particularly the possible presence of CO due to motor traffic, is discussed. Expts. carried out at the Eiffel Tower showed that, if anything, the air in Paris is purer at ground level than at an altitude of 288 m., and that, contrary to results obtained in New York (where up to 0.04% CO was found in the atm. of busy thoroughfares), the air of Paris was found to be but very little polluted.

Purifying water. RALPH B. DERR (to National Aluminate Corp.). U. S. 1,680,506, Aug. 14. Water contg. less than about 50 parts per million $MgSO_4$ is mixed with a water-softening compd. such as lime and Na_2CO_3 and Na aluminate and the formation of a coagulant is activated by adding $MgSO_4$ or other material supplying Mg and SO_4 ions.

Purifying water. ARTHUR R. MOBERG (to National Aluminate Corp.). U. S. 1,679,777, Aug. 7. A relatively small quantity of Na aluminate and a relatively large quantity of Al sulfate are added to water, for purification and clarification.

Purifying water. W. PATERSON. Brit. 282,165, Sept. 17, 1926. To effect softening and sterilization, water is treated with excess of caustic lime, then carbonated and passed through a zeolite bed.

Apparatus for purifying water. J. F. JONES. Brit. 282,193, Nov. 1, 1926. A vessel contg. a treating reagent is placed in a by-pass between the inlet and outlet mains of a filter or base-exchanging treatment vessel, so that differences in pressure control the quantity of reagent supplied.

Apparatus for purifying water with lime water and sodium carbonate. JEAN-BAPTISTE GAIL and NOEL ADAM. U. S. 1,680,867, Aug. 14.

Filter for attachment to water faucets, etc. HERBERT H. CULVER. U. S. 1,680,323, Aug. 14.

Tank suitable for filtering and softening water. CHARLES P. EISENHAEUER (to The Duro Co.). U. S. 1,678,770, July 31. Structural features.

Apparatus for filtering water of irrigation ditches to remove moss, etc. ERNST L. BISHOP. U. S. 1,680,848, Aug. 14.

Apparatus for automatically determining and recording the quantity of gas present and temporary hardness of water. H. S. HATFIELD. Brit. 282,487, Sept. 20, 1926.

"Boiler composition" and disincrustant. HANS KARPLUS and WILHELM BACHMANN (to the Firm E. de Haen A.-G.). U. S. 1,679,037, July 31. Colloidal graphite is used with about 5 times its quantity of sulfite liquor from cellulose production.

Adding measured quantities of sulfuric acid or other reagents to water. GEORGE CAWLEY (to The Permutit Co.). U. S. 1,678,766, July 31. An app. is described in which a continuously flowing body of water is divided into major and minor portions; a proportioned quantity of reagent such as H_2SO_4 is added to the minor portion and it is then remixed with the major portion.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

Report on agriculture. J. A. VERRET. *Proc. Hawaiian Sugar Planters Assoc., 47th Ann. Meeting 1927*, 72-8(1928); cf. C. A. 21, 3282.—*Germination tests with cane seed* stored for several months in an atm. of CO_2 over $CaCl_2$ showed that seedlings from the stored seed are weaker than those from fresh seed and the mortality is higher. In expts. with several forms of *phosphate as fertilizer for sugar cane*, ground

raw rock phosphate gave in most cases almost as good results and in some cases better results than superphosphate and reverted phosphate. The indications are that raw rock phosphate can be used to a good advantage as a supplement to the sol. phosphates in building up the soil. Better results with molasses as a fertilizer for sugar cane are obtained if it is plowed in at least 6 weeks before planting the cane. When applied to young cane it should be placed in the middle of the row away from the cane stools in order to avoid burning and possible checking of growth.

K. D. JACOB

Tropical agriculture in Malaya, Ceylon and Java. W. ORMSBY-GORE. *India Rubber J.* 76, 94-9 (1928).—A review of recent research and developments and of present conditions.

C. C. DAVIS

Report of the work done by the agricultural chemist, Bengal, for the year 1926-27. M. CARBERY. *Dept. Agr. Bengal, Ann. Rept. for 1926-27*, 1927, 53-74; cf. *C. A.* 21, 3698.—Chem. analyses of a large no. of samples of diseased and healthy betel vines, and of soils on which they were grown, confirmed the previous conclusion that the *betel vine disease* is caused by some phys. condition of the soil and is not due to chem. action. Tables are given showing the *mech. analyses of soils from various districts in Bengal*; the *yield of juice and sugar from different varieties of sugar cane* and the *compn. of ash from different varieties of tobacco leaves*. Changes in the p_H of field soils were detd. during the period August 6 to October 11, but the results were inconclusive. In all cases the supernatant liquids from the soil exts. were more alk. than the residual muds. There was no definite indication that superphosphate, applied at the rate of 200 lb. per acre, has any effect on the p_H of the supernatant liquids or the residual muds of alk. soils. In expts. with castor and mustard cakes and manure as fertilizers for hemp the nitrate content of the soils reached a max. in 1 month after application of the fertilizer and then decreased to almost zero during the rainy season, August 1 to October 1, afterwards increasing to a second max. in March. Nitrates accumulated more rapidly in the surface soil than in the sub-soil during the dry season and were removed more rapidly from the surface soil during the wet season. The *compn. of the ash of juice from several varieties of sugar cane* varied as follows: SiO_2 0.65-3.53, P_2O_5 18.72-30.18, K_2O 22.27-32.44, Mn_2O_4 1.09-3.24, CaO 11.51-17.72, MgO 12.56-20.46%, and traces of Fe_2O_3 and Al_2O_3 . The *compn. of juice from date palms* was— P_2O_5 0.021-0.0399, KCl plus $NaCl$ 0.120-0.409, sucrose 11.66-17.27 and glucose 0.19-0.70 g. per 100 cc.

K. D. JACOB

Report on chemistry. G. R. STEWART. *Proc. Hawaiian Sugar Planters Assoc.*, 47th Ann. Meeting 1927, 134-51 (1928); cf. *C. A.* 21, 3415.—The following major constituents of H 109 sugar cane were present in the tops, trash, bagasse and mixed juice in 3 expts.— SiO_2 1527.6 to 2391.6; CaO 88.1 to 134.6; P_2O_5 104.8 to 142.9; K_2O 324.1 to 463.7; and N 174.1 to 203.2 lb. per acre. The cane juice contained the largest total quantities of P_2O_5 and K_2O , and the bagasse the smallest. The cane trash tended to have a higher total N content than the other portions and it also contained most of the SiO_2 and a larger portion of the CaO . With the exception of SiO_2 , the bagasse contained the smallest total quantities of the major inorg. constituents. Soils from small areas where H 109 cane suffered from acute root failure were found to contain more replaceable Mg than was present in adjoining fertile soils. Pot tests indicated that this excess of replaceable Mg may be partly responsible for root failure. The excess of replaceable Mg is probably due, partly, to the use of rather saline waters for irrigation and partly to the Mg freed by the weathering of soil minerals. Applications of mud press cake, molasses and org. matter gave notable reductions in nematode injury to sugar cane grown in pots. Under practically sterile conditions the more common soil-inhabiting nematodes did not multiply greatly and root destruction caused by them was small. It was difficult to obtain normal cane growth in practically sterile soil. Growth failure of Lahaina cane at Waipio could not be traced to the presence of harmful salts, toxic acidity, or deficiencies of plant nutrients in the soil, but comparative studies of the compn. of good and poor Lahaina canes showed a higher % of K_2O and a lower % of SiO_2 in the former. Spectroscopic examns. of the ash of both canes showed the presence of minute amts. of B and Pb in the good cane while these elements were almost entirely lacking in the poor cane. The oxidizing power of soils from good fields was found to be higher than that of soils from poor fields. Evidence was obtained indicating that this was due, in part, to the presence of Mn in the form of MnO_2 in larger quantities in the good soils. In the poor soils, Mn was either entirely absent or was present in very small quantities. Spectroscopic examn. of the ash of H 109 canes which were susceptible to eye spot disease and of those which were resistant to the disease showed that the latter contained small amts. of Zn while the susceptible canes were almost entirely free from this element. Soils upon which eye spot disease was prevalent were notably deficient in available P_2O_5 . Applications of S at the rate of 1000-

2000 lb. per acre gave effective control of *Pahala blight of sugar cane*. The larger applications appeared to be more efficacious in preventing the chlorotic condition. Such large quantities of S may be safely used on neutral or slightly alk. soils, but careful study of the change in reaction should be made before applying S to acid soils. Nitrous acid was a particularly valuable reagent for the preservation of cane stalks cut from the plant, where it was desired to develop roots on the stalk and then to feed the shoot with a nutrient soln. Aeration of the culture with a slow stream of O_2 was also beneficial. *Sealing pores in earthen reservoirs*.—Porous earthen reservoirs may be sealed by satg. the soil lining the reservoir with a sol. Mg or Na salt and washing out the displaced Ca with pure water. The Na- or Mg-satd. colloid then becomes highly dispersed and effectively seals up the pores of the soil lining. This method of treatment is successful only if comparatively pure water is to be stored in the reservoir after the surface is deflocculated. The pores will open up again if the water contains appreciable amts. of Ca.

K. D. J.

Report on entomology. O. H. SWEZEY. *Proc. Hawaiian Sugar Planters Assoc., 47th Ann. Meeting 1927*, 94–106(1928); cf. *C. A.* 21, 3249.—Expts. were carried out with molasses, mud press cake, org. matter, S, etc., for the control of *nematodes in sugar cane soils*. Molasses applied at the rate of 40 to 60 tons per acre produced excellent growth of cane roots with absence of cortex and stele rots, and with only moderate nematode infestation. Mud press cake at the rate of 40 tons per acre produced roots as good as those obtained with molasses, with no decay and only light nematode infestation. Org. matter at the rate of 70 tons per acre produced similar good effects, but the minute pit-making spring-tail insect, *Isotomodes*, increased in great numbers in this medium because of the abundance of its favorite food. CaO and P_2O_5 , in amts. equal to the application in mud press cake, produced good root growth which was accompanied by a great amt. of decay and by heavy nematode infestation. Uninoculated S at the rate of 5 tons per acre killed the plants or allowed only very poor growth, but there was no decay of the few roots present and nematodes were entirely absent. A proprietary S mixt., known as "sulfogerm," at the rate of 5 tons per acre gave good root growth and little decay, but with heavy nematode infestation. K. D. JACOB

The relation between the total chemical composition of the soil and the water extract. W. O. ROBINSON. *J. Am. Soc. Agron.* 20, 793–801(1928).—There is no obvious dependence of the compn. of the soln. upon the compn. of the soil except in the case of the more sol. anions and to a less degree of Ca and Na. The effect of soil minerals and soil colloids on the relation of the soln. to the soil is considered. Soil minerals are so complex and variable in different soils that little dependent relation can exist. On the other hand, the colloidal matter contains fewer combinations and some dependence of the compn. of the soln. upon the compn. of the colloid can be expected. This relation should apply to a soil chiefly made up of clay or of clay and pure quartz sand. E. F. S.

Alpine agronomy applied to the study of the formation of cultivated soils. LAURENT RIGOTARD. *Compt. rend.* 187, 249–51(1928).—A complete remodeling of the classification of soils is considered, based on a better knowledge of their progressive formation beginning with the various rocks composing the surface of the earth, and a more precise knowledge of the action of the various factors acting to create the cultivated soil among rocks. All of the classifications attempted appear to be made from a too particular point of view or else from studies made on the soils which are not representative of all cases which are produced in nature. None should therefore be adopted at this time as classic, and the problem should be taken up on a very general and extended basis.

E. F. SNYDER

Determination of soil reaction by means of Merck's universal indicator. H. WIESSMANN AND K. STEINFATT. *Forts. Landw.* 2, 488(1927).—Values of pH obtained by the Merck universal indicator agree closely with those detd. by Sørensen buffer solns. and by electrometric methods, although the limits of differentiation are much narrower in the latter processes.

B. C. A.

The mechanical analysis of soils by the tube sedimentation method. M. R. RAMASWAMI SIVAN. *Madras Agr. Dept. Yearbook 1926*, 29–39(1927).—Comparative mech. analyses were made on 4 soils by the Murray tube sedimentation and the usual beaker sedimentation methods. The Murray method gave results which compared favorably with the beaker method and an analysis could be completed in 24 hrs., while several days were sometimes required for the completion of an analysis by the beaker method. In expts. with 7 soils the av. time for deposition of various sized particles, by the Murray method, was—0.2–1.0 mm. 2 min. and 15 sec., 0.04–0.2 mm. 12 min. and 10 sec., 0.01–0.04 mm. 2 hr. and 10 min., and 0.01–0.002 mm. 24 hrs., while material in suspension after 24 hrs. was classed as clay.

K. D. JACOB

Alkali soil studies and methods of reclamation. P. S. BURGESS. Arizona Agr. Expt. Sta., Bull. 123, 157-81(1928).—White alkali soils contg. NaCl and Na_2SO_4 and black alkali soils contg. Na_2CO_3 and NaOH are unsuitable for crop production without reclamation. Black alkali is colored by the org. matter which it dissolves. White alkali has little or no solvent action on org. matter. Not only arid climates, but periodical excesses of moisture, causing a rise of ground water, are necessary conditions for alkali accumulations in surface soils. The salts differ greatly in their motility through moist soils. Nitrates and chlorides migrate with greatest speed, sulfates and bicarbonates next, while carbonates and hydroxides move very slowly. The freezing up or puddling which often occurs during reclamation of alkali soils is due to 2 factors. First, to the dispersing of the clay brought about by the strongly alk. reaction of the soil soln. This condition, in turn, is caused by the formation of small quantities of black alkali from the hydrolysis of Na zeolites. Second, to the filling-up of the very small openings or pores between the soil particles by pptd. $\text{Al}(\text{OH})_3$ when the alk. of the soil has been reduced by leaching to the proper point for the pptn. of this compd. The only economical method known whereby excess sol. salts may be removed from soils is by leaching, and for this to be successful, good drainage is the first essential. Reclamation measures were not permanent unless the water table was held below the reach of the root zone which, in fine-grained soils is from 8 to 10 ft. from the surface. A hard water is preferable to soft water and Na salts should not be present in excess of 600 p. p. m. Intermittent flooding and drying until leaching is practically complete, followed by an application of 1-2 tons of CaSO_4 per acre, is recommended to displace all the Na present in the soil zeolites. The gypsum opened up the soil by forming the more granular Ca zeolite and in addn. prevented the loss of essential plant food elements, particularly N and P. Several applications of gypsum followed each time by intermittent flooding and drying sometimes were necessary completely to free the soil from alkalis. A heavy application of some form of org. matter, preferably manure, is often feasible at the end of the leaching period. Upon decompn, CO_2 is evolved which unites with the last traces of black alkali to form Na_2CO_3 . Several alkali areas were successfully reclaimed. The use of rice as a cash crop during alkali soil reclamation was successfully carried out. C. R. FELLERS

The results of drainage and leaching trials at Peradeniya during 1927. A. W. R. JOACHIM. Trop. Agr. (Ceylon) 70, 302-11(1928).—Pots were filled with loam to a depth of 3 ft. and various fertilizer materials were worked into the surface at the rate of 60 lb. per acre of the fertilizing constituent. Two pots were treated with each fertilizer, of which one was planted with *Ilibiscus* and the other was uncropped. The drainage from the cropped and uncropped series averaged 38.6 and 65.1%, resp., of the 76.6 in. of rainfall. The total solids in the drainage from the uncropped pots was 2.1 times that from the other. Although N was added in the form of KNO_3 , NaNO_3 , $(\text{NH}_4)_2\text{SO}_4$, dried blood and cyanamide at the rate of 60 lb. per acre only, the equiv. of over 500 lb. per acre were recovered from each uncropped pot in the drainage water. The fallow pots lost 3.5 times as much nitrate as the planted ones. The control pots lost as much N as any to which nitrogenous fertilizer was added. These extremely high losses are attributed to the lack of compactness of the soil in the pots allowing good aeration, the soil temp. ranging from 24° to 30° throughout the period and the high amt. (7.8%) of org. matter in the soil stimulating nitrification to an unusual degree. CaO was recovered in the drainage from the cropped and uncropped pots at rates of approx. 200 and 600 lb., resp. Similar leaching of K_2O was equiv. to 40 and 70 lb. per acre. The losses of NH_3 averaged at a rate of about 1 lb. per acre. Only traces of P_2O_5 were obtained in the drainage from any of the pots. The pots receiving superphosphate gave drainage contg. less P_2O_5 than the controls. The H_2O draining from the control and KCl pots contained at the rate of 115.2 and 161.5 lb. Cl per acre per annum and this was the only case in which additions of sol. material noticeably increased the % of the same in the drainage over that in the controls. A. L. MEHRING

The effect of soil type and fertilization on the composition of the expressed sap of plants. M. M. MCCOOL AND M. D. WELDON. Mich. State Coll. J. Am. Soc. Agron. 20, 778-91(1928); cf. C. A. 21, 788.—Greenhouse samples of barley, sugar beets, field beans and red clover, and field samples of celery, cabbage, sugar beets, wheat and rye have been studied as to the content of nitrate N, P, K, Ca and Mg in the expressed juice. Field samples generally contain more of these nutrients than greenhouse samples. The % of each nutrient in the juice of the leaves is usually greater than in that of the stems, but in rainy weather K may be leached from the leaves to a greater extent than from the stems. Applications of the various mineral nutrients to the soil as fertilizer generally result in increased concns. of those elements in the juice of the crop. If one

element is decidedly a limiting factor, the slow growth of the plant appears to permit the accumulation of high concns. of other elements. Under these conditions, applications of the limiting element to the soil as fertilizer are likely to decrease the concns. of the other elements in the plants. E. F. SNYDER

The Neubauer method (for determining root-soluble nutrients in soils). F. MAJEWSKI. *Polish Agr. Forest Ann.* 17, 35(1927).—The Neubauer method does not compare favorably with that of Lemmermann (relative soly.) or with field trials, results obtained being, in general, the same as those arising from direct chem. analysis. Wheat is a more suitable plant than rye for use with the seedling method as it is more sensitive to changes in potash and phosphate concns. in the soil. B. C. A.

Plant composition as a guide to the availability of soil nutrients. ROBERT M. SALTER AND J. W. AMES. *Ohio Agr. Expt. Sta. J. Am. Soc. Agron.* 20, 808-36(1928).—In general the rates at which common crop plants take up N, P and K bear no const. relation to the rate at which the plant increases in dry wt., nutrient absorption being commonly more rapid during the early stages of growth and slower during the latter stages than the total growth rate. On the whole the Neubauer seedling method does not offer any advantages over the strictly chem. methods for exchange K or that sol. in dil. acids. The Neubauer test has little, if any, value as an indicator of P needs of the soil. From the data on corn S. and A. do not consider the stalk tests for either K or N requirements as sufficiently reliable to warrant their practical use under Ohio conditions. Forty-six references are given. E. F. SNYDER

Relation between water and potash in plant production. FRED W. MORSE. *J. Agr. Res.* 35, 939-46(1927).—Pot. expts. show that in soils with a low natural K soly. millet and soy beans obtain their supplies of K in direct proportion to the supplies of H_2O . When K is added together with other fertilizers millet is nearly indifferent to varied amts. of H_2O . For testing the availability of K in a soil millet appears to be a better crop than soy beans because the millet is less affected by variations in the water supply. The results are in accord with the law of the minimum. M. S. ANDERSON

Relationship between the sodium chloride content of soils and plant growth. TACKE. *Abhandl. Naturwiss. Vereins* 26, 503-27(1927).—The NaCl content of subsoils is more nearly const. than that of surface soils liable to flooding with saline river water. Variations in plant growth are more closely correlated with the salt content of subsoils than of surface soils. In general, the salt content and natural flora of soils are closely related, and variations in the former bring about periodic changes in the nature of the latter. B. C. A.

The agronomic application of a microbiological test. S. WINOGRADSKY. *Compt. rend.* 187, 161-5(1928).—A microbiological method for detg. the lime and P requirements of soils. E. F. SNYDER

Principal observations on nitrogen fixation by microorganisms. AUGUST RIPPPEL AND HANS POSCHENRIEDER. *J. Landw.* 76, 101-12(1928).—The principal considerations about the active relations of the N combinations, which take their origin from the large carbohydrate supply of the leguminous nodules in the form of starch and the disappearance of this starch in the hunger condition, make it probable, that the N fixation by microorganisms does not proceed so economically as might appear, if one takes into consideration the facts of the exothermic course of the NH_3 formation from elementary N and H. Contrary views have not considered that the necessary H can originate only in the limits of the conversion of org. substances, so that the N fixation can be considered only in this connection. E. F. SNYDER

Soil inoculation with "Nitrofer" (mixed cultures of Azotobacter). FR. ZUCKER. *Univ. Leipzig. Centr. Bakt. Parasitenk. II Abt.* 74, 208-13(1928).—It is effective in increasing N fixation. JOHN T. MYERS

The effect of soil amebae on the growth and development of Azotobacter chroococcum in sterile soil. THAIS-FEODROVA-VINOGRADOVA. *State Univ., Leningrad. Centr. Bakt. Parasitenk. II Abt.* 74, 14-22(1928).—*Azotobacter* in sterile soil is stimulated by amebae. Mannitol (1%) favors the development of amebae and hence of *Azotobacter*. There is a good bibliography. JOHN T. MYERS

The fig industry in Asia Minor. G. S. CHEEMA. *Dept. Agr. Bombay, Bull.* 131, 7 pp.(1927).—Analyses of the fine portions of soils from fig gardens at Nazilli, Meandre Valley, Asia Minor, gave— H_2O 0.22 to 0.28, org. matter 2.56 to 2.80, N 0.04 to 0.06, $CaCO_3$ 0.60 and P_2O_5 0.28%. The soils contained 26.90 to 38.99% of stones. In general, the fig soils are very rich loams contg. considerable humus. K. D. JACOB

Estimation of potash in soils and fertilizers. A quick method in the technique. M. R. RAMASWAMI SIVAN AND M. RAJAGOPALA AYYAR. *Madras Agr. Dept. Yearbook* 1926, 1-6(1927).—A HCl ext. of the ignited soil or fertilizer is prepd. in the usual man-

ner. An aliquot is evapd. to dryness and carefully ignited at a low temp. to avoid volatilization of KCl, and to convert chlorides of Fe, Al, and Mg into insol. oxides. The residue is extd. with boiling H_2O and sulfates are pptd. with $BaCl_2$. Ca and excess Ba are pptd. with Na_2CO_3 , the total vol. of soln. not exceeding 100 cc., and the ppt. is settled by centrifuging for 3 min. The clear filtrate obtained by decantation through a dry double filter contains only NaCl and KCl. Small aliquots of the filtrate are acidified with HCl and the K is pptd. as K_2PtCl_6 or $KClO_4$. A detn. can be made in 2 hrs. with a min. use of reagents. Several tables of results show that the method gives excellent results in the presence of Fe, Al, Ca, Mg, sol. SiO_2 and H_3PO_4 . K. D. J.

Some effects of fertilizers on the nature of the soil solution with special reference to phosphorus. C. H. SPURWAY. Mich. State Coll. *J. Am. Soc. Agron.* 20, 802-7 (1928).—In general a rough correlation exists between test results and quantity of fertilizer applied. Because of the intervention of certain modifying factors, one cannot expect to find a direct correlation between test results and quantity of P added to the soil. As a general observation soils showing 0.5 p. p. m. or less of sol. P respond to P fertilization. On soils showing 2.0 p. p. m. or more, the profitable use of P fertilizer is doubtful, except perhaps in intensive farming systems where the other nutrient elements are supplied in abundance. E. F. SNYDER

Annual report of the 1st economic botanist, Bengal, for the year 1926-27. G. P. HECTOR. Dept. Agr. Bengal. *Ann. Rept. for 1926-27, 1927, 35-8*; cf. *C. A. A.* 21, 3698-7 (1928).—Application of phosphate fertilizers tended to reduce the *transpiration ratio of aus paddy*. There was a distinct indication that the *osmotic pressures of the cell-saps of varieties of highland aus paddies* were higher than those of transplanted and of deep-water aman paddies, but there was no appreciable difference in the osmotic pressures of the cell saps of early and late varieties of aus paddy, and also between transplanted and deep-water aman paddies. In expts. on the *storage of potatoes*, untreated potatoes spread on racks kept better than those stored in bags, and also better than those treated with 1:1000 $HgCl_2$ solns., followed by fumigation with gasoline and loose storage in bags. K. D. JACOB

Some relations of green manure to the nitrogen of a soil. T. L. LYON AND B. D. WILSON. Cornell Agr. Expt. Sta. *Memoir* 115, 1-29 (1928).—Green-manure crops consisting of legumes, non-legumes and combinations of the two were grown repeatedly as cover crops on the same soil for a period of 10 years. The effect on the accumulation of nitrate N and on the gain or loss of total N was studied. The plants used were hairy vetch, field peas, rye, oats and buckwheat, in addn. to which grass sod was maintained continuously on certain plats throughout the 10 years. The crops, except the grass, were plowed under in late fall or early spring, and the land was kept cultivated until the middle of July when the crops were replanted. The greatest accumulation of nitrates during the fallow period was in the soil in which vetch was plowed under. The order of effectiveness of the other crops in this respect was rye, peas, oats, buckwheat. Conclusion: Not all legumes are more effective than non-legumes in producing a high content of nitrate N during the main part of the growing season. The advantage lay with those crops which reached less advanced stages of growth before being plowed under, even when the quantity of the crop above ground was less than that of the more rapidly maturing crops. Liming the soil increased the accumulation of nitrate N. The effect of the liming on the nitrate N content of the soil was more pronounced in the rye plats than in the vetch and the oat plats. The soil of all of the plats planted annually to cover crops lost more or less total N during the 11 years intervening between the taking of samples for detn. of that constituent. Vetch plats lost practically no N; peas, which as a legume might be expected to conserve soil N, were not so effective in this respect as was rye. The plats continually in grass gained 415 lb. of N to the acre. There was a close correlation between the nitrate N accumulation in the plats planted to the various cover crops and the loss of total N in the soil of these plats. The loss of total N was, without exception, in inverse order to the nitrate N content of the soil during the period when nitrates were highest. On the other hand, there was a less definite relation between the % of total N in the soil and nitrate N accumulation. The form in which this N was lost is not apparent, but it would appear to be protected from loss other than in drainage when in the form of nitrate, since the plats having a high nitrate content each year were the ones that lost the least N. Since the N lost is the part most readily available to plants, and since the amts. lost are often large, there may result a serious curtailment of fertility. The methods of mitigating the loss suggested by this expt. are (1) laying the soil down to grass for a period of years, and (2) the culture of those legumes which are most active in fixing N, among which is vetch but not field peas. C. R. FELLERS

Mathematical interpretation of experimental results (obtained with fertilizers for sugar cane.) Y. KUTSUNAI. *Proc. Hawaiian Sugar Planters Assoc., 47th Ann. Meeting 1927*, 171-5(1928).—The theoretical yield curves for sugar cane fertilized with varying quantities of K_2O but receiving const. amts. of N and P_2O_5 were calcd. from Spillman's formula, $Y = M - AR^x$, where Y is the yield when x units of fertilizer are used, M is a const. equal to the theoretical max. yield due to the combined effect of unlimited amt. of fertilizer and the soil fertility, A is a const. representing the theoretical max. yield due to unlimited amt. of fertilizer only but not including the natural fertility of the soil, and R is the ratio between the increment due to $x + 1$ units of fertilizer and that due to x units of fertilizer. This ratio is supposed to be const. for any given expt. and smaller than unity. M , A and R are evaluated from actual exptl. data. Cane yields calcd. by this formula approximated closely those actually obtained when K_2O was used at the rate of 60 to 240 lb. per acre, the actual yield differing from the calcd. yield by -0.27 to $+0.76$ tons per acre.

K. D. JACOB

The effect of fertilizing and surface tillage on the retention of moisture in the soil at the Kasaragod Experiment Station. K. GOVINDAN NAYAR. Madras Agr. Dept., *Yearbook 1926*, 80-5(1927).—Uncultivated plots retained much less moisture than cultivated ones. In the latter case, plots receiving green manures and cattle manure retained more moisture than the corresponding unmanured plots. In general, the application of mineral fertilizer, composed of $(NH_4)_2SO_4$, K_2SO_4 , and superphosphate, appeared to decrease the H_2O -holding power of the soil as compared with the soil in unfertilized plots. This effect was not due to any great differences in the phys. compn. of the soils in the 2 plots.

K. D. JACOB

The relative nitrifiability of different nitrogenous organic manures in certain soils of the Central Farm, Coimbatore. K. S. VISWANATHA AYYAR. Madras Agr. Dept., *Yearbook 1926*, 85-91(1927).—Pungam cake (*Pongamia glabra*), groundnut cake (*Arachis hypogea*), castor cake (*Ricinus communis*), horn meal, fish guano, and ganja cake (*Cannabis indica*), were used in nitrification expts. on a black cotton soil and a red garden soil. With the black cotton soil the % nitrification in 6 weeks was pungam cake 80, groundnut cake 100, castor cake 90, horn meal 12.5, fish guano 50, and ganja cake 50, while, in the same order, the % nitrification in 6 weeks in the red garden soil was 64, 84, 80, 84, 27 and 90. The cause of the high nitrification of horn meal and ganja cake in the red soil was not detd. $CaCO_3$ had no effect on nitrification in these soils. Data are given on the nitrite and NH_3 formation from the fertilizers at various periods after application.

K. D. JACOB

A note on the relative availability of the nitrogen of oil cakes as indicated by pot-culture studies. S. KASINATHA AYYAR. Madras Agr. Dept., *Yearbook 1926*, 92-5(1927); cf. preceding abstr.—Pot expts. with ragi were carried out with groundnut castor, hoongay and ganja cakes, steamed horn meal, and $(NH_4)_2SO_4$ on a brown loam garden soil contg. N 0.036%, total P_2O_5 0.069%, and available P_2O_5 0.011%, 100 mg. of N being used in each case. With N fertilizers alone the increases in yield of grain were in the following order—groundnut, hoongay, steamed horn meal, castor, $(NH_4)_2SO_4$ and ganja cake, while with N fertilizers plus superphosphate the yield of grain was in the following order—steamed horn meal, groundnut, castor, ganja cake, $(NH_4)_2SO_4$ and hoongay. Expts. on certain soils of the Central Farm and at Koilpatti showed that superphosphate when applied alone considerably depressed the yield of grain as compared with the yield from unfertilized soil, although the soil was not rich in available P_2O_5 . Favorable increases in yields of both grain and straw were obtained when N fertilizers were used in connection with superphosphate. The investigations are being continued.

K. D. JACOB

Liming and fertilizing of pasture at Winton Experimental Farm. R. MCGILLIVRAY. *New Zealand J. Agr.* 36, 96-8(1928); cf. C. A. 21, 3247.—In a 3-year comparative expt. with basic slag and Nauru ground raw rock phosphate as fertilizers for pastures, the growth of clover and the total yield of hay were decidedly lower on the plots fertilized with ground rock phosphate during the first 2 years, but ground rock phosphate gave as good results as basic slag in both respects during the third year.

K. D. JACOB

Artificial farmyard manure. M. CARBERY AND R. S. FINLOW. *Agr. J. India* 23, 80-5(1928).—Expts. were carried out on the manuf. of artificial manure from sugar cane trash, water, hyacinth, weeds and litter, dried teak leaves, etc. Satisfactory decompn. of all these materials was obtained in 3 to 4 months and the final products approximated the compn. of cow manure. Urea, diluted cattle urine, and cow manure and water gave the best results as promoters of cellulose decompn. NH_4 acetate also gave good results and NH_4 phosphate was an efficient substitute for $(NH_4)_2SO_4$ plus bone

meal. In field tests composts made with liquid manure gave slightly better results than ordinary cow manure, but NH_4 acetate composts gave lower results. K. D. J.

Davison Chemical Company exemplifies stability in fertilizer industry. ANON. *Fertilizer Green Book* 9, No. 8, 11-6(1928).—This is an illustrated description of the superphosphate and H_2SO_4 plants of the Davison Chem. Co., Baltimore, Md. MgSiF_6 and Na_2SiF_6 are produced from the F-bearing gases and vapors resulting from the treatment of phosphate rock with H_2SO_4 for the manuf. of superphosphate. A Pt-impregnated SiO_2 -gel contact mass is used as a catalyst in the contact H_2SO_4 plant.

K. D. JACOB

Superphosphate industry in Japan. KATSUMOTO ATSUKI. *J. Soc. Chem. Ind. (Japan)* 31, 109-10B(1928).—A review.

K. K.

Influence of various potash salts on the yield and starch content of potatoes. O. NOLTE AND R. LEONHARDT. *Mitt. deut. Landw.-Ges.* 1927, 689.—Confirming earlier observations that K salts other than sulfates tend to reduce the starch content of potatoes if applied late in the season, "Patent Kali" (mixed sulfates of K and Mg) produced a higher yield of tubers of higher starch content than "40% potash salts" in field trials.

B. C. A.

Important nitrogen losses during the fermentation and humification of highly nitrogenous plants. I. Lucerne. J. ZOLCINSKI. *Rocz. Nauk Poln. i Lesnych* 17, 349-77(1927).—During the humification of lucerne (in flower) as much as 40% of its total N is lost in 10 days and 60% in 100 days. Of this loss, approx. one half is as NH_3 and the balance as elementary N. The loss is minimized by leaving undisturbed and avoiding destruction of the covering layer of fungus mycelium. The considerable losses of N may to a large extent be attributed to physico-chem. processes. It is suggested that plants of moderate N content build up protein matter differing in constitution from that of legumes, and characterized by the presence of NH_2 and OH groups in the *meta*-position (*i. e.*, the least oxidizable position), and contain also more aliphatic groupings which are quite unoxidizable. There is practically no loss of N during the humification of plant tissue of moderate N content. **II. Red clover.** J. ZOLCINSKI AND A. MUSIEROWICZ. *Ibid* 377-96.—Red clover loses 28% of its total N during humification, largely as free N. The formation of nitrite or nitrate during the process was not observed. The C/N ratio of the fermenting mass approaches that of soil humus. The total P in the humified material does not vary. Temp. and time govern the extent of the humification process. The combination between chalk and humic acids is accelerated by a rise of temp. Leguminous plants serve as an excellent source of humus substances. Sufficient lime supplies are necessary to complete the humification process, which is very largely a phys. and chem. as well as a biol. one.

B. C. A.

The relationship between fertilizing and callus formation in tea. P. A. KEILLER. *Trop. Agr. (Ceylon)* 70, 288-301(1928).—The theory is advanced that inability of tea bushes to grow callus over wounds made in pruning is due to carbohydrate starvation resulting from continued plucking and pruning. Specimens of wood which contained starch in all tissues before pruning showed a total disappearance of starch from all tissues except in a thin band immediately below the cut surface 4 days after pruning. When tea is fertilized with readily available materials at pruning, the wounds heal very well.

A. L. MEHRING

Report of the tobacco substation 1927. Conn. Agr. Expt. Sta., *Tobacco Sta. Bull.* 10, 17T-82T, March, 1928.—**Influence of some fertilizer ingredients on the burn of tobacco.** P. J. ANDERSON, N. T. NELSON AND T. R. SWANBACK. *Ibid* 17T-34T.— $(\text{NH}_4)_2\text{SO}_4$ seriously lowered the fire-holding capacity both when tested by the strip test and when the cigar test was used. Dark muddy ash, uneven burn and coaling also characterized the cigar test. The fire-holding capacity was lowered by large quantities of dry ground fish in the mixt., but not so much as by $(\text{NH}_4)_2\text{SO}_4$. Tankage had no pronounced effect. Results with NaNO_3 were not entirely conclusive but did not indicate serious, if any, impairment of burn. Urea did not affect the fire-holding capacity but increased the whiteness of ash. Large quantities of P lowered the fire-holding capacity on the strip test but made no difference in the cigar test. KCl almost destroys the fire-holding capacity. K Mg sulfate lowered the fire-holding capacity when compared with high-grade sulfate. With KNO_3 , K_2CO_3 and K_2SO_4 the differences in fire-holding capacity were not large, but 2 yrs.' results ranked carbonate first, nitrate second and sulfate third. Ash characters were in the same order. Lime in large amt. reduced the fire-holding capacity when tested on the leaf. On the cigar, however, the fire-holding capacity was good. From the standpoint of whiteness of ash, closeness and evenness of burn, the cigars from the lime plots ranked highest. **Chemical analysis of tobacco from the nitrogen plots.** E. M. BAILEY AND P. J. ANDERSON. *Ibid* 35T-

50T.—Comparing the effects of fertilizer formulas in which cottonseed meal, castor pomace, NaNO_3 , $(\text{NH}_4)_2\text{SO}_4$, dry ground fish and tankage were used in combinations previously described, the results are: Different sources of fertilizer N have not substantially affected the quantity of total N, "ammonia" N, nitrate N or nicotine in the leaf, nor the ratios between them. The percentages of total N, "ammonia" N and nicotine N are invariably higher in the upper than in the lower leaves. Nitrate is more abundant in the lower leaves. The different fertilizer treatments have not affected appreciably the % of total ash, sol. silica, Fe, Ca, Mg, P, or K in the leaf. Increased percentages of Mn, S, and, to a less degree, alumina in the leaves were found in those plots treated with $(\text{NH}_4)_2\text{SO}_4$. This correlated with a more acid soil reaction and a poorer burn of the tobacco. The lower leaves of the plants (seconds and lights) have higher percentages of total (crude) ash, potash and Ca than the upper leaves. The upper leaves (darks) have higher percentages of P, N and Cl than the lower leaves. **The effect of some nitrogenous fertilizers on soil reaction.** M. F. MORGAN AND P. J. ANDERSON. *Ibid* 51T-4T.— $(\text{NH}_4)_2\text{SO}_4$ has had the strongest influence in changing the soil reaction, consistently making the soil more acid. NaNO_3 has just as consistently made it less acid but its influence in this direction is not quite so marked as the influence of sulfate toward acidity. Cottonseed meal has not made any appreciable change in reaction. Dry ground fish and tankage have had a very slight tendency to make the soil more acid. Urea produces a slightly more acid condition after the initial period of rapid NH_3 formation is concluded. One yr.'s experience with $\text{Ca}(\text{NO}_3)_2$ showed no appreciable difference from the check plots. Plots treated with KNO_3 for 3 yrs. at the rate of 267 lb. per A. (43% K_2O) show no significant change in reaction during that time. **Synthetic urea as a source of nitrogen.** *Ibid* 55T-6T.—The purpose of this expt. was to see whether urea can be used to replace, partly or entirely, the original ammoniates in the fertilizer mixt. It is shown that the av. yield during 3 yrs. is so nearly the same that the differences are not significant. **Fractional application series.** *Ibid* 57T-60T.—No advantage is gained by making several applications as compared with a single original application of the same quantity and kind of fertilizer. Where high yields are desired there seems to be no evidence in favor of fractional application. **Single sources of nitrogen.** *Ibid* 60T-2T.—An expt. to det. the effect of single sources of N. It seems that the response of a plant to particular nitrogenous fertilizers may depend largely on the seasonal factors of rainfall and temp. **Manure as a supplement to commercial fertilizer.** *Ibid* 62T-6T.—Results for the first yr. show some advantage from the use of manure. Stable manure and "Adco" manure used as a supplement have been about equally efficient in increasing the yield and improving the quality of tobacco in a dry and wet yr. **Organic matter in tobacco soils.** M. F. MORGAN. *Ibid* 66T-72T.—Forty-three fields in tobacco over 20 yrs. show almost exactly the same av. amt. of org. matter in the soil as the same no. of fields in tobacco for less than 7 yrs., in nearly all cases after a long period of practical non-use for agricultural purposes. **Progress report on the cover crop experiments.** *Ibid* 72T-5T.—For 1927 only all cover crops with the exception of timothy increased the yield. **Tobacco mosaic.** G. P. CLINTON AND FLORENCE A. MCCORMICK. *Ibid* 75T-82T.—The effect of this disease on the tobacco plant, its cause, known facts of mosaic and preventive measures are discussed. E. F. SNYDER

Report on pathology. H. ATHERTON LEE. *Proc. Hawaiian Sugar Planters Assoc., 47th Ann. Meeting* 1927, 109-20 (1928); cf. C. A. 21, 3414.—The toxin produced by the eye spot fungus was isolated, and shown to be inorg. in nature, apparently an inorg. nitrite. Applications of N fertilizers in the autumn months increased eye spot infection severely, while P_2O_5 and K_2O fertilizers slightly reduced the disease. N fertilizers should be applied to cane during the period of longest days of sunlight and least probability of rain. Increasing the interval between irrigation applications in the winter months to 30-45 days reduced eye spot infection considerably. S dusts were much more efficient when combined with oxidizing agents which produce more quickly the active pentathionic and other polythionic acids upon which S is dependent for its fungicidal and germicidal value. The development of varieties of cane resistant to the eye spot disease has given considerable promise. Applications of S to alk. soils for the control of root rot disease of sugar cane had no beneficial effect although the soil was rendered distinctly less alk., and variations in applications of P_2O_5 and K_2O fertilizers had no visible effect on the disease. The H 109 variety of cane was in general highly resistant to *Pythium* root rot. Exptl. results obtained thus far indicate that various fertilizer treatments have no effect in controlling the mosaic disease. Inoculation of healthy tissue with young, fresh gall material did not result in production of stem gall of sugar cane, but in one case definite gall was obtained by inoculation with NH_3 .

solns. With both NH_3 and sucrose solns. a rind reaction was produced with a striate appearance similar to that present when stem galls occur. This indicates that stem gall may result from the injection into the plant tissues of some org. compd., or NH_3 , by insects feeding on the plant. The investigations are being continued. Such factors as wind and strong sunlight, which will cause excessive transpiration by the leaves, seem to be the cause of *leaf burn of cane*. K. D. JACOB

Germination tests on millet seeds. G. N. RANGASWAMI AYYANGAR AND C. VIJAYARAGHAVAN. Madras Agr. Dept., *Yearbook 1926*, 14-20(1927).—Addn. of 1.5 g. naphthalene to tightly closed 8-oz. bottles of millet kept the seed free from insects and had no effect on germination when the seeds were stored for 2.5 years. Seed preserved in this way cannot be used as food because of the persistent naphthalene taste.

K. D. JACOB

Annual report of the fiber expert to the Government of Bengal, for the year 1926-27. K. McLEAN. Dept. Agr. Bengal. *Ann. Rept. for 1926-27*, 39-43(1927).— $(\text{NH}_4)_2\text{SO}_4$ gave a good increase in the yield of jute, but CaCN_2 was not effective. Expts. were made to det. the % of fiber to green plant in different varieties of jute. The plants were stripped of leaves and retted with a soln. contg. 0.05% NH_3 acetate and 0.05% KH_2PO_4 . The % of stripped plant on green wt. varied from 86 to 89 and the % of fiber on green wt. from 6.0 to 8.0. The % of stripped plant and of fiber was not const. for any one variety and the heavier plants gave a smaller % of fiber. As much as 7% of pure alc., on the dry wt., was obtained in expts. on the rain pods tree as a source of alc. K. D. J.

Studies in the shedding of mango flowers and fruits. I. P. V. WAGLE. Agr. Research Inst., Pusa. *Memoirs Dept. Agr. India, Botanical Series* 15, 219-49(1928).—Shedding of mango flowers and fruits could not be traced entirely to mildew and mango jassid hopper attacks. Whether pests and blight were present or not, spraying with Bordeaux mixt. and fish oil resin soap solns. increased the loss of unfertilized flowers but in some cases reduced the fall of flowers after fertilization. When mildew was present, spraying with Bordeaux mixt. resulted in a considerable increase in the % of ripe fruit, but spraying with fish oil soap soln. was distinctly harmful. In the presence of mango hoppers, spraying with fish oil soap soln. increased, in the flowers heads under examn., the yield of ripe fruit by 62%, while a combined spray of Bordeaux mixt. and fish oil soap soln. was not effective even against the hoppers. The investigations are being continued. K. D. JACOB

Cockroach destruction in buildings. B. B. FULTON. Ia. Agr. Expt. Sta., *Circ.* 112, 1-4(1928).— NaF used as a dry dust is particularly effective against cockroaches in dry places only. The use of $\text{Ca}(\text{CN})_2$ as a fumigant at the rate of 2.5 lb. per 1000 cu. ft. in damp basements gave excellent results. C. R. FELLERS

Clarification of waste tannery liquors and their utilization for agricultural purposes (HLAVINKA) 29. **Edible canna in the Waimea district of Hawaii** (RIPPERTON, GOFF) [as fertilizer] 12. **The agricultural and biochemistry building at the University of Minnesota** (GORTNER) 2. **Determination of organic C in soil** (DE NARDO) 7. **The microchemical determination of P_2O_5 as strychnine phosphomolybdate** (ANTONIANI, JONA) 7. **Injury to pears by HCl solution** (PETTEV) 12. **Injurious field rats of Lower Lind and their extermination** (WAGLE, MAHOMED) 18. **The action of Al, ferrous and ferric Fe and Mn in base-exchange reactions** (MAGISTAD) 6.

Fertilizer. F. G. LILJENROTH. *Brit.* 282,330, Dec. 14, 1926. Crude Ca phosphate is leached with HNO_3 or other acid, the Ca salt of which is sol., and CaSO_4 is pptd. by the simultaneous or subsequent addn. of a sol. sulfate, preferably $(\text{NH}_4)_2\text{SO}_4$; the soln. is filtered, neutralized (preferably with NH_3) and evapd. to form a fertilizer. The CaSO_4 may be treated with NH_3 and CO_2 to form $(\text{NH}_4)_2\text{SO}_4$ and CaCO_3 or may be heated to produce SO_2 for prepn. of H_2SO_4 and manuf. of alkali sulfate. K compds. such as KCl may be added to the fertilizer. Cf. C. A. 22, 2434.

Fertilizer. C. F. BOEHRINGER & SOHNE G.M.B.H. Fr. 634,588, Mar. 2, 1927. See *Brit.* 268,744 (C. A. 22, 1440).

Fertilizers. SYNTHETIC AMMONIA & NITRATES, LTD., AND A. E. MITCHELL. Brit. 282,463, June 19, 1926. Superphosphate and NH_4NO_3 are mixed with K_2SO_4 or other alkali metal sulfate.

Removing magnesium salts from fertilizers. FRANS G. LILJENROTH. Fr. 633,830, May 3, 1927. K salts are freed from Mg salts by dissolving in water and adding NH_3 and CO_2 in excess, the NH_3 being in excess of the CO_2 .

Fertilizers and insecticides. VITTORIO CASABURI. Fr. 632,516, Aug. 19, 1926. Addn. to 611,545. The alkali lye used in the parent case as an adhesive for insecticides or fertilizers is replaced by the vegetable substances called hemicelluloses prep'd. from carob beans.

Insecticide and fungicide. FRANCIS M. ROGERS and CLAUDE P. MCNEIL (to Standard Oil Co. of Ind.). U. S. 1,679,919, Aug. 7. A compn suitable for use in the form of an aq. emulsion on plants or seeds comprises a "mahogany soap" or other suitable salt of a sulfonic acid derived from mineral oil, an oil-dispersible Cu compd. such as the naphthenate or sulfonate and a mineral oil such as paraffin oil. Other substances also may be added.

Fungicides. I. G. FARDENIND. A.-G. Fr. 634,605, May 18, 1927. See Brit. 271,480 (C. A. 22, 1648).

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Acetylmethylcarbinol formation in the alcoholic fermentation of sugar. L. ELJON. Ned. tijdschr. hyg. microbiol. 1, 171-9(1926).—The appearance of AcCHMeOH as a product of the fermentation of sugar fixes the AcH , which can no longer act as H acceptor. Free H, however, is not evolved, but a complex reduction process takes place, the nature of which is under investigation. B. C. A.

Adulterated wines and Micko distillation. CARL BREBECK. Chem.-Ztg. 52, 377-9(1928).—Government regulations and the analyses of various wines are discussed. The procedure used in making the Micko distn. is described. The residue left after distn. is important in detg. the adulteration. The odor and the taste of the distillate serve as a means of identifying impurities. The Micko method is the only one giving an accurate knowledge of the character of the wine and the adulterants employed.

C. N. FREY

A volumetric method for the determination of carbon dioxide in beer. HARRY LUNDIN AND JOHN ELLBURG. Wochschr. Brau 45, 339-41, 349-52(1928).—The CO_2 in the beer is dissolved by NaOH and then measured in a Van Slyke app. after liberation with H_2SO_4 . A SCHULTZ

An antique refractometer for testing beer. H. W. VAN URK. Pharm. Weekblad 65, 758-61(1928).—Description of a simple refractometer constructed in 1847. Tests with EtOH and glycerol solns. showed the detn. of n to be accurate within 1 unit in the 3rd decimal. A. W. DOX

The influence of sodium chloride on the growth and metabolism of yeast. H. B. SPEAK, A. H. GEE AND J. M. LUCK. Univ. of Toronto. J. Bact. 15, 319-40(1928).—Wort contg. NaCl up to a concn. of 10% can be fermented by *S. cerevisiae*. The wt. of the yeast crop decreases with increase in salt concn. The lag phase of the fermentation period is progressively lengthened by increasing NaCl concn. The influence of NaCl on the max. rate of CO_2 production depends on the size of inoculum as well as salt concn.; small inoculum and low concn. are stimulating and large inoculum and high concn. depressing. When NaCl is added at some point during active fermentation, concns. up to 1.5% are stimulating but not immediately and above that depressing to the rate. The effect of NaCl is not on cell metabolism but on cell division. The N content of yeast crops from media contg. NaCl , and inoculated with 0.002 to 0.04 g. of yeast increases up to 6% NaCl , and from 6 to 10% is the same as the controls. When the inoculum is a total crop of yeast, 0.4 g., which ferments the medium with great rapidity and doubles in wt., the N figure changes qualitatively in a similar manner over the same range of salt concn. The quant. changes are much smaller. Yeast crops of this type exposed to the salted media for times equal to the length of normal fermentation do not show any greater changes in N content, indicating that the time factor is not important. This quant. difference is probably due to the different effects of NaCl on existing cells and those formed by division in the exptl. media. The ratio, sugar fermented; yeast crop, increases with NaCl concn. up to 5%. In higher concns. the crops have a gradually diminishing efficiency. This holds when the time factor for controls and salted

medium is const. and its significance is increased in the light of a gradual prolongation of the lag phase by these concns. of salt. The changes in efficiency parallel the N content. As the concn. of NaCl increases (up to 2%) the ratio, CO_2 : sugar utilized, rises gradually. In higher concns. the ratio gradually falls to considerably below the control figure. During a normal wort fermentation, this ratio rises, suggesting an accumulation of intermediates in the early stages.

JOHN T. MYERS

Advantage or disadvantage in drying barley. HERMANN KROFF. *Wochschr. Brau.* 45, 336-7(1928).—The drying of barley for malting is beneficial because of the improvement in germinating qualities and also because respiration losses in stored undried barley are greater than drying costs.

A. SCHULTZ

Barley proteins. I. The composition and quantitative estimation of barley proteins. L. R. BISHOP. *J. Inst. Brewing* 34, 101-18(1928).—Osborne (*J. Am. Chem. Soc.* 17, 539(1895)) found in barley an albumin, a globulin, a gliadin (hordein) and a glutelin, and subsequent work has not materially affected this classification of barley proteins. B. made a study of the conditions necessary for sepg. the proteins and evolved a method of sepn. Ext. 10 g. of finely ground barley with 70 cc. K_2SO_4 soln., p_H 5-6, 5 successive times and centrifuge each to sep. the extns. from the barley. Make up the resulting extracts to 500 cc and use 100 cc. for N detn. Buffer 200 cc. of the salt ext. with $N \text{ NaC}_2\text{H}_3\text{O}_2$ and $\text{HC}_2\text{H}_3\text{O}_2$ to p_H 4.6, heat to 82° for 20 sec. and det. in the ppt.; this represents the albumin N. For the non-protein N, titrate 70 cc. of the salt ext. with 0.1 $N \text{ CuSO}_4$ after adding 10 cc. of 0.1 $N \text{ NaOH}$, until the violet color changes to green. N detd. in the ppt. obtained by centrifuging represents non-protein N. To det. hordein mix the salt-extd. barley with 60 cc. of 70% EtOH in a tube closed with a rubber stopper and screwed tightly in a small brass app. Put the tube into a bath at 82° , shake at frequent intervals during a period of 30 sec., allow to cool a minute and centrifuge. Make 2 further extns. and make up the total exts. to 250 cc. Det. N on 100 cc. of the ext. Det the glutelin N by subtracting the sum of the salt and alc.-sol. N from the total N of the barley. To minimize bacterial action all extns. and detn. of N are carried through as quickly as possible. These detns. were carried out on a number of different barleys of from 1.2 to 2.3% total N and the glutelin in the barleys was found to remain const. at 36% of the total N. The hordein increased as the total N increased, rising from 26% in the 1.2% N barley to 40% of the total N in the 2.3% N barley. The salt-soluble N fell from 36% to 24% as the total N increased from 1.2% to 2.3%. B. therefore concludes that total N is a good measure of the quantities of individual proteins present, and there appears to be a balance between the various proteins which adjusts itself according to the total N present, which in turn is influenced by soil and season.

PETER J. F. WEBER

Malting barleys of 1927. JAMES STEWART. *J. Inst. Brewing* 34, 128-43(1928).—A summary of general characteristics of English barleys as to acreage, crop, quality and price. Some statistics regarding those barleys usually imported are also given.

PETER J. F. WEBER

Modern malt kilns. A. FERNBACH. *Pasteur Inst., Paris. J. Inst. Brewing* 34, 119-27(1928).—C. Winckler has proposed a single-floored kiln with direct heating and which uses a loading of green malt three to five feet deep. The hot gases coming into contact with the green malt give rise to a considerable evapn. and any tendency of the damp malt to increase in temp. is checked by the refrigeration due to evapn. The hot gases which are blown in through the green malt by a ventilator at a pressure of about 2 in. of water have a temp. of 70° to 80° during the whole process. The temp. of the gases leaving the malt rises to 24° in 2 hrs., remains const. at 24° for 6 hrs., then rises to 60° in 2.5 hrs. and finally reaches 70° to 75° . There is no turning of the malt at any time. Only 14 hrs. is necessary for kilning (as against 48 hrs. with usual kilns) and this results in no detrimental effects on the malt such as dark color or steely malt. Advantages of the Winckler kiln are small space, less height, lower fuel consumption and lower labor costs.

PETER J. F. WEBER

History and uses of vinegar. C. A. SMITH. *The Fleischmann Co., N. Y. Glass Container* 7, No. 10, 20-31(1928).—Vinegar manuf. is described together with a general discussion of properties, and uses. It is maintained that vinegar is a true food.

C. R. FELLERS

Analytical data on malt, apple, melon and spirit vinegar, on apple and pear wine, as also general information respecting the composition of grape wines. PAUL HASSACK. *Deut. Essigind.* 32, 266-8(1928).—Three different samples of malt vinegar had the resp. const.: d. 1.0143, 1.023, 1.020; total acid 4.25, 6.61, 5.50%; alc. vol. % 0.585, —, —; total ext. 2.27, 4.23, 2.75%; ash 0.22, 0.57, 0.44%; P_2O_5 0.073, 0.13, —%; N 1.08, —, —; sugar as glucose 0.79, —, —%; As and metals none; dextro rotation 200 mm.

tube —, 2.9, 1.7. Complete analysis of *cider vinegar*: d. 1.0177; total acid 5.21; non-volatile acid as lactic 0.18; alc. vol. % 0.35; glycerol 0.30; total ext. 2.40; reducible sugar as invert 0.47; volatile ester as EtOAc 0.060; sugar-free ext. 1.90; pentosans 0.16; formic acid 0.003%. Av. compn. of *grape must*: d. 1.040–1.124; total sugar in 100 cc. not under 7 g. nor over 28 g.; ash 0.2–0.55 g. per 100 cc.; P_2O_5 15–70 mg. Analysis of *vinegar* from a mash of *sugar cane molasses*: acid 4.66, total ext. 2.09, sugar-free ext. 1.73, reducible sugar 17.0, ash 32.4, P_2O_5 0.017%; *melon vinegar*: d. 1.0248, acid 4.25, alc. none, total ext. 4.85, ash 0.48%, color yellow (caramel); *spirit vinegar*: d. 0.008, acid 4.31, alc. 0.05, total ext. 0.18, sugar-free ext. 0.16, ash 0.016%. In addn. the paper contains analytical values (limits) for grape, true and malt port, pear wines, as also dry fermented apple wines. W. O. E.

NEHBEL, HARALD: Über den Bau und die Bedienung von Destillier- und Rektifizier-Apparaten für alkoholhalt. Maischen (Gewinnung u. Reinigung des Spiritus) nebst e. Anh. über Wasser-Destillier-Apparate. 2nd ed., revised and enlarged. Berlin: Maetzig & Co. 537 pp. Cloth, M. 24.

Fermentation. TREUHAND-GES. M.B.H., BARTMANN & Co. Fr. 634,119, May 10, 1927. Cereals, potatoes and like starch-contg. materials for the prepn. of alc., sugar, or malt are allowed to swell in a suitable medium till they become pasty and then are submitted to mechanical pressure.

Citric acid by fermentation JOSEF SZÜCS (to Montan- und Industrialwerke vorm. Joh. Dav. Starck). U. S. 1,679,186, July 21. Organisms which produce citric acid are cultivated on molasses at temps. of 15–30° and cultures are selected which are adapted for producing citric acid fermentation without producing oxalic acid, and the selected cultures are used for producing citric acid by fermentation of molasses.

Dihydroxyacetone. I. G. FARBENIND. A.-G. Brit. 282,347, Dec. 18, 1926. The process described in Brit. 269,950 (C. A. 22, 1433) is modified by the use of substances extd. from the waste products of malt such as brewer's grains as a nutrient medium for the bacteria employed for production of dihydroxyacetone from glycerol.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Thalleoquinine reaction. B. OLSZEWSKI. *Rocz. Farm.* 4, 119–30(1926).—Optimally, 1 mol. of quinine is treated with 4–8 atoms of Br for 15 sec. In the micro-reaction, the ppt. is dissolved in 30% AcOH, the acid removed by evapn., and the residue, after soln. in water, treated with 1 drop of dil. Br water. B. C. A.

Ethylene oxide as a fumigant. R. T. COTTON and R. C. ROARK. Bureau Chemistry. *Ind. Eng. Chem.* 20, 805(1928).—Ethylene oxide is highly toxic to insects, the relative toxicity of $CH_3O.CH_3$, CS_2 , and CCl_4 being 1:1.5:30, resp. For commercial

fumigation it should be used at the rate of 2 lb. per 1000 cu. ft. of space. It has no deleterious effect on foods, clothing, furniture, or metals. T. S. CARSWELL

Comparative tests with certain fumigants. L. F. HOYT. Larkin Co. *Ind. Eng. Chem.* 20, 835–7(1928).—Fumigation tests were made on different fumigants in an air-tight room. The following dosages in lb. per 1000 cu. ft. were found to give a 100% kill of all insects used: calcyanide, 0.5; chloropicrin, 0.8; trichloroethylene, 7.6; ethylene oxide, 2.0; lethane 23, 1.5; $ClCH_2CH_2Cl-CCl_4$ mixt., 14.0. Except for ethylene oxide, none of the fumigants had a deleterious effect on seed germination. T. S. CARSWELL

Nutmeg culture in the Dutch Indies since abolition of the monopoly. A. H. W. M. HERMANS. *Pharm. Weekblad* 65, 737–58(1928).—A description of the methods

employed in the cultivation, prepn. and marketing of both nuts and leaves, and data on the phys. consts. of the oil from numerous species of *Myristica*. A. W. DOX

The essential oil of *Podocarpus ferrugineus*. J. E. HOSKING and W. F. SHORT. Univ. College, Auckland, New Zealand. *Rec. trav. chim.* 47, 834-8 (1928).—From the leaves and terminal branches of *Podocarpus ferrugineus* (Miro-pine) the essential oil was extd. by steam distn., the yield being 0.14% from material collected during the spring and 0.09% from that collected during the autumn. The autumn oil showed the following constns: d_4^{25} 0.9602, n_D^{25} 1.4922, $[\alpha]_{5461}^{25}$ 32.97°. 276 g. were distd. and the following fractions collected: (1) 152-60° (745 mm.), 35.3%; (2) 110-70° (745 mm.) 1.6%; (3) 170-80° (745 mm.), 5.0%; (4) 104-25° (12 mm.), 6.3%; (5) 125-39° (12 mm.), 8.3%; (6) 139-46° (12 mm.), 1.1%; (7) 150-6° (12 mm.), 4.1%; (8) 149-52° (2 mm.), 21.8%; (9) 152-70° (2 mm.), 4.4%; (10) 140-70° (0.2 mm.), 0.7%; (11) a resinous residue, 5.4%. Refractionation of fractions 1 and 2 yielded 80 g. of a hydrocarbon, b_{783} 156-7° d_4^{15} 0.8620, n_D^{15} 1.4663, $[\alpha]_{5461}^{15}$ 47.48°, the identity of which with *d- α -pinene* was established by the prepn. of the *nitrosochloride*, m. 103°, the *nitrobenzylamine*, m. 122°, and the *semicarbazone of pinonic acid*, m. 201°, obtained by oxidation of the hydrocarbon. By redistn. of fraction 3, 8 g. *d-limonene* were obtained, b. 174-6°, n_D^{14} 1.4771, $[\alpha]_{5461}^{15}$ 38.42°. Its identity with *d-limonene* was established by means of the *tetrabromide*, m. 103°, some *dipentene tetrabromide*, m. 121°, being obtained during its purification. Fraction 4 on redistn. gave a small quantity of liquid with a cineole-like smell. The hydrocarbons present were destroyed with cold 5% $KMnO_4$, the remainder (3.6 g.) b_{714} 175.5-76°, n_D^{20} 1.4582. It was identified as *cineole* by the prepn. of the *iodole deriv.*, m. 112°. Systematic refractionation of fractions 5, 6, and 7 gave a hydrocarbon, $C_{15}H_{24}F_2$, b_{10} 129-31°, d_4^{15} 0.9193, n_D^{15} 1.5065, $[\alpha]_{5461}^{15}$ 11.68; its identity with *cadinene* was established by the prepn. of *cadinene-di-HCl*, m. 118°. Fractions 8, 9 and 10 on several distns. yielded a colorless oil, b_{98} 151-2° which soon crystallized completely and after 3 crystns. from ether-alc. m. 102-4°, $[\alpha]_{5461}^{15}$ 27.15° (3% soln. in $CHCl_3$). Analysis showed this substance to consist of a *diterpene* $C_{20}H_{32}F_2$, called *mirene*, which, on treatment with dry HCl in ether-AcOH, yields *mirene-HCl*, $C_{20}H_{33}Cl$, m. 97-8°, optically inactive in $CHCl_3$. On heating the mono-HCl salt with 10% excess of alc. KOH at 100° during 16 hrs., mirene is regenerated, which then m. 105°. The approx. compn. of the autumn oil is therefore as follows: *d- α -pinene* 36%, mirene 27%, *cadinene* 12%, *d-limonene* and *dipentene* 5%, cineole 2%, resinous material 5%, undetd. and loss 13%. From the water oil 0.02% of an acid liquid was obtained, which could be sepd. into *AcOH* and *iso-BuCO_2H*. An examn. of the spring oil showed it to consist of *d- α -pinene* 24%, *d-cadinene* 6%, mirene 47%. Thus the essential oil extd. later in the year contains a higher % of pinene and a lower % of mirene than that collected during the spring. A similar seasonal increase of the pinene content at the expense of terpenes of higher mol. wt. has been observed to occur in the essential oil of *Agatha australis* (C. A. 22, 2027).

C. F. VAN DUIN

Methods for the production of technical drugs. ANON. *Pharm. Presse* 33, 228-9 (1928).—Production of $FeCl_3$. The subject is treated under 3 headings: (1) prepn. of $FeCl_3$ soln., (2) oxidation of $FeCl_2$ to $FeCl_3$, (3) evapn. of the soln. and crystn. of $FeCl_3$.

W. O. E.

Estimation of free iodine and potassium iodide in the official tincture. K. WINTERFELD and H. SIECKE. *Apoth. Ztg.* 43, 852-4 (1928).—The results of an exptl. study of the official Ger. prepn. with respect to its evaluation are given in considerable detail.

W. O. E.

Spongia fluviatilis seu lacustris. W. PEYER. *Jahresbericht d. Caesar & Lorets A.-G. in Halle a. S.* 1925, 181-8; 1926, 111 pp.; *Chem. Zentr.* 1927, I, 2449.—Analysis of dried *Spongia fluviatilis seu lacustris* gave: moisture 5.6%, inorg. 55.2, insol. in 10% HCl 52.4, EtOH ext. 6.6, EtO ext. 3.2, N 2.59, protein 16.8%. The ashes contain Fe, Al, Ca, Mg, Na, CO_2 , K, PO_4 and NO_3 . A tincture prepd. from it showed a capillarity different from that described in the homeopathic pharmacopeia. The active constituent of the drug consists of SiO_2 needles which partly formed a solid structure (macroscle), and partly were loose in the parenchyme (microscle). The various forms are shown in illustrations. The drug is used in the more varied ways in homeopathy. The vogue of the drug (used under the name of "Badiassa") is due to its iodine content of 2.3 mg. per 100 g. of dry material.

A. L. HENNE

The outlook in pharmacology and pharmacy. JOHN ROSE BRADFORD. *Quart. J. Pharm.* 1, 3-6 (1928).

E. H.

The problem of active iron. K. KÖRSCHAU. *Verh. deut. Ges. inn. Med.* 1927,

398-9; *Ber. ges. Physiol. exper. Pharmakol.* **44**, 609; cf. *C. A.* **21**, 3531.—K. recommends for injections a soln. of ferrohdrocarbonate which has remained active toward benzidine and H_2O_2 after 4 weeks standing in sealed ampules. It was well tolerated by rabbits.

MARY JACOBSEN

The essential oil of leaves of "Hiba." So. UCHIDA. Tokyo Higher Tech. School. *J. Soc. Chem. Ind. Japan* **31**, 491-501(1928).—By steam distn. of 82.5 kg. of leaves of "Hiba" (*Thujaopsis dolablate*, Sieb. et Znce), was obtained 686 g. of an essential oil, light yellow, fresh odor, d_{16}^{25} 0.8857, n_D^{27} 1.4729, $[\alpha]_D + 27.67$, acid value 3.76, sapon. value 32.68, ester value 29.12, and ester value after acetylation 113|2. Compds. isolated from the oil are undercyclic acid, sabinene, dipentene, borneol, sabinol, bornyl and sabinyl acetates, a bicyclic sesquiterpene ($C_{15}H_{24}$, b. 270-80°, d_4^{25} 0.9232, n_D^{25} 1.4949, forming an addition product of light yellow liquid with 2 mol HCl), a monocyclic sesquiterpene alc. (b. 290-300°, d_4^{25} 0.9328, n_D^{25} 1.5049 and mol. refraction 70.60) and a tetracyclic diterpene ($C_{20}H_{32}$, b. 336°, d_4^{20} 0.19629, n_D^{20} 1.5131 and mol. refraction 84.92). About 50% of the oil is the terpene (a mixt. of large amt. of sabinene and a small amt. of dipentene), 22% the terpene alc. (sabinol and borneol, the former predominating). 10% the ester (mainly sabinyl acetate with a small amt. of bornyl acetate), 13% the diterpene, 3% sesquiterpene alc., 2% sesquiterpene and 0.1% undercyclic acid.

K. KASHIMA

The essential oil of "Hiba"-wood and its relation to the resistance of the wood to destruction by fungi. So. UCHIDA. Tokyo Higher Tech. School. *J. Soc. Chem. Ind. Japan* **31**, 501-3(1928).—By steam distn. of 353.1 kg. (H_2O content 27.73%) of sawdust of "Hiba"-wood (*Thujaopsis dolablate*, Sieb. et Znce), is obtained 3820 g. of the essential oil, reddish brown, d_{16}^{22} 0.9574, n_D^{22} 1.5110, $[\alpha]_D - 26.72$ in a 17.23% $CHCl_3$ soln., acid value 5.62, ester value 11.97 and sapon. value 17.59. The main component of the oil is a tricyclic inactive sesquiterpene, $C_{15}H_{24}$, of colorless slightly viscous liquid having good flavor, b. 261-2°, d_4^{22} 0.9458, n_D^{22} 1.5055 and mol. refraction 64.09. The essential oil is toxic to fungi which destroy the wood. For example, *Merlius lacrymans* Fr. cannot live in a culture medium contg. 0.1% of the oil. Although *Polyporus gilvus* Schw. can live in a culture medium contg. 0.1-0.2% of the oil, it cannot in a medium contg. 0.3% of the oil. Resistance of the wood to fungus action is therefore concluded to be due to the action of the oil; the content of the oil in the wood is about 1%.

K. KASHIMA

The essential oil of leaves of "Sawara." S. UCHIDA. Tokyo Higher Tech. School. *J. Soc. Chem. Ind. Japan* **31**, 642-50(1928).—By steam distn. of 94.4 kg. of leaves of "Sawara" (*Chamecypris prisifera*, Endl) was obtained 1004 g. (yield 1.07%) of an essential oil of light yellow color, fresh odor, d_4^{14} 0.8939, n_D^{14} 1.4710, $\alpha_D^{12} + 12.55$, acid value 1.50, sapon. value 55.20, ester value 53.70 and ester value after acetylation 64.49. The following compds. were isolated from the oil: pelargonic acid, undecylic acid, d - α -pinene, dipentene (liquid addn. product, $C_{10}H_{18}$.HCl), borneol, bornyl acetate and formate, a sesquiterpene alc. ($C_{15}H_{28}OH$, b. 290-300°, n_D^{24} 1.5002), and a tetracyclic diterpene ($C_{20}H_{32}$, b. p. 320-35°, d_4^{24} 0.9452, n_D^{24} 1.5125, mol. refraction 86.54). About 75% of the oil is the terpene (mainly α -pinene and a small amt. of dipentene), 20% the esters (mainly bornyl acetate and a small amt. of bornyl formate), 3% the alc., 2% diterpene and a very small amt. of the acid.

K. KASHIMA

The essential oil of leaves of "Hinoki." So. UCHIDA. Tokyo Higher Tech. School. *J. Soc. Chem. Ind. Japan* **31**, 650-9(1928).—By steam distn. of 77 kg. of leaves of "Hinoki" (*Chamecypris obtusa*, Endl) there is obtained 894 g. of an essential oil of light yellow color, fresh odor, d_4^{12} 0.9053, $\alpha_D^{12} + 41.25$, n_D^{12} 1.4794, acid value 0.60, ester value 75.37 and ester value after acetylation 100.2. The following compds. are isolated from the oil: a new cryst. sesquiterpene acid ($C_{14}H_{26}CO_2H$, named "Hinoki" acid, white silky threads or prisms, m. 166° (cor.), tasteless and odorless, insol. in boiling H_2O , sol. in alc. ether, etc.; its *Ag* salt is amorphous; *hydrochloride*, needles, m. 119°), d - α -pinene, d -limonene, d -borneol, bornyl acetate and monylate, a tricyclic 1-sesquiterpene ($C_{15}H_{24}$, b. 265-8°, d_4^{20} 1.5009, $[\alpha]_D - 15.67$ in a 3.8% alc. soln., mol. refraction 64.2%; addn. product with 1 mol HCl is a liquid having camphor-like odor), cadinene, a bicyclic d -sesquiterpene alc. ($C_{15}H_{28}OH$, b. 290-5°, d_{16}^{25} 0.9607, n_D^{20} 1.5020, $[\alpha]_D + 18.0$ in a 7.3% $CHCl_3$ soln., mol. refraction 68.22; it gives a Bz ester) and a tetracyclic inactive diterpene ($C_{20}H_{32}$, b. 340-3°, d_{16}^{25} 0.9632, n_D^{20} 1.5190, mol. refraction 85.21). About 40% of the oil is the terpene (a mixt. of d -limonene and d - α -pinene, the former

predominating), about 25% the ester (bornyl acetate and a very small amt. of the nonylate), 20% the sesquiterpene (mainly a tricyclic sesquiterpene and a small amt. of cadinene), about 10% the alc. (mainly a bicyclic *d*-sesquiterpene alc.) and about 5% tetracyclic inactive diterpene.

Tobacco industry of Mauritius. ANON. *Bull. Imp. Inst.* 26, 135-40(1928).—Samples of tobacco leaf grown and graded in Mauritius were found to be of promising quality. Analysis of 2 samples gave: H₂O 14.0, 14.0; nicotine 3.88, 5.41; N 2.02, 2.53; ash 10.3, 11.1%, resp. The ash contained; CaO 34.75, 33.12; MgO 11.31, 9.93; K₂O 17.74, 17.42; Na₂O 1.55, 1.18; SO₃ 5.78, 7.16; Cl 3.99, 3.67; CO₂ 20.72, 23.62%, resp.

The amellaroside, a new glucoside from the bark of the *Amelanchier vulgaris* Moench. M. BRIDEL, C. CHARAUX AND G. RABATÉ. *Compt. rend.* 187, 56-7(1928).—With fresh or dried twigs of the *Amelanchier vulgaris* Moench emulsine characterizes a hydrolyzable glucoside (I) α_D -86.56°. The twigs are extd. with 92% EtOH. The residue from the distn. of the EtOH is dissolved in water treated with MgO, re-extd. with hot 92% EtOH, distd., and the residue taken up in a small quantity of boiling water. Ten g. of I are obtained from 1 kg. of twigs or bark. I with FeCl₃ gives a violet coloration; 1 g. reduces 0.0641 g. of glucose; with 3% H₂SO₄ 1 g. gives 0.6043 g. of a reducing sugar α_D + 51.4°. The non-glucidic product is called *ameliarol* m. +110° (Maquenne block), sublimes at +120°, index of enzyme reduction 232, index of hydrolytic acid reduction 229.

Estimation of alkaloidal principles in the pharmaceutical form by the mercurimetric method. AL. IONESCO-MATIU AND H. VÂRCOVICI. *Bull. sci. pharmacol.* 35, 417-21(1928); cf. *C. A.* 21, 2445, 3575.—The method may be applied with success to the detn. of the alkaloidal content of pharmaceutical preps.

Characterization of the gum of *Acacia Verek*. A. HAMY. *Bull. sci. pharmacol.* 35, 421-2(1928).—The rotatory power of the gum of *Acacia Verek* ranges from -29 to -38. Gums from other species of *Acacia* give a + rotation.

Pharmacodynamic study of ephedrine. PAUL BOYER AND JEANNE LÉVY. *Bull. sci. pharmacol.* 35, 431-58(1928).—An elaborate review of the subject is given with 193 references to the literature.

New organic aromatic compound of bismuth suitable for intravenous injection in the treatment of frambesia. R. N. CHOPRA, J. C. GUPTA AND M. N. MULLICK. *Indian Med. Gaz.* 63, 361-3(1928).—The compd. is the Na salt of *p*-aminophenylbismic acid in combination with urea. The formula of the latter is NH₂CONHC₆H₄BiO(OH)ONO, and contains 50.1% of Bi. The substance has a low toxicity of 0.5 g. per kg. to white mice, and is a remarkable curative agent in frambesia.

Rational control of the production of tablets, pills, etc. HÅKAN SANDQVIST. *Svensk Farm. Tid.* 32, 101-5, 128-30, 181-4, 207-9, 249-51, 293-6, 337-40, 385-7(1928).—A better control of the wts. and contents of pills, tablets, etc., produced in large quantities is advocated and the use of the statistical methods for this purpose discussed 60/√wt. is suggested as limit of tolerance.

Pharmacopoea Suesica. X (1925). T. DELPHIN. *Svensk Farm. Tid.* 32, 125-7, 184-7, 205-7, 232-4, 276-8, 313-6, 411-3, 449-51(1928).—A critical review in which many items are discussed in detail.

Two simple tests for impurities in anesthetic ether. EDWIN B. ROBINSON. Univ. of Manchester. *Lancet* 1928, I, 856.—The test for aldehydes was described by W. Wobbe. Ether is tested by adding 10 cc. of the sample to 2.5 cc. of a fresh alk.-ammoniacal soln. of AgNO₃. Presence of aldehyde is detd. by a black ring or ppt. or a Ag mirror. To test for peroxides add equal parts (1.25 cc.) each of 50% KI soln. and 1% phenolphthalein soln. to 10 cc. of ether; in 2 min. a red color becomes apparent if peroxides are present.

A non-irritating silver-arsenic compound. HAROLD O. LONG. *Lancet* 1928, I, 964-5.—A new compd., metarseno-argenticum (14% Ag and 16-17% As), is suggested as an improvement for intramuscular injections over the formerly used compd. arseno-argenticum (13-15% Ag and 21-24% As), since it is much less irritating to the tissues and causes very little pain. A possible but not entirely satisfactory formula for metarsenobillon is 3.4-NaO₂SOCH₂NH(HO)C₆H₄As₂.

Biological standardization of insulin. R. WERNICKE, F. MODERN AND C. M. SCOTT. *Anales asocn. quim. Argentina* 15, 324-36(1927); Cf. *Publications of the League of Nations Health* 1926, III, 7.—The preliminary test on white rats consists in detg. the dose of insulin capable of producing the same percent of symptoms of hypoglycemia as a known dose of standard insulin, both insulins being injected subcutaneously into an equal no. of rats raised and kept under appropriate conditions. The

rats weighed 15 to 20 g. each, and were starved for 14 to 16 hrs. in a moderately warm place, with water available. The injections were 0.5 cc. for each 20 g. wt. of rat. All lots of rats were kept during the tests in a vessel maintained at 37° to 38° by being partially submerged in water heated to this temp. The rats were observed for 2 hrs. from the instant of injection, and the time was noted at which symptoms of hypoglycemia appeared, either as convulsions or inability to get up after being turned over on their backs. At the end of 2 hrs. the no. of rats in each lot which show symptoms was noted to det. the proportion affected. This preliminary test was repeated with different concns. of insulin, until the degree of diln. of the unknown insulin which equals standard insulin was reached. This value was checked by tests on rabbits; the animals weighed 1800 to 2200 g. each and were starved 24 hrs. with water available; 1 clinical unit of insulin per kg. of animal wt. was injected subcutaneously without causing convulsions. After 3 to 4 days of such tests 10 to 12 rabbits which endure it can be used, starved 24 hrs. as before. Initial glucemia is detd. on a sample of blood from the marginal vein of the ear. Animals of nearly equal wt. are selected. Standard and unknown insulin solns. are prepd. contg. 0.5 clinical units per cc., based on the tests with rats, and 2 cc. (1 clinical unit) of each injected subcutaneously. At the end of each 5 hrs. after injection a 0.1 cc. blood sample is taken, mixed together, and the final av. glucemia of each animal for the first 5 hrs. detd. by the Hagedorn and Jensen method. The difference between the initial and av. final glucemia of each animal gives the drop in glucemia, Δ , and the percent of this value with respect to the initial glucemia called the hypoglycemic action. These operations should be repeated 3 or 4 days later on the same animals and under the same conditions except injecting the unknown insulin into the lot which had first received the standard insulin, and *vice versa*. Comparison of the av. values of hypoglycemic action of each insulin on all the rabbits allows establishing the relation of activity of both solns., since they are used in direct proportions. The quotient of the av. values of hypoglycemic action is equal to the quotient of the concns. in clinical units of solns. of insulin injected. Since the concn. of the standard insulin is known, the other is defined. Itemized test data are shown in tables. This method, adopted in the Bacteriological Institute, follows that published by the League of Nations.

E. M. SYMMES

Arsenious oxide in neutral and alkaline solution. WM. H. MILLAR. *Pharm. J.* 120, 214-5, 224-5; *Chemist and Druggist* 108, 352-3(1928).--Recent views on the chem. reaction in the prepn. of *Liquor arsenicalis* Brit. Pharm. agree that KAsO_2 is formed by the interaction of K_2CO_3 and As_2O_3 . Upon measuring the quantity of CO_2 given off, M. finds that 8% of the quantity of K_2CO_3 directed in the Brit. Pharm. is sufficient to bring all the As_2O_3 used into 1% soln. By interaction of As_2O_3 and K_2CO_3 in the new proportions, KAsO_2 is formed, detd. by titration with 0.1 N H_2SO_4 . In another expt., the quantity of K_2CO_3 was further reduced to 4%; with this, complete soln. of As_2O_3 was effected. The soln. was then neutralized with 0.1 N H_2SO_4 (methyl orange). This neutral 1% soln. is very stable toward light and air, and is compatible with both acid and alkali; the small quantity of K_2SO_4 present is comparatively inert. Theories are adduced to explain the high sply. of As_2O_3 in the dil. K_2SO_4 soln. The concd. soln. of As_2O_3 in dil. K_2CO_3 seems to be of colloidal nature.

S. WALDBOTT

Control of coca leaves and its preparations according to the International Convention of Geneva. PIERRE BRETEAU. *J. pharm. chim.* 7, 492-5(1928).--Com. coca leaf and its preps. should not be classed with opium; official control should be confined to supervision of statistics in manuf. and trade.

S. WALDBOTT

Sclerocarya caffra, Sond. MARIE G. BRANDWIJK. *Pharm. J.* 120, 172, 192-3, 212(1928).--The bark of this S. African tree is said to be useful in malaria. The dried fruit kernels yield 60% of a non-drying oil suitable for soap manuf. and possibly for edible use (cf. *Bull. Imp. Inst.* 1920, 481; 1923, 129; and Rindl, *C. A.* 15, 3759). A systematic chem. study of the bark showed about 20.5% of tannin present, and a trace of alkaloids; glucosides or neutral principles are absent. No poisoning followed the subcutaneous injection of the alc. ext. into a cat, but very drastic local effects were produced. The alleged usefulness of the bark in malaria is doubted. A list of 12 references is given.

S. WALDBOTT

Studies in toxicologic chemistry. II. The formaldehyde-sulfuric acid reaction of the opium alkaloids. VICTOR E. LEVINE AND ESTELLE A. MAGIERA. *J. Lab. Clin. Med.* 12, 773-89(1927).--The $\text{CH}_2\text{O}-\text{H}_2\text{SO}_4$ reaction is given by all types of phenols and their various derivs., phenolic glucosides and phenolic alkaloids. Nitrated phenols do not give it. The reaction can be used for detecting phenols in biologic fluids and is also given by morphine and its allied alkaloids because of their phenolic character. The color produced by phenols differs markedly from that given by the morphine alka-

lids, although some phenols of biologic occurrence, such as *p*-cresol and pyrocatechol, give colors that are indistinguishable from those produced by the alkaloids. Many tests known for the morphine alkaloids have been correlated and classified into these 6 type reactions: (1) tests involving pptn. by the so-called alkaloidal reagents, which are general for all alkaloids (phosphomolybdic acid, I in KI, K | Bi | iodide, K | mercuric iodide); (2) tests involving reduction of the reagents used; (3) tests involving oxidation of the alkaloid; (4) tests depending upon the presence of the phenol group (5 different reagents); (5) tests involving the preliminary formation of apomorphine; (6) Biological tests. It is suggested that clinical tests for these alkaloids should include at least one reaction taken from each of these 6 characteristic type reactions. E. W. W.

Essential oil of the bark of Cinnamon sintok. Bl. T. KARIYONE AND S. MOROTOMI. *J. Pharm. Soc. Japan* **48**, 563-5(1928).—The essential oil of the bark of *Cinnamomum sintok*, Bl., a wild plant in Dutch East Indies, was obtained in the yield of 6%, $[\alpha]_D^{15}$ -1.84° , d_4^{15} 1.0410, n_D^{15} 1.5298, acid no. 850, sapon. no. 11.34, total phenol 84% (by vol.). It contained 76.7% eugenol (Thom's method). The phenolic constituent b_1 120-1°. The non-phenolic part of the oil contains cineole and sesquiterpene.

NAO UYEI

Estimation of alkaloids in Scopolia extract. S. AOYAMA, S. NAGAE AND T. DAIGO. Tokyo Imp. Hyg. Lab. *J. Pharm. Soc. Japan* **48**, 566-75(1928).—A comparison of CHCl_3 (I) and Et_2O (II) as a solvent for the extn. of the alkaloids in *Scopolia* ext. showed that I always gave quant. higher values than II because of the extn. of tropine, a physiol. inactive constituent, while II gave results which represented the amt. of active constituents. The following is recommended for the detn. of alkaloids in the ext.: Shake 3 g. ext. for 30 min. with 5 cc. H_2O , 30 cc. II and 4 cc. concd. NH_4OH . Add 1.5 g. tragacanth powder and shake again. Filter the clear Et_2O layer, evap. 20 cc. of the filtrate, and dry at 60° . Dissolve the residue in 1 cc. abs. alc. Add 5 cc. H_2O , 5 cc. 0.1 N HCl, and titrate the soln. with 0.1 N KOH using methyl red. NAO UYEI

Estimation of volatile oil of clove and cinnamon powder. K. SUTO. *J. Pharm. Soc. Japan* **48**, 576-83(1928).—A comparative study of U. S. P. method and a slightly modified method for detn. of volatile oil of clove and cinnamon powder is reported. N. U.

Essential oil of *Artemisia vulgaris* L., var. *parviflora*, Maxim. K. TAKASHIMA. *J. Pharm. Soc. Japan* **48**, 590-2(1928).—From the flowers of *Artemisia vulgaris* L. var. *parviflora*, Maxim., was obtained 0.05-0.092% of essential oil, sp. gr. 0.86, having a characteristic odor and possessing a venenous anthelmintic action. NAO UYEI

Synthetic drugs. I. G. FARBENIND. A.-G. Brit. 282,143, Sept. 11, 1926. 4-Amino-2-styrylquinoline and its nuclear substitution products are prepd. from 2-methylquinoline compds. substituted in the 4-position by a halogen, alkoxy, hydrazino, carbamino or carbazido group, by exchanging these substituents for the amino group and converting the 2-methyl group into a styryl residue; e. g., a 4-halogen- or 4-alkoxy-2-styrylquinoline may be heated with NH_3 or with a primary or secondary amine, a 4-hydrazino-2-styrylquinoline may be reduced, the 4-carboxylic acid amide of a 2-styrylquinoline may be treated with a hypohalogenite, the 4-carboxylic acid azide of a 2-styrylquinoline may be treated with water or alc. and the resulting urea or urethan then hydrolyzed, or a 4-substituted-2-methylquinoline may be converted by any of the specified methods into a 4-amino-2-methylquinoline and the latter then condensed with an aromatic aldehyde. The products possess bactericidal properties. Examples are given of the production of 4-amino-6-ethoxy-2-styrylquinoline, 2-styryl-4-amino- β -naphthoquinoline, 2-*m*-aminostyryl-4-amino-6-ethoxyquinoline, and similar compds.

Synthetic drugs. I. G. FARBENIND. A.-G. Brit. 282,453, Dec. 20, 1926. In the

process described in Brit. 267,169 (C. A. 22, 1216) the external N atom is introduced in heterocyclic combination, *e. g.*, in the form of piperidyl or pyrrolidyl; also, the aliphatic connecting link between the N atoms may be replaced by a residue of hydroaromatic or heterocyclic character; the ring system contg. N and the connecting link may contain further substituents. *N*-(β -chloroethyl)-piperidine is condensed with 8-aminoquinoline; 1-dimethylamino-2-bromocyclohexane is condensed with 6-methoxy-8-aminoquinoline; 2,2,6,6-tetramethyl-4-brom-N-methylpiperidine is condensed with 6-methoxy-8-aminoquinoline; a thiazine is obtained by joint oxidation and condensation of *N*-methylpiperidylethyl-aniline and *p*-aminodimethylaniline. *N*-Methylpiperidylethylaniline is made by condensing *N*-(β -chloroethyl)-piperidine with methylaniline.

Synthetic drugs (metal-mercapto acid esters). SCHERING-KAHLBAUM A.-G. Brit. 282,427, Dec. 16, 1926. Metal-mercapto acid esters are made by treating a mercapto acid ester of the aliphatic, aromatic or heterocyclic series with an oxide or salt of a metal such as Au, Ag, As, Sb or Bi, preferably in the presence of a solvent. The products are sol. in oils and other org. solvents and possess therapeutic properties. Examples are given of the reaction of Bi oxide with thiosalicylic acid butyl ester and of Sb_2O_3 with thiosalicylic acid methyl ester by heating the materials in a stream of H or CO_2 ; the same products may also be obtained by reacting on the mercapto acid ester in ether soln. with an ethereal soln. of Bi or Sb compds. such as the bromide or iodide which are sol. in org. solvents. Ag and Au mercapto acid esters are obtained by treating a soln. of a mercapto acid ester in an org. solvent with alc. AgNO_3 or a soln. of K auribromide in acetic ether.

Cinchona alkaloids. CHEMISCHE FABRIK VORM SANDOZ Brit. 282,356, Dec. 17, 1926. Cinchona alkaloids are converted into their salts with bile acids such as cholic, glycocholic, taurocholic, desoxycholic, dehydrocholic and apocholic acids. The products possess antiparasitic properties and their soln. in water is increased by addn. of urea or urethan. Natural or synthetic alkaloids may be employed such as quinine, quinidine, cinchonine, dihydroquinine, and the Et, iso-Am and *n*-octyl ethers of dihydrocupreine.

Arylated azotized diaminopyridines. IVAN OSTROMUISLENSKII (to The Pyridium Corp.). U. S. 1,680,108, Aug. 7. These compds. are suitable for use in the treatment of germ infections such as produced by various cocci. Diazotized aniline may be coupled with 2, 6-diaminopyridine, a sol. acid salt formed, *e. g.*, by use of HCl, and the salt may be purified by treatment with a suitable alk. substance such as dil. NH_4 soln. and, after sepn. of by-products, the purified basic material may be treated with HCl to reform an acid salt of phenylazodiaminopyridine.

Pyridium. IVAN OSTROMUISLENSKII (to The Pyridium Corp.). U. S. 1,680,109, Aug. 7. A diazotized amine of the aromatic series such as diazotized aniline is directly coupled with diaminopyridine salts in HCl soln.; over one-half but less than 2 mol. proportions of the diazotized amines are used.

Neopyridium. IVAN OSTROMUISLENSKII (to The Pyridium Corp.). U. S. 1,680,110, Aug. 7. A di-Na salt of diamino pyridineazophenyl-*o*-carboxylic acid, probably having the formula $\text{C}_6\text{H}_4(\text{COQNa})\text{N}_2\text{C}_6\text{H}_4\text{NNH}_2\text{NNa}$, is obtained by treating the normal salt of diaminopyridinephenyl-*o*-carboxylic acid with org. acid such as HOAc and treating the product with NaOH.

1-Alkoxyethyl-3,7-dimethylxanthines. KARL SCHIRANZ and CLEMENS LUTTER (to Winthrop Chemical Co.). U. S. 1,679,053, July 31. 1-Alkoxyethyl-3,7-dimethylxanthine is made by treating the Na salt of theobromine with chloromethyl ethyl ether. It forms needles m. 152-3°. The corresponding iso-Pr deriv. m. 107-8°, the Pr deriv. 130-2°, the Bu deriv. 102-3°, the iso-Bu deriv. 128-9°, the benzyl deriv. 95-7° and the allyl deriv. 108-10°. These compds. possess diuretic properties and form double salts with org. acid salts. Together with a salicylate soln. they form neutral solns. suitable for subcutaneous use.

Monohydroxy- ω -aminoacetophenone derivatives. HELMUT LEGERLOTZ. U. S. 1,680,055, Aug. 7. *p*-Hydroxy- ω -methylaminoacetophenone (colorless leaflets m. 147-8°) is made by reaction of methylamine on *p*-benzoyloxy- ω -bromacetophenone, sepg. the cryst. mass from the reaction mixt. and purifying it by transforming it into a hydrochloride, recrystg. the latter and sepg. the base. The hydrochloride m. 239-40°. *p*-Hydroxy- ω -diethylaminoacetophenone m. 177-8°; its hydrochloride m. 194°. These compds. may be used as intermediates in the manuf. of other therapeutic compds.

Substituted 4,4'-dihydroxybisacylamino arsenobenzenes. LOUIS BENDA (to I. G. Farbenind. A.-G.). U. S. 1,680,845, Aug. 14. Details are given for the production of 3,3'-dichloro-4,4'-dihydroxy-5,5'-diacetamino-arsenobenzene and the corresponding 2,2'-dichloro compd. These compds. are insol. in water, easily sol. in dil. caustic alkali

sols. and somewhat sol. in alc. They may be used in the treatment of syphilis and may be administered by the mouth.

2-Hydroxy-3-bromo-5-pyridinearsonic acid. ARTHUR BINZ and CURT RÄTH. U. S. 1,680,587, Aug. 14. See Brit. 263,142 (C. A. 22, 140).

Phenyldiazo- α,α -diaminopyridine dihydrochloride. IVAN OSTROMUISLENSKII (to The Pyridium Corp.). U. S. 1,680,111, Aug. 7. This compd. forms fine needle-like silky glistening crystals with violet shading. It is made by treating the corresponding mono-hydrochloride (pyridium) with not less than 10% of HCl and may be used for therapeutic and bactericidal purposes.

Laxative. RICHARD PASTERNAK (to Charles Pfizer & Co.). U. S. 1,681,361, Aug. 21. An amorphous laxative substance is formed by treating phthalic anhydride and phenol with the usual condensing agents to form phenolphthalein, extg. the reaction product with an alkali, reprecip., *e. g.*, by HOAc or H₂SO₄, dissolving the ppt. by a solvent such as alc., crystg. out the phenolphthalein, and extg. the new product from the residue after crystn. by use of ether.

Nutritive substance. KARL STEJSKAL. Fr. 634,502, May 17, 1927. See Brit. 271,120 (C. A. 22, 1655).

Antirachitic products. HARRY STEENBOCK (to Wisconsin Alumni Research Foundation). U. S. 1,680,818, Aug. 14. See Brit. 236,197 (C. A. 20, 953).

Preparing antirachitic substances. AUGUST J. PACINI (to Charles M. Richter). U. S. 1,681,120, Aug. 14. Ext. of ergot of rye or other materials contg. growth-producing substances are treated to convert some of the latter into antirachitic products by use of rays longer than about 3022 Å U.

Diastatic product. KEIZO WOYENAKA and TATSUO OKOCHI (to Takamine Ferment Co.). U. S. 1,680,926, Aug. 14. A culture medium such as wheat bran is impregnated with an aq. soln. of Na salicylate and NaF in a closed receptacle and steamed to effect sterilization, a dil. inorg. acid such as HCl is then added to liberate the acid radicals of the antiseptics, and the material is inoculated with *Aspergillus oryzae* spores and incubated.

Parathyroid product. LOUIS BERMAN. U. S. 1,680,660, Aug. 14. Comminuted parathyroid glands are extd. with water contg. HPO₃ and the aq. ext. is subjected to a treatment, to sep. proteins, comprising neutralization of the soln. with NaOH, filtering off the ppt., rendering the soln. alk. and forming a phosphate gel, filtering off and neutralizing the liquid.

Urease preparation. OTTO LIND. U. S. 1,679,250, July 31. In producing a stable, dry, easily sol. urease prepn. urease-contg. vegetable materials such as soy beans are extd. with water, alkali metal phosphates are added to the aq. ext. and the ext. is freed from moisture by spray desiccation.

Biliary acids. CHÉMISCHE FABRIK VORM. SANDOZ. Fr. 634,234, April 20, 1927. See Brit. 269,925 (C. A. 22, 1375).

Bacterial remedies. H. BECKER. Brit. 282,434, Dec. 16, 1926. A prepn. for use in the treatment of diseases such as tuberculosis or diabetes comprises a culture of "*Bacillus erodians*," originating from the intestines of dogs or doves, alone or with a digestive enzyme, which may be formed into pills or the like coated with keratin so as to be liberated only in the lower part of the intestine. The culture also may be administered *per anum* or given to animals with their fodder in the form of a potato culture.

Rinsing and cleansing liquid for use in the mouth, nose or ears. KLEMENS BERGL AND WALTER DIETRICH (to the Firm Max Gottlieb). U. S. 1,681,320, Aug. 21. The container of an injection or irrigating device is filled with water shortly before use and to this there are added carbonic acid salts such as NaHCO₃ and tartaric acid or other suitable solid acids; the liquid is allowed to flow to the point of use under the pressure of the gas generated by reaction of these added reagents. An app. is described.

"Tobacco substitute" with therapeutic properties. FRANK K. CHISHOLM. U. S. 1,680,860, Aug. 14. The cell structure of semi-dried natural eucalyptus leaves is caused to burst by rolling the leaves, they are macerated in an aq. soln. contg. about 10% each of glycerol and KNO₃ and are heated, compacted under pressure in heated molds and further cured by aging.

Testing nicotine solutions. EDWIN COX (to Tobacco By-Products and Chemical Corp.). U. S. 1,678,636, July 31. In detg. the nicotine content of sols. such as dipping bath the soln. is acidified and WO₃ is added in at least sufficient quantity to combine with all org. impurities, and the soln. is then directly titrated with silicotungstic acid.

Tobacco products. A. SCHAARSCHMIDT and M. POPOFF. Brit. 282,369, Dec. 20, 1926. Tobacco waste such as cuttings or dust is mixed with acetylcellulose or other

acid esters of cellulose or hydrocellulose and solvents for the latter and formed into films for use as cigaret or cigar wrappers or formed into a cake which can be sliced or comminuted for smoking.

Dental powder. LOUIS C. LUDIN. Fr. 633,684. Sept. 6, 1926. A dental powder is made from powdered pumice, oil of anise, $\text{Ca}(\text{HCO}_3)_2$, and Marseilles soap.

Disinfectants. DEUTSCHE GOLD- UND SILBER-SCHNEIDANSTALT VORM. ROESSLER. Fr. 634,519, May 17, 1927. See Brit. 271,514 (C. A. 22, 1643).

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

Hydrochloric acid absorption, its mechanism and the apparatus necessary. B. WAESER. *Chem. Fabr.* 1928, 101-2.—Data from literature are given, including relations between gas and soln. concns., calcons. of cooler dimensions, back pressures of absorption towers, and various data for different tower packings. For the prepn. of very pure synthetic acid fused silica only must be used, and stoneware, coke, packing rings, etc., excluded. For joints a mixt. of pitch with BaSO_4 or clay and asbestos is recommended. B. C. A.

Use of aluminum in the manufacture of nitric acid. A. A. SVESHNIKOV. *J. Chem. Ind. (Moscow)* 4, 321-4(1927).—In HNO_3 manuf., tubes, pipes, condensers, etc., hitherto made of earthenware or of glass, have lately been replaced by Al, the main advantage of which is that its coeff. of heat cond. is 12.4-13.0, whereas that of earthenware is only 0.7-1.0. This permits a much more rapid condensation of HNO_3 . Since these parts are exposed to the action of both liquid and gaseous HNO_3 , S. investigated the dissolving action on Al of HNO_3 in both phases and at various temps. He found that the max. corrosion corresponds to acid fumes contg. 30-40% of monohydrated HNO_3 . Stronger and weaker acids have much less effect on Al. The temp. of operation has by far the greatest influence on the soly. of Al in the acid; the higher the temp. the greater the dissolving effect. Drawn Al is incomparably more resistant to the acid than cast Al. The smoother the surface of Al the less it is affected by the acid. It is practicable to use Al pipes and condensers in the manuf. of HNO_3 , and to use Al containers for storage of weak and of strong HNO_3 . BERNARD NELSON

Use of a Valentiner still for concentration of dilute nitric acid. B. DONAT. *J. Chem. Ind. (Moscow)* 4, 750-3(1927); 5, 216-8(1928); (cf. C. A. 3, 2039).—A com. method of concn. of 36° Bé HNO_3 obtained by NI_3 oxidation has been worked out and used for a year in a Russian plant. To avoid losses of HNO_3 due to rise in temp. during preliminary mixing of dil. HNO_3 with concd. H_2SO_4 large tanks are used, utilizing only part of their capacity, thus avoiding expensive artificial cooling. Distn. of the mixed acids *in vacuo* gives 97.82% HNO_3 contg. less than 2% N oxides. The spent acid contains 82-85% H_2SO_4 , is free from HNO_3 , and can be concd. again. Al condenser tubes are recommended. The acid corrosion of the still is insignificant. B. N.

The production of concentrated nitric acid by oxidation of ammonia under pressure. GIACOMO FAUSER. *Giorn. chim. ind. applicata* 10, 183-95(1928); *Chem. Met. Eng.* 35, 474-8.—There are various reasons for the failure up to the present time to obtain very concd. HNO_3 by the oxidation of NH_3 , chief among which are the impossibility of oxidizing more than 90% of the NH_3 , the difficulty of absorbing by water the last traces of N oxides and the conditions of equil. of the reaction. In practice not even 60% concn. is reached. By extended and systematic researches on the oxidation of NH_3 in the presence of Pt as catalyst, under different conditions of pressure and velocity of the current of gas, and with different proportions of air and of O_2 in the oxidizing mixt., it was found that when NH_3 is oxidized with air enriched with O_2 and under pressure (5 atm.) the process is much improved. The absorption of nitrous vapors is more efficient, so that HNO_3 of 75% concn. (theoretical 77.7% concn.) can be obtained, the wt. of Pt is greatly reduced and the plant is relatively very small. The process has already been applied industrially in 2 plants having a capacity of 100,000 quintals of 48° Bé. HNO_3 per yr. The velocity of oxidation of nitrous vapors increases rapidly with increase of pressure, and absorption is much more nearly complete, which allows a great reduction in the size of the towers. The small proportion of additional energy required because of the pressure is compensated by the various advantages, particularly by the lower cost of the plant and the greater concentration of the acid. In developing the process, a systematic study was made of the influence of pressure on the oxidation of NH_3 , on the rate of peroxidation of NO, on the reaction between NO_2 and H_2O ,

and on the heat transmission, the recovery of energy and the resistance of Cr steels to HNO_3 . Within the limits studied, the pressure has no influence on the yield by oxidation of NH_3 , while enrichment of the air with O_2 increases the yield. Pressure has a great influence on the oxidation of NO, e. g., at atm. pressure 98% of NO was transformed into NO_2 in 1200 sec., while at 5 atm. pressure 98% was transformed in 59 sec. The rate of oxidation of NO increases roughly with the square of the pressure. This in itself explains the relatively small plant required. The influence of the pressure on the polymerization of NO_2 to N_2O_4 , the coeff. of absorption of N_2O_4 by water and the transformation of the dissolved N_2O_4 into HNO_3 were also studied and quant. data recorded. The process could not have been developed industrially except by the use of Cr steel equipment, which tests showed to be highly resistant to HNO_3 and to be by far the best metal of which to construct the equipment. The exptl. results and the industrial process developed from them are described in great detail, the data being recorded in tabular and graphical forms, and the large-scale plant equipment being illustrated with photographs and diagrams

C. C. DAVIS

Formation of ammonium phosphate in gaseous reaction. F. V. BRITZKE AND A. P. DUNAIEV. *J. Chem. Ind. (Moscow)* 5, 161-70 (1928).—It is known that P distd. in elec. furnaces with C oxidizes to gaseous metaphosphoric acid, which by the action of H_2O vapors, and NH_3 gas can, under certain conditions, be transformed into NH_4 orthophosphates (cf Ross, *Am. Fertilizer* 57, 40 (1922)). $(\text{HPO}_3)_x$ suspended as a mist, or H_2O vapor and NH_3 gas, can give 2 types of reactions: (a) addn. of NH_3 to HPO_3 or to products of its hydration; (b) addn. of H_2O to HPO_3 or to $\text{HPO}_3 + \text{H}_4\text{P}_2\text{O}_7$, and the products of reaction may be either meta-, pyro-, or orthophosphates and their hydrates, the temp. being the main factor influencing the results. All NH_4 phosphates, particularly the orthophosphates, are unstable at high temps. and finally are converted into metaphosphoric acid according to the following 4 reactions: I $(\text{NH}_4)_2\text{HPO}_4 = \text{NH}_4\text{H}_2\text{PO}_4 + \text{NH}_3$; II $2(\text{NH}_4)_2\text{HPO}_4 = (\text{NH}_4)_2\text{H}_2\text{P}_2\text{O}_7 + 2\text{NH}_3 + \text{H}_2\text{O}$; III $(\text{NH}_4)_2\text{HPO}_4 = \text{NH}_4\text{PO}_3 + \text{NH}_3 + \text{H}_2\text{O}$; IV $(\text{NH}_4)_2\text{HPO}_4 = \text{HPO}_3 + 2\text{NH}_3 + \text{H}_2\text{O}$ (Knorre, *Z. anorg. Chem.* 24, 393 (1900)). To study the influence of temp. and time, 1.5 g. $(\text{NH}_4)_2\text{HPO}_4$ was placed in a thermostat, weighed from time to time, and finally analyzed. At 100° the salt lost by evapn. of NH_3 about 0.38% during the first 15 min., but the speed of NH_3 evapn. gradually decreased with time, and after 26 hrs. 15 min. a const. wt. was reached. The total loss was 13.1%, the residue consisting of $\text{NH}_4\text{H}_2\text{PO}_4$, while $\text{P}_2\text{O}_7^{--}$ and PO_3^- were absent. At 120° the original speed of evapn. was 1.28% for the first 15 min., const. wt. was reached after 22 hrs. 45 min., the total loss was 13.08 to 13.05%, and the residue had the same compn. as in the test at 100° . At 168° the original speed was 10.39% in the first 15 min., after 30 min. it dropped sharply to 0.37%, after 52 hrs. 40 min. the wt. was not yet const. and analysis of the residue gave $\text{P}_2\text{O}_7^{--}$, PO_3^- , P_2O_5 71.50 to 71.57%; NH_3 10.5 to 10.33%. The results are shown as curves, from which it becomes apparent that the decompn. of $(\text{NH}_4)_2\text{HPO}_4$ by heat takes place according to reactions a and b independently of one another with different speeds and at different temps. The decompn. of reaction I is complete at 100° ; the decompn. of reaction II does not take place at 100° and 120° ; the speeds of the reactions II, III and IV are, at the same temp., considerably less than the speed of the reaction I. Since type a reactions have not hitherto been studied sufficiently, the dissocn. pressures of $(\text{NH}_4)_2\text{HPO}_4$ within the temp. limits of 98 – 147° conforming to the equil. $(\text{NH}_4)_2\text{HPO}_4 \rightleftharpoons \text{NH}_3 + \text{NH}_4\text{H}_2\text{PO}_4$ were detd.; the data satisfy the Clausius-Clapeyron equation. These data were verified by thermochem. calcn. from the heats of neutralization and of dissolution. The results obtained by calcn. confirmed those obtained by expt. It is evidently a reversible reaction. The literature is abundant on type b reactions, but the data given by different authors are not in agreement because the results depend on the structure metaphosphoric acid happens to possess. In practice $(\text{NH}_4)_2\text{HPO}_4$ is obtained at temps. not above 130° in the presence of an excess of NH_3 and H_2O , but without complete utilization of NH_3 . The amts. of the latter to be taken depend on the temp., and can be calcd. from the partial pressures of NH_3 in the gases. By varying the quantity of NH_3 any desired mixt. of mono- and diphosphate can be obtained. $\text{NH}_4\text{H}_2\text{PO}_4$ can be obtained at temps. below 130° with complete utilization of all reagents by taking 2 mols. of NH_3 per mol. of P_2O_5 . The interaction of phosphoric acid and NH_3 , with formation of products containing 2 mols. of NH_3 per mol. of P_2O_5 takes place instantly and is not influenced by the speed of a current of inert gases, but in the formation of $(\text{NH}_4)_2\text{HPO}_4$ (4 mols. of NH_3 per mol. of P_2O_5) the speed of the reaction depends on the temp. and on the partial pressure of NH_3 in the working gas. The concn. of $(\text{HPO}_3)_x$ has no influence on the reaction. Complete utilization of metaphosphoric acid is thus possible even in case of low concn. in the distn.

gases of P. The hydration of metaphosphoric acid depends on the conditions of its formation, since its structure depends on them. The product of reaction, NH_4 phosphate, seps. as a smoke and technically can be condensed only in a Cottrell app. All other methods of condensation tried gave unsatisfactory results. NH_4 phosphate is obtained in a high degree of purity in the form of dry crystals.

BERNARD NELSON

Refining commercial barium chloride. I. F. ADADUROV. *J. Chem. Ind. (Moscow)* 5, 219-20(1928).—A com. BaCl_2 had the following compn: $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$ 97.10%, PbS 0.05%, PbCl_2 0.60%, FeCl_2 0.02%. Its color was gray from PbS formed during manuf. while evapg. in Pb vessels its soln. contg. free S and H_2S formed by decompn. of BaS by HCl . To obtain white BaCl_2 free from PbS it is best to boil with com. concd. HCl , which transforms PbS into PbCl_2 and dissolves it; BaCl_2 remaining undissolved. After this treatment, chem. pure BaCl_2 can be obtained by crystn. from H_2O .

BERNARD NELSON

Utilization of crude magnesium sulfate for the manufacture of Glauber salt. V. P. IL'INSKII AND G. S. KLEBANOV. Gos. Institut Priklad. Khimii. *J. Chem. Ind. (Moscow)* 5, 3-10(1928).—Glauber salt is obtained by cooling aq. solns. contg. a mixt. of MgSO_4 and NaCl : $\text{MgSO}_4 + 2\text{NaCl} \rightleftharpoons \text{MgCl}_2 + \text{Na}_2\text{SO}_4$. Mixed salts obtained by evapn. of salt lakes contg. MgSO_4 , and even straight lake water, can be utilized for this purpose. To det. the conditions at which the purest Na_2SO_4 can be obtained at the best yields, the authors tried using artificial mixts. having the following compns.: I: MgSO_4 89.89%, NaCl 10.11%; II: MgSO_4 78.46%, NaCl 21.54%; III: MgSO_4 67.83%, NaCl 32.17%; IV: MgSO_4 59.20%, NaCl 40.80%; V: MgSO_4 49.55%, NaCl 50.45%; VI: MgSO_4 39.60%, NaCl 60.40%; VII: MgSO_4 31.10%, NaCl 68.90%; VIII: MgSO_4 20.00%, NaCl 80%; IX: MgSO_4 10.35%, NaCl 89.65%. Various concns. and temps. of cooling, and duration of freezing-out were tried on these mixts. Curves showing compns. of the ppts. obtained under different conditions are given for solns. satd. with these mixts. at 18° to 19° . The solid phases obtained by freezing at 0° , -5° , -10.5° , -15.6° had the following compns. in g. per 100 g. of soln.:

		0°	-5°	-10.5°	-15.6°
I	$\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$	12.72	15.54	19.28	Frozen solid
II	$\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$	12.41	15.78	19.32	
	$\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$	—	—	5.05	
III	$\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$	12.75	14.98	16.48	
	$\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$	14.03	16.42	12.10	
IV	$\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$	10.20	12.10	10.25	10.03
	$\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$	20.05	21.70	28.40	28.82
V	$\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$	23.15	28.10	31.05	32.7
VI	$\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$	23.04	26.00	27.90	28.90
VII	NaCl	—	0.12	0.86	1.62
	$\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$	18.80	21.18	22.35	22.59
VIII	NaCl	—	—	0.83	1.53
	$\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$	10.62	12.54	13.51	14.00
IX	NaCl	—	—	0.82	2.69
	$\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$	3.43	5.61	5.93	6.82

I gives pure $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ at all temps. Mixts. V and VI give pure $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ at all temps. By diln. of these solns. pure Glauber salt may be obtained at any temp. of cooling and with any mixt. except I. Thus, when cooling to 0° the percents of H_2O (first figure) to be added to the above solns. to obtain a ppt. of pure $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ (second figure) are as follows: II: 15.01, 1.15; III: 9.73, 12.94; IV: 50.04, 19.28; V: 8.15, 22.05; VI: not tried; VII: 5.58, 18.03; VIII: 5.10, 10.24; IX: 5.00, 3.60. The amts. of H_2O to be added when operating at -5° , -10.5° , and -15.6° are also given, as well as the quantities of pure Glauber salt obtained under these conditions. Glauber salt crystallizes quickly; prolonged freezing is therefore unnecessary, but it is necessary to add a crystal of Glauber salt to create centers of crystn.

BERNARD NELSON

Graphite, its occurrence and importance. W. LANDGRAEBER. *Montan. Rundschau* 20, 223-4(1928).—The great importance of graphite in modern life is emphasized and many of its uses are enumerated. The location of a no. of deposits of graphite in European countries and in N. America, dates of starting mining and qualities of graphite obtained are given. Common impurities in natural graphite are silicates, Fe, clay, mica and iron pyrite. The different processes, crushing and grinding followed by direct calcining at 400° to 500° in a revolving furnace, or concn. by flotation using brown coal-tar oils and then heating, or wet grinding and sepn. in shaking settling chambers

or by flotation and roasting, which are used to purify the raw graphite, are outlined and their relative advantages stated. The newer electrothermic method of producing in a sealed furnace a 99% clean graphite is mentioned.

Concentrating graphite in Southern California. W. G. HUBLER. *Eng. Mining J.* 125, 1059-60(1928).—Discussion of operations at the Standard Graphite Corp. mill. A flow sheet is included.

Extraction of bromine or iodine from water by solvents. B. G. PANTLEIMONOV. *J. Chem. Ind. (Moscow)* 4, 713-9(1927).—The best com. conditions of extg. Br or I dissolved in H_2O by means of kerosene, sp. gr. 0.82, were investigated. The aq. Br solns. contained 0.32-0.97% Br. The extg. power of kerosene for Br is great. When operating in direct sunlight a single treatment absorbs all the Br; in darkness fresh kerosene usually leaves 5-10% unextd. By repeated treatment of Br- H_2O with kerosene in darkness only a trace of free Br is left behind. I is extd. completely in a single operation. The extd. halogens partly dissolve in kerosene, partly form with it addn. products, and partly give rise to substitution derivs. with simultaneous formation of HBr at the expense of the nascent H. HBr thus formed remains in water, but represents no loss, for it is easy to liberate Br from it. Br dissolved in kerosene can be extd. from it very easily by treatment with alkalies, most of the Br being transformed into NaBr, a small portion forming NaBrO₃. When using CaO bromide of lime is obtained, and it is perhaps best to obtain Br in this form, since it is most convenient for shipping, and since lime bromide gives off Br very easily by the action of acids. The use of $NH_3 \cdot H_2O$ for extg. Br from kerosene solns. is not recommended, as it removes less than NaOH and moreover has a greater tendency to form stable emulsions with kerosene. Stable emulsions are often formed also with NaOH, particularly if the kerosene contains much combined Br. These emulsions are broken up without difficulty by centrifuging. To recover the Br. combined with kerosene is not so easy. By distg. the brominated kerosene the most volatile fraction (b. up to 110°) contains almost no Br and can be used again for extg., but to sep. the Br from the rest of kerosene chem. treatments are not effective and it is best to soak lime or soda-lime with this kerosene and to burn the latter, thus obtaining bromide of lime, the loss of Br amounting to only 1 to 5%. The proportion in kerosene of free, dissolved Br to that of combined Br was also studied. The data obtained form the basis for an application for a patent. The length of time of keeping kerosene after extn. has no influence on the transformation of free Br to combined Br. Increase of temp. of treatment decreases the amt. of dissolved Br and increases the combined Br. The most important factor is light. When operating in direct sunlight all absorbed Br combines with kerosene, the only Br remaining in H_2O being that combined with H. When operating in darkness several extns. are necessary, and the percent of free, dissolved Br increases by repeated extns., whereas the percent of chem. combined Br decreases. Kerosene does not begin to act as solvent of free Br until part of it first combines with some Br. Thus fresh kerosene combines with four times as much Br as it dissolves free Br, but when kerosene gradually becomes satd. by combining with Br, five times more Br dissolves than combines. It is advisable to use brominated or chlorinated kerosene, and not pure kerosene, so as to ext. free Br and to use the same kerosene repeatedly for further extns. Oversatn. of kerosene by dissolved Br decreases its extg. capacity, so that free Br should be removed from it from time to time. Instead of kerosene petroleum ether can be used for Br extn. I is extd. in the same way as Br.

BERNARD NELSON

The importance of carbon monoxide as a reducing agent in the production of hydrogen by the contact method. A. LOSHKAREV. *Oil and Fat Ind. (Russia)* No. 6, 22-5(1926); *Chem. Zentr.* 1, 2936-7(1927).—In the reduction of the Fe contact agent used for producing H_2 from H_2O in hardening fats, the CO of the water gas, with which reduction of the oxidized Fe is accomplished, enters into reaction much sooner than H. Accordingly, a disproportionately great quantity of CO is consumed, compared with the proportions of CO and H in water gas. The greater the proportion of CO in the water gas, the sooner is the reaction completed. It is recommended therefore that the CO content be increased artificially, either by partial injection into the water-gas producer of gas already used for the reduction, which contains CO₂, or else by the addn. of O₂ to the air for combustion. Fuel with the smallest possible S content should be used, since otherwise part of the O₂ of the air for combustion is rendered useless. A table shows the compn. of water gas before and after the reduction, and the relatively great consumption of CO.

C. C. DAVIS

Factors affecting the world nitrogen situation. HARRY A. CURTIS. *Yale Univ. Chem. Met. Eng.* 35, 469(1928).

E. H.

Production of pure sulfur and ammonium sulfate from crude impure sulfur ob-

tained from coke-oven gas. W. GLUUD, R. SCHÖNFELDER AND W. RIESE. *Ber. ges. Kohlentech.* (Dortmund-Ewing) 2, 118-41.—See *C. A.* 22, 482. C. C. DAVIS

The purification by simple distillation of crude sulfur obtained from coke-oven gas. A second method for the utilization of crude sulfur. W. GLUUD, R. SCHÖNFELDER AND W. RIESE. *Ber. ges. Kohlentech.* (Dortmund-Ewing) 2, 142-7; *Chem. Zentr.* 1927, II, 198.—If the quantity of crude S deposited according to the process of G. and S. is small, its purification according to the process of G., S. and Riese (cf. preceding abstr.) is not advantageous. In such cases, purification by simple distn. is practicable. A small quantity of FeS is formed, which can be converted into Fe₂O₃ by combustion. Calcs. of the economy of the processes are included. C. C. DAVIS

Sulfur and motive power. LUIGI CANTIMORRI. *Giorn. chim. ind. applicata* 10, 182(1928).—Comments on a paper by Buogo (cf. *C. A.* 22, 2641), which show that there are several difficulties involved in the general adoption of the proposed method of treatment, one of the most difficult of which is the fact that treatment with superheated steam does not remove all S, a considerable proportion remaining in the gang. C. C. DAVIS

Recovery and utilization of sulfur dioxide in the extraction of sulfur. ALBERTO GALLETTI DI S. CATALDO. *Atti. congresso naz. chim. pura applicata* 2, 708-18(1926).—In the extn. of Sicilian S the common practice is to burn the ore, the heat evolved being sufficient to melt the greater part of the S, which is run off free from impurities. C. recommends utilization of the SO₂ evolved to form H₂SO₄ and dissolve out the carbonates of the raw material, leaving a product much richer in S. The process is particularly applicable to ore rich in carbonates, but is not so satisfactory when there is much siliceous gang present. The residue from a carbonate ore originally contg. 30.49% S had a S content of 90% after extn. with H₂SO₄. L. T. FAIRHALL

A Pacific Coast setting for industrial research. PAUL D. V. MANNING. *Chem. Met. Eng.* 35, 460-2(1928).—The new lab. and the operations of the Celite products Co., producers of diatomaceous earth and manufs. of Sil-O-Cel, are described. E. H.

New developments in the production of American gas black. WERNER LÖSCH. *Kautschuk* 1928, 127-8.—A review and discussion. C. C. DAVIS

Determinations of the density of different kinds of carbon black. LOTHIAR HOCK. *Kautschuk* 1928, 140.—The d. was detd. by removing the adsorbed air *in vacuo* and then utilizing the pycnometer method with toluene. The av. d_4^{23} of 4 kinds of oil blacks was 1.762 (varying from 1.7515 to 1.7690) and the av. d_4^{23} of gas black (Arrow) was 1.770 (varying from 1.7530 to 1.803). C. C. DAVIS

Fuller's earth from New Zealand. ANON. *Bull. Imp. Inst.* 26, 148-51(1928) --- Comparison of fuller's earth from Whangarei, N. Auckland district, with 3 samples of good-grade English earth showed the N. Z. earth to be superior for the bleaching of neutralized cottonseed oil and about equal to the English earths for bleaching neutralized soy-bean oil. Igniting the earths 4 hrs. at 600° did not affect their action on cottonseed oil, but greatly improved the bleaching action of the N. Z. earth toward soy-bean oil. A. PAPINEAU-COUTURE

Adhesives and adhesion; pure chemical substances as adhesives. JAMES W. MCBAIN AND W. BELL LEE. Stanford Univ. *J. Phys. Chem.* 32, 1178-84(1928); cf. *C. A.* 21, 991; 22, 142.—Observations on the adhesive property of pure compds. are extended by measurements on a no. of org. compds., including 5 highly purified carbinols of the type *l*-R₁EtCHOH, where R is *n*-decyl, un-, do-, tri- and penta-decyl. As might be expected, these compds., which are good lubricants, are poor adhesives. Measurements on the tension strengths were also made on thin layers of cetyl alc., elaidic, cerotic, stearic, dihydroxystearic and cinnamic acids, *p*-nitroaniline, β -naphthol, resorcinol, catechol, *p*-toluidine, azelaic and uric acids, S, rosolic acid, malachite green G and aurin. The breaking points varied from 120-1000 lb. per sq. in. for Ni and steel surfaces, and were usually somewhat lower for Cu, Al and duraluminum. The adhesive strength of aurin, the formula of which is related to triphenyl-carbinol, previously reported as a good adhesive, was found to be as high as 1000 lb. per sq. in. between Ni plates. "Overheated" glycolic acid which, like shellac, contains a lactide structure, has a tension strength of 2200 lb. per sq. in. between Ni surfaces. The joints, when not overloaded, are stable for as long as a month. In all cases the fracture takes place in the adhesive itself and not at the interface. Tests on fused coumarin between walnut surfaces show that the liquid wets the wood and that the shearing strength may be as high as 1 ton. H. F. JOHNSTONE

Detection of phosgene in chemical fire extinguishers. E. GLASER AND S. FRISCH.

Z. angew. Chem. 41, 263-5(1928).—Most chem. fire extinguishers contain CCl_4 , which on thermal decompn. in presence of O_2 produces phosgene. A no. of accidents have occurred from this cause, and it has been claimed that the addn. of ethylene dibromide reduces the formation of phosgene. The authors found that by passing a mixt. of dry air and CCl_4 vapor through a 30-cm. tube heated to 250° and charged with anhyd. FeCl_3 and pumice, phosgene up to 45% of the theoretical yield is obtained. The resultant gases were freed from Cl and passed into aq. aniline, and the ppt. of diphenylurea was weighed. The reaction proceeds up to equil. and the residual gases freed from phosgene can be further oxidized; methyl bromide, if present, increased the yield of phosgene, but ethylene dibromide reduced it. The compns. of solns. in various fire extinguishers are given, and the use of those containing CCl_4 condemned as dangerous.

B. C. A.

Methods of examination of fine pearls and of cultivated pearls. J. GALIBOURG AND F. RYZIGER. *Rev. optique* 6, 97-133(1927); *Chimie et industrie* 19, 874(1928).—A description of the formation and characteristic structure of fine (or "spontaneous") pearls and of cultivated pearls, and of the methods used in practice to differentiate them. Cultivated pearls contain a spherical nucleus of mother-of-pearl, a few mm. in diam., the presence of which is detected by means of the following detns.: d, structure, transparency to light rays, x-ray interference, propagation of light in the body of the pearl. The 5 detns. are based on different properties of the material constituting the pearl, and the results of the different detns. should be interpreted in conjunction with one another, it being unsafe to draw conclusions from the results of only 1 detn.

A. PAPINEAU-COUTURE

Injurious field rats of Lower Sind and their extermination. P. V. WAGLE AND GUL MAHOMED. *Dept. Agr. Bombay, Bull.* 138, 34 pp.(1927).—Raw sugar, coconut oil and aniseed oil appeared to detract from the value of wheat bran, rice and rice flour as baits for the Sind mole rat (*Gnomys indicus*). Strychnine-HCl and white As were more effective poisons than BaCO_3 , while plaster of Paris and a proprietary P prepn. were not effective. Ingestion of 0.1 grain of strychnine-HCl caused death within 12 hrs., and 0.2 grain of white As was fatal in 36 hrs.; while 1.2 grains of BaCO_3 was fatal in 48 hrs. In field expts. strychnine-HCl was successful in 35-65% of the trials when the poison was used on meat and whole wheat, but white As and BaCO_3 gave very poor results. Excellent results were obtained with CS_2 when the vapors were pumped into the burrows by means of a special vaporizer. S fumes and tobacco smoke also gave good results, but gasoline was not effective. Ca(CN)_2 dust gave as good results as CS_2 and at a lower cost. Fumigation should be done between the middle of August and the first of November as the burrows are relatively short during this period.

K. D. JACOB

Report on alkali, etc., works in England and Wales (BAILEY) 13. Apparatus for leaching caliche with circulating liquid in successive stages (U. S. pat. 1,678,787) 1. Catalytic apparatus [for oxidizing NH_3] (U. S. pat. 1,678,778) 1.

KEGHEL, MAURICE DE: *Traité général de la fabrication des colles, des glutinants et matières d'apprêts*. Paris: Gauthier-Villars et Cie. 715 pp. F. 125 (paper). Reviewed in *Chimie et industrie* 19, 976(1928).

Fluorine compounds. ALBERT F. MEYERHOFER. Fr. 632,840, Feb. 22, 1927. An app. is described for the decompn. by heat of complex F compds. such as the fluosilicates of Na, K, Ba, etc., in which a gas such as air, steam, H, or combustion gases is passed over the heated material to reduce the partial pressure of the volatile fluoride disengaged.

Hydrocyanic acid. MORTIMER J. BROWN and EARLE A. HARDING (to Roessler & Hasslacher Chemical Co.). U. S. 1,680,662, Aug. 14. Crude cyanide-contg. material such as crude NaCN is mixed with an acid salt, e. g., NaHCO_3 , and water and the mixts. are agitated under a pressure less than atm. pressure to effect boiling of the water at a temp. below that at which the HCN would polymerize; the water vapors evolved serve to sweep evolved HCN from the reaction mass. An app. is described.

Hydrocyanic acid. STICKSTOFFWERKE GES. (to A. R. Frank and N. Caro). Brit. 282,379, Dec. 17, 1926. HCN is formed by passing NH_3 and CO at a temp. of about $700-800^\circ$ over oxides of the alk. earths, including MgO, or over compds. such as carbonates or hydroxides which yield oxides on heating, or over the cyanamides which are the first product of the reaction. Other gases such as H and N may be present as found in industrial gas mixts. Metals which tend to decomp. NH_3 or HCN are excluded or their action is prevented by adding sulfide compds. or water.

Apparatus for continuous production of nitric acid or hydrochloric acid and sodium bisulfate. GIUSEPPE GUADAGNI. U. S. 1,680,019. Aug. 7. A reaction chamber is mounted within a furnace so that combustion gases may circulate freely all around the chamber; a const.-level discharge pipe for the reaction residue and special supply conduits for admission of the reagents and outlet pipe for the gaseous product provide for continuous operation.

Concentrating nitric acid. H. FRISCHER. Brit. 281,691, Dec. 6, 1926. Concn. is effected by heating dil. HNO_3 admixed with a water-absorbent substance such as H_2SO_4 , in successive stages at increasing temps. A steam-jacketed column still is described which may be heated by superheated steam.

Phosphoric acid. HERMANN LANG (to I. G. Farbenind. A.-G.). U. S. 1,680,625, Aug. 14. See Can. 273,514 (C. A. 21, 3715).

Phosphoric acid. JULIUS KERSTEIN. Fr. 634,117, May 10, 1927. Phosphoric acid is made by passing HCl over phosphorite at a red heat. SiO_2 is preferably added to prevent fusion.

Phosphoric acid and calcium compounds. FRANS G. LILJENROTH. Fr. 633,828, May 3, 1927. Crude phosphates contg. Ca are treated by a wet process to recover the lime as well as H_3PO_4 . In an example crude phosphate is suspended in water and gaseous SiF_4 is passed in, which liberates H_3PO_4 and forms CaF_2 . The H_3PO_4 is removed, and SiO_2 , clay or aluminous material is added and the mixt. heated in a furnace, whereby SiF_4 is re-formed and a cement aggregate is obtained. Instead of CaF_2 , CaSO_4 may be formed.

Phosphoric acid and calcium carbonate. FRANS G. LILJENROTH. Fr. 633,866, May 4, 1927. In treating Ca phosphates to obtain H_3PO_4 and recover the Ca, CaSO_4 is formed and NH_3 and CO_2 are passed in to form $(\text{NH}_4)_2\text{SO}_4$ and CaCO_3 , the latter being used for making cement. The $(\text{NH}_4)_2\text{SO}_4$ formed is used to sep. more lime from the phosphate.

Sulfur dioxide from hydrogen sulfide. HANS BAHR (to I. G. Farbenind. A.-G.). U. S. 1,678,630, July 31. In purifying gases contg. H_2S oxidation of the latter is effected by use of a mixt. of metals, one of which such as Fe, Ni or Cu has the property of binding S and another such as V or W the property of promoting oxidation.

Storage and transportation of acids in steel drums. JAMES H. GRAVELL. U. S. 1,678,775, July 31. Action of acids such as H_2SO_4 on steel containers is inhibited by use of As or Sn or other suitable metal "below Fe and above Hg in the electromotive series" together with an "acid-regulator" such as a distillate contg. pyridine bases for forming a protective coating on the steel.

Synthetic ammonia. ROLAND E. SLADE and KENNETH GORDON (to Atmospheric Nitrogen Corp.). U. S. 1,679,792, Aug. 7. In order to remove NH_3 from compressed synthesis gases, the gases are scrubbed at high pressure with an aq. medium in such quantity as to form a soln. contg. about 50-70% NH_3 .

Ammonia synthesis. HANS SVANOE (to The Ammonia Corp.). U. S. 1,678,964, July 31. The reaction is initiated by a catalyst in the presence of excess H to provide high heat cond. and control the reaction and there is subsequently introduced another gas contg. supplemental N to lower the heat cond. and render the reaction more active.

Apparatus for ammonia synthesis or similar catalytic reactions. SOC. L'AIR LIQUIDE, SOC. ANON. POUR L'ÉTUDE ET L'EXPLOITATION DES PROCÉDÉS G. CLAUDE. Brit. 282,658, Dec. 24, 1926. In app. of the type described in Brit. 268,721 (C. A. 22, 1444), reacting gases are circulated through the inner catalyst-contg. receptacle in indirect contact with the catalyst, in excess of the quantity which will pass into direct contact with the catalyst, and the excess is discharged to the outside of the app. after heating. Various structural details are described.

Catalyst "compact." WILLIAM SCHULTZE (to Atmospheric Nitrogen Corp.) U. S. 1,680,807, Aug. 14. A catalyst suitable for use in synthesis of NH_3 , which is porous to the gases to be catalyzed, is formed of hard granules of MgO carrying Fe oxide or other catalyst material which does not readily cohere, substantially free from added adhesive agents; the granules are caused to cohere sufficiently by compression into tablets that the catalyst is not disintegrated under the conditions of the reaction in which it is used.

Alkali metal hydroxides. LEO P. CURTIN. U. S. 1,678,767, July 31. An aq. suspension of PbO is agitated while adding an alkali metal sulfide such as that of Na and the supply of sulfide is regulated to avoid any substantial accumulation of sulfide ions in the soln.

Alkali iodates. I. G. FARBENIND. A.-G. Fr. 633,994, May 6, 1927. Alkali iodates are prepd. by allowing O to act on a fused mixt. of an alkali hydroxide and alkali

iodide, or O is allowed to act on an alkali iodide at about 600° and at a pressure above 100 atms., or alkali iodide is oxidized in aq. soln. at a temp. above 100° and at increased pressure, with or without a catalyst.

Persalts, etc. HENKEL ET CIE., GES. Brit. 282,302, Dec. 24, 1926. Solns. of the reagents used in prepg. persalts and percompds. (e. g., borax, NaOH and Na₂CO₃ used in making perborates or percarbonates, K₂SO₄ and Na₃PO₄ used for making persulfate or perphosphate, and H₂SO₄, water, etc., used in making H₂O₂) are purified by treatment with silica gel to ppt. heavy metals which otherwise might cause catalytic decompn. of the percompds. The solns. may be boiled with silica gel and afterward crystd.

Soluble phosphates. F. G. LIJENROTH. Brit. 282,619, Dec. 23, 1926. Sol. phosphates are prepd. by leaching crude Ca phosphate with a smaller proportion of H₂SO₄ than that "corresponding to the Ca" in the crude material to give mono-Ca phosphate and free H₃PO₄. Ca is simultaneously or subsequently pptd. by alkali or NH₄ sulfate, leaving sol. phosphate in soln. The filtered soln. is neutralized, preferably with NH₃, and evapd. (NH₄)₂SO₄ and CaCO₃ are formed from the CaSO₄ by CO₂ and NH₃. An excess of KCl or K₂SO₄ may be added and if K phosphate is desired KOH, K₂CO₃ or KCl may be used as a neutralizing agent.

Double silicates. F. SINGER Brit. 282,402, Dec. 17, 1926. Double silicates similar in type to natural plagioclase compds. are made by reacting on the oxides, carbonates, sulfates, silicates or aluminates of bivalent metals such as Mg, Ca, Ba, Sr and bivalent Fe (or their mixts.) with alumina and silica at temps. below the fusion point of the mixt. (preferably at least 50° below this point). The alumina may be introduced in the form of oxide, hydroxide, silicate, double silicate or aluminate, and the silica as quartz sand, alk. earth silicate, Al silicate or double silicate. The products are resistant to HF and other acids and possess good insulating properties, and may be used for making muffles, filters, insulators, "stones" or abrasives.

Zirconium compounds. FRIEDRICH RUSBERG and PAUL SCHMID (to Rhenania-Kunheim Verein Chemischer Fabriken A.-G.). U. S. 1,681,195, Aug. 21. A Zr ore such as one contg. 75% ZrO₂ and 15% SiO₂ is mixed with an earth alkali such as CaCO₃ and with CaF₂ or other alk. earth metal halide, without addn. of any carbonaceous material, the mixt. is heated to a sintering temp. and the sintered product is treated with a quantity of HCl insufficient to dissolve the basic constituents of the product; the soln. is sepd. and HCl is added to it, to prep. it for crystg. zirconyl chloride.

Alumina and alkali metal carbonate. FRITZ ROTHE and HANS BRENEK (to Rhenania Verein Chemischer Fabriken A.-G.). U. S. 1,680,066, Aug. 7. Aluminous minerals such as bauxite are mixed with alkali metal sulfate and the mixt. is heated to incandescence in the presence of steam at a temp. of at least 1100° while avoiding any reduction in the mixt., in order to form aluminate suitable for further treatment with H₂O and CO₂.

Alumina. JEAN-CHARLES SEAILLES. Fr. 634,430, Sept. 18, 1926. See Brit. 277,697 (C. A. 22, 2642).

Aluminum sulfate. ROY M. MEIKLEJOHN (to General Chemical Co.). U. S. 1,679,366, Aug. 7. An aluminous material such as clay or bauxite is treated with H₂SO₄ of such strength (suitably about 50%) that substantially complete decompn. is effected and a basic product is formed, while maintaining the temp. at about 178° to maintain the reacting substances in liquid condition.

Carbon disulfide. I. G. FARBENIND. A.-G. Brit. 282,049, Dec. 13, 1926. In prepg. CS₂ as described in Brit. 237,716 (C. A. 20, 1696), a superheater for S vapors is positioned in the furnace chamber which contains the reaction chamber contg. C.

Chromium oxide and chromium hydroxide. I. G. FARBENIND. A.-G. Fr. 633,956, May 5, 1927. Cr(OH)₃ and Cr₂O₃ are prepd. by treating solns. of chromates with org. reducing agents such as sawdust, molasses, lignite dust, or residual dyes from the manuf. of cellulose, etc., at a temp. above 100° and preferably under pressure.

Lead carbonate. STANLEY C. SMITH. Fr. 633,813, May 3, 1927. See Brit. 272,053 (C. A. 22, 1658).

Lead chloride. NORDDEUTSCHE CHEMISCHE FABRIK IN HARBURG. Brit. 282,306, Aug. 8, 1927. PbSO₄ is treated with a soln. of a chloride under pressure at a temp. above 100°, e. g., boiled with a concd. soln. of NaCl for 10–15 min. at 140–150° under 4–5 atm. pressure.

Crystallization apparatus for potassium dichromate, barium chloride, etc. WALTER SEMEL (to I. G. Farbenind. A.-G.). U. S. 1,679,055, July 31. A crystg. vessel is provided with a centrally located raised portion of its bottom so that by rocking the

vessel liquid can be caused to flow from one lateral chamber of the vessel to another while restraining movement of crystals.

Recovering combined nitrogen from crude calcium cyanamide. GUY H. BUCHANAN and PALMER W. GRIFFITH (to American Cyanamid Co.). U. S. 1,678,721, July 31. "Lime nitrogen" 1 is mixed with water 1-4 parts, the soln. is filtered, and the sepd. solids are digested in an autoclave with addnl. water, to recover addnl. N as NH_3 .

Hydrating lime. CHRISTIAN P. BERG. U. S. 1,679,149, July 31. A mixt. of lime and water is held in a curing zone and a substantial portion of the water is drained off; addnl. water is passed through the mixt., and the putty thus cured is removed from the app. (details of which are described).

Hydrogen peroxide. J. D. RIEDEL A.-G. Fr. 634,195, Feb. 5, 1927. In making H_2O_2 by the distn. of solns. of persulfates, use is made of a soln. which contains a mol. of H_2SO_4 for each mol. of persulfate and sulfate.

Hypochlorite composition. JAMES D. MACMAHON (to Mathieson Alkali Works). U. S. 1,678,987, July 31. A dry mixt. which is suitable for making solns. comprises anhyd. Na_2SO_4 and $\text{Ca}(\text{OCl})_2$. H_3BO_3 or NaHCO_3 also may be added.

Bleaching powder. JAMES T. CONROY, ALFRED LAMBLE and JOHN J. LATHAM (to United Alkali Co., Ltd.). U. S. 1,680,087, Aug. 7. See Brit. 246,000 (C. A. 21, 479).

Highly activated carbon. SOC. POUR L'EXPLOITATION DES PROCÉDÉS ÉDOUARD URBAIN. Fr. 634,415, Sep. 16, 1926. Highly activated carbons are made from vegetable substances such as peat, vegetable ivory, bark, moss, lichen, or algae, which contain, besides cellulose, vegetable matter capable of being transformed into carbohydrates or of forming with H_3PO_4 a gel, such that after division into grains of the appropriate size the matter takes on, when dried and calcined, a very high mechanical resistance.

Extraction of lead. CREM. AND MET. CORP., LTD. and STANLEY C. SMITH. Fr. 633,810, May 3, 1927. In a process for extracting Pb from ore wherein PbCl_2 is suspended in a soln. of NH_3 , PbCO_3 is obtained without the basic chloride by passing in CO_2 at such a speed that the presence of carbonic acid is avoided as far as possible.

Sulfur. WILLIAM H. BENTLEY (two-thirds to John Riley & Sons, Ltd). U. S. 1,680,079, Aug. 7. See Brit. 252,938 (C. A. 21, 2537).

Metal catalysts. I. G. FARBERIND. A.-G. Brit. 282,410, Dec. 14, 1926. Metals such as Ni, Co or Cu are pptd. from ammoniacal soln. by H, preferably under pressure and in the initial presence of catalytic metal, with or without use of a carrier such as kieselguhr.

Composition for producing heat by chemical reaction. CHARLES E. LYON (to Hooker Electrochemical Co.). U. S. 1,679,432, Aug. 7. A compn. suitable for generating heat on the addn. of H_2O comprises an alkali metal hydroxide and a salt which reacts with the hydroxide with evolution of heat, e. g., a mixt. of NaOH 90 and Na Al chloride 10%.

Apparatus for evaporating brine. METALLWERKE VORM. J. ADERS A.-G. Brit. 281,726, Dec. 4, 1926. In a plant comprising a vacuum evaporator and a preheater, deposition of crystals between the evaporator and heater is prevented by forcing the brine rapidly through a narrow barometric tube. Various structural features are described.

Furnace for calcining soda. DWIGHT R. MEANS (to Pittsburgh Plate Glass Co.). U. S. 1,679,486, Aug. 7. A covered calcining pan is arranged to discharge the material at one end and is provided with agitators; a rotary furnace is placed to receive the material as discharged from the pan. Combustion gases from a furnace beneath the pan pass along the shell of the rotary furnace.

Dispersing agent. FRIEDRICH FELIX (to Soc. anon. pour l'ind. chim. à Bâle). U. S. 1,680,778, Aug. 14. The resinous residue which is obtained as a by-product in the rectification of benzaldehyde is treated with sulfonating agents such as H_2SO_4 contg. SO_3 . The product thus formed is suitable for use as a dispersing agent in forming emulsions.

Urea-formaldehyde condensation products. F. SCHMIDT. Brit. 281,993. Urea- CH_2O condensation products are formed in the presence of "carrier substances" or mixed with such substances prior to dehydration and then dehydrated while being kept in motion. Among the "carrier substances" which may be used are: casein, cellulose and its derivs., natural and artificial resins, polymerized vinyl esters, and fibrous or amorphous fillers such as wood meal, peat meal or alumina. Other substances forming resinous products with CH_2O such as urethan, aniline, benzanilide and other anilides, *p*-toluenesulfonamide and other amides or PhOH may be used with the urea, and gelatinizing and softening agents, coloring substances, etc., also may be added.

Urea-aldehyde condensation products. SOC. ANON. POUR L'IND. CHIM. A BALÉ. Brit. 281,717, Dec. 4, 1926. Condensation products of urea with an aldehyde such as CH_2O , having a porous structure, are prepd. by first condensing the materials to a stage beyond the methylol-urea phase, then polymerizing in the presence of a catalyst such as an acid or salt and finally removing the catalyst (suitably by washing—after neutralization in the case of an acid—or by electroösmosis). The water usually present may be replaced by alc. or other solvent, and softening, filling and coloring agents may be added either during the condensation or to the finished product. Various details and examples are given.

Composition for making molded articles. HARRY S. SNELL (to Western Elec. Co.). U. S. 1,678,713, July 31. A material which may be used as a dielectric is formed by the condensation of furfural and an insol. proteinate such as Al soy-bean or milk caseinate.

Artificial substances. CARL GUSTAF ALBERT LUNDBERG. Fr. 634,120, May 10, 1927. See Brit. 271,076 (C. A. 22, 1659).

Plastic composition. OSCAR A. CHERRY and CLETUS F. CHOSA (to The Cutler-Hammer Mfg. Co.). U. S. 1,678,635, July 31. A molding compn. comprising asbestos or other relatively inert filler impregnated with a binder such as coal tar pitch, stearin pitch, gilsonite and S is incorporated with a small proportion of a halogen deriv. of S, e. g., S chloride and a phenolic compd. such as cresol which will react together to form addnl. binder.

Plastic compositions. I. G. FARBENIND. A.-G. Brit. 282,635, Dec. 23, 1926. Methylol compds. such as those of ureas are mixed with wood, lignin or other suitable fillers which have been impregnated with phenol, urea, thiourea or their derivs. or condensation products with aldehyde and the mixt. is hardened. Catalysts, buffer, casein, horn, yeast and aldehydes may also be added. The product may be used as an elec. insulating material.

Plastic material from peat. ISADORE S. MELLANOFF (to Kemikal, Inc.). U. S. 1,681,155, Aug. 14. A compn. which is suitable for molding is formed by the interaction of peat, an alk. material such as NaOH, a phenol and an aldehyde, e. g., PhOH and CH_2O .

Coloring plastic substances. I. G. FARBENIND. A.-G. Fr. 634,457, May 16, 1927. Plastic or plastifiable substances having a basis of celluloid or cellulose ester or ethers, or natural or artificial resins are colored by incorporating therein with or without org. solvents, Cr or Cu compds. of coloring matters, particularly *o*-hydroxyazo colors which contain also SO_2H , COOH or sulfamidic groups.

Adhesive material from soy beans. OTIS JOHNSON (to I. F. Laucks, Inc.). U. S. 1,680,264, Aug. 7. Soy beans are soaked in water at a temp. not exceeding about 70° , ground while moist, mixed with water and an alkali such as borax, NaOH or NaHCO_3 at a temp. not above about 70° ; juice is sepd. from the mass; oil is sepd. from the juice; a curdling agent such as a dil. acid is added to the oil-freed juice, and the curd is washed and centrifuged or otherwise treated to remove moisture. The product may be used in paints, calcimine, sizings, etc.

Composition for expansion joints. ALBERT C. FISCHER. U. S. 1,680,144, Aug. 7. Fibrous material such as excelsior and cork is mixed with tar, pitch or other suitable bituminous material while the latter is of a consistency below that at which it will sat. fibrous material.

Plaster bandages. JOHNSON & JOHNSON (Gt. Britain), Ltd. Brit. 282,243, Feb. 28, 1927. Plaster of Paris for use with open-mesh fabric is mixed with a bonding material such as that formed by boiling an aq. soln. of sugar and dextrin, or gum arabic or starch, and adding HOAc or other retarder of setting.

Refining graphite. STÉPHANE H. M. CHANIOT. Fr. 634,505, May 17, 1927. The mineral is treated by malaxage and flotation, fine bubbles of air being formed in the liquid which attach themselves to the particles of graphite previously oiled.

Coating objects. FÉLIX CLAIREAUX. Fr. 634,410, Sep. 15, 1926. The objects are dipped in a bath of melted gelatin, oil of turpentine and glycerol, and afterwards treated with CH_2O and dipped in a bath of petroleum jelly.

Binding agent for colors, varnishes, etc. JOHANN TENGLER. Fr. 634,275, May 12, 1927. See U. S. 1,660,851 (C. A. 22, 1498).

Coloring slate or other mineral materials. HARRY C. FISHER (to The Richardson Co.). U. S. 1,680,941, Aug. 14. Particles of crushed slate or other material are colored by forming on their surface a layer of a ferrite, which may be produced by use of CuSO_4 and FeSO_4 successively.

Composition for removing paint. H. L. LEASE. Brit. 282,549, Dec. 8, 1926. A

wax such as beeswax, paraffin or "earth wax" is used with an "unseparated" coal-tar light oil. C_6H_6 and an alc. such as "methylated spirits" may be added.

Printing-plates of celluloid. C. H. E. OGILVIE. Brit. 282,465, June 25, 1926. A design is applied to the surface of a celluloid sheet, in casein or other substance which will resist the action of a celluloid solvent, and the sheet is then treated with a solvent such as acetone to leave the design in relief.

Printing-surfaces. M. ULLMANN and F. ULLMANN GES. Brit. 282,474, Aug. 19, 1926. In producing printing-blocks for lithographic offset printing-machines, in which a sensitive layer, hardened by exposure, serves as the resist for the etching soln., and in which the etched surfaces serve directly as the carriers for ink, the metal is etched in a single operation, the plate then rinsed with water, dried, rolled up with a fat ink which adheres to the metal parts, and the colloid layer is removed with HCl and the block further prepd. for printing in the usual way. The sensitive layer is formed of a soln. of gelatin, $(NH_4)_2Cr_2O_7$, NH_3 and NH_4 formate. The etching soln. comprises a mixt. of halogen salts, preferably chlorides of Al and Fe, one of which etches the metal and the other of which serves to render the exposed colloid layer less sol.

Gluing, cementing and impregnation. SOC. CONSORTIUM FÜR ELEKTROCHEM. IND. G. M. B. H. Fr. 634,136, May 10, 1927. The various polymerization products of vinyl acetate obtained with or without catalysts are used for gluing, cementing and impregnating such as waterproofing.

Impregnating hats to prevent perspiration stains. OCTAVE BROTELLE. U. S. 1,680,852, Aug. 14. A sol. alk. saponif. agent such as Na_2CO_3 is used for impregnating that portion of hats of felt or other material which is adjacent the head of the wearer, to render stain-forming constituents of the perspiration inactive after coming in contact with the impregnated material.

Composition for impregnating shoe-stiffening fabrics. UNITED SHOE MACHINERY CORP. Brit. 281,771, Sept. 9, 1926. A thickened drying oil such as China wood oil polymerized to an "incipient gel" is used with other ingredients such as colophony, copal, montan wax, carnauba wax, lime, MgO and ZnO.

Stencil sheet. SHINJIRO HORII. U. S. 1,679,034, July 31. A suitable base of fibrous material such as yoshino paper is coated with a compn. comprising esters of polysaccharides and squalene, *e. g.*, a compn. formed from cellulose nitrate 10, EtOH 15, EtOAc 15, AmOAc 30, AmOH 10, petroleum benzine 20, squalene 20, naphthenic acid glycerides 5, olein 5 and stearin 5 parts. Cf. C. A. 22, 2819.

Separating diamonds from sedimentary rocks. TALBOTT H. FRANCE U. S. 1,679,857, Aug. 7. The material is heated to induce differences in expansion between the diamonds and their matrices and the heated material is then abruptly cooled, *e. g.*, by quenching in water.

Detergent. YOSHITARO KATAYAMA. U. S. 1,678,815, July 31. A compn. suitable for use on wood, metal or leather comprises an aq. decoction prepd. from wild rhubarb root 95, cedar oil 1 and a strong alum soln. 4%.

Composition for filling roots of teeth. ERIK G. HEDSTRÖM. U. S. 1,678,940, July 31. See Brit. 276,526 (C. A. 22, 2447).

Demineralization of bones. GÉLATINES HASSELT & VILVORDE. Fr. 634,361, May 13, 1927. Bones are treated with an aq. soln. of H_3PO_4 and the leaching liquors are treated with milk of lime. The necessary H_3PO_4 may be obtained by treating a part of the leaching liquors with H_2SO_4 .

Acoustic disks. POLYPHONWERKE A.-G. Fr. 633,790, May 3, 1927. To obtain disks of artificial resin or cellulose compds. entirely free of solvent, old or newly formed disks are ground up and freed from volatile matter in a vacuum, after which gum lac, artificial resin, or similar plastifying substances are added and the disks are formed in the usual manner.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

New views on the chemical constitution of glass. O. KNAPP. *Chem. Rundschau Mitteleuropa u. Balkan* 1927, Sept. 30, 155; *J. Soc. Glass Tech.* 12, No. 45, 4.—Glass was considered most probably to be, chemically, a silicate in mutual soln. in free acids and bases. From the physicochem. point of view it was suggested that those substances were to be considered as glasses which possess at the temp. prevailing below the equil. curve a liquid phase corresponding with the field above the curve. H. G.

Contribution on the subject of the constitution of glasses. HERBERT SCHONBORN. *Sprechsaal* 61, 99–101, 117–20(1928).—The thermal coeff. of expansion and the elec. cond. were detd. and are given for glasses of various compns. which were quenched from different high temps. The correlation between the detd. phys. constns. and the quenching temp. permits the drawing of conclusions on the mol. constitution of the glasses. In addn. the contractions were measured which quenched rods of glass undergo at higher temps. and the dependence of time and the temp. at which the tests were made are expressed by formulas. Phenomena of inertia noted in viscosity measurements are given.

R. A. HEINDL

Elastic constants of glass. EDGAR P. PERMAN AND WM. D. URRY. *Proc. Phys. Soc. London* 40, 186–92(1928).—The coeff. of compressibility, bulk modulus, modulus of rigidity, Young's modulus, and Poisson's ratio were measured at intervals of 10° from 30° to 80° . The glasses used were standard Jena 16^{III} and a typical soda glass of compn. 66.00% SiO₂, 4.99% Al₂O₃ + Fe₂O₃, 7.49% CaO (+SrO), 13.05% Na₂O, 8.30% K₂O. The measurements were made by 2 methods. In method I a long cylindrical bulb with a capillary sealed on one end was filled to the mark with water and subjected to longitudinal compression. The app. was immersed in a thermostat and a mass of 5000 g. was used as the compressing force. The rise of the capillary was measured with a cathetometer. In method II the glass piezometer bulb was placed inside a steel cylinder contg. Hg, the capillary of the bulb extending through the rubber packing of the cylinder. The bulb was filled with water and the rise of the capillary observed as above, when pressure was applied to the Hg. The results are expressed mathematically in the table.

	Soda Glass	Jena 16 ^{III}
$10^{-8} \times$ coeff. of compressibility per atm.	238.0 + 0.185t	220.6 + 0.28t
$10^{-11} \times$ bulk modulus (C.G.S.)	4.241 – 0.00296t	4.577 – 0.0051t
Poisson's ratio	0.2207 – 0.00012t	0.2475 – 0.00068t
$10^{-11} \times$ modulus of rigidity (C.G.S.)	2.99 – 0.002t	3.29 – 0.0036t
$10^{-11} \times$ Young's modulus (C.G.S.)	7.27 – 0.005t	7.97 – 0.009t

A. E. BADGER

The weathering and durability of glass. KIYOSHI UEDA. *Rept. Asahi Glass Co., Ltd., Research Lab. No. 17*, 39–55(1927).—Durability and density of a glass increase with the progress of annealing. The surface of annealed glass is far more durable than its interior. A cleaned glass, consisting of SiO₂ 69.43, CaO 11.49, Na₂O 16.46, Fe₂O₃ and Al₂O₃ 1.46, MgO 0.66 and SO₃ 0.63%, was heated at 600° for 30 min. in a current of acidic gas or vapor. After cleaning, it was placed in moist air at 60° until it was permanently dimmed. The following figures give the time required for permanent dimness after treatment with the various reagents: untreated glass 1, air 3, steam 3, combustion gases from coal gas 4, SO₂ 10, H₂S 21, Cl 21, HCl 21, H₂SO₄ 21, CO₂ 22, Br 23, NO 25, HNO₃ 25, H₂SO₃ 35. The same glass was exposed to the action of various reagents at lower temps. and tested for its durability. The time in days required for permanent dimness after treatment with cold HNO₃ for 10 days was 2, cold fuming H₂SO₄ for 10 days 2, boiling N Na₂CO₃ soln. for 3 hrs. 2, steam at 100° for 1 hr. 6, concd. H₂SO₄ at 130° for 3 hrs. 7, boiling 1% H₃PO₄ for 3 hrs. 10, boiling water for 3 hrs. 13, boiling 5N HCl for 3 hrs. 14. To find the action of various reagents under pressure, the glass and each reagent were sealed in a test tube and heated at 120° for 3 hrs. The time in days required for permanent dimness was CO₂, dry 1, CO₂, moist 6, SO₂, dry 2, SO₂, moist 12, HCl, dry 4, HCl, moist 7, water 13. Five g. of the same glass ground to 0.5–1.0-mm. size was boiled in distd. water. The following figures give the no. of hrs. of boiling, loss in mg. at 100° and at 100 – 500° , no. of mg. of alkali dissolved calcd. as Na₂O: 1, 6.8, —, 2.7; 2, 10.9, 0.3, 4.0; 3, 13.3, 0.7, 5.1; 5, 13.8, 1.1, 5.0; 7, 16.2, 1.4, 6.1; 10, 19.3, 1.6, 6.7. The result indicates that water penetrates to the interior of the glass on long boiling.

S. KONDO

"Rational" analysis of clays. W. SINGLETON. *Chem. Age (London)* 18, 6–7, No. 451, *China Clay Trade Rev. Sect.*, No. 455, 7(1928).—The usual better-known procedures are not given but modifications to provide either greater accuracy or speed are reviewed. The most useful is Kallauner's method which consists of igniting the sample at 750 – 800° for about 2 hrs., and digesting with HCl to dissolve the Al₂O₃ of the clay present. This Al₂O₃ calcd. as kaolinite is subtracted from 100 to give the quartz and feldspar present. These may be detd. microscopically or by chem. analysis for the K₂O or the Al₂O₃ present in the residue of the HCl treatment.

H. F. K.

The varieties of clays of Washington and their adaptability to ceramic industry. EDW. BURKHALTER. *Bull. Am. Ceram. Soc.* 7, 236–9(1928).—Brief descriptions are given.

C. H. KERR

Kaolin content of clays. H. BOEGE. *Chem. Erde* 3, 341-69(1927).—Chem. analyses are given of eight clays from German localities. By digesting the material in HCl (d. 1.1) for 2 hrs. from 6.00 to 14.08% $\text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$ passed into soln., this represented the colloidal portion of the Al silicate. After ignition of the material at 700° HCl extd. more (up to 36.82%) Al_2O_3 , the addnl. amt. representing the broken-down kaolin. From these results the amt. of kaolin in the clay can be calcd. The amt. of HCl present in each of these clays was also detd. by the dehydration method of Calsow (C. A. 21, 3112). B. C. A.

Mineralogical constitution of clays. G. LINCK. *Chem. Erde* 3, 370-4(1927).—Remarks on the paper by Boege (preceding abstract). B. C. A.

Fuel mixing with clay. R. C. GANGWERE. *Bull. Am. Ceram. Soc.* 7, 234-6 (1928).—Mixing fuel or cinders with the clay in making heavy ceramic products may show great economy in firing cost. C. H. KERR

China clay preparations in England and Czechoslovakia. R. C. CALLISTER. *J. Council Sci. Ind. Research* 1, No. 4, 242-8.—C. describes the mining and treatment of certain crude clay deposits to extract the china clay. Several general processes are used: (1) After preliminary treatment the clays are purified by electroosmosis. This treatment also serves to replace filter pressing. (2) Method of sedimentation and filter pressing. (3) Cornish method. The clay is obtained by hydraulic methods which serve to remove coarse particles by deposition. The dil. clay suspension is gradually thickened and finally dried. L. B. MILLER

Effect of reducing gases on the transverse strength of fireclay bricks. A. E. R. WESTERMAN. *Ceramic Eng. Expt. Sta., Univ. of Illinois. J. Am. Ceram. Soc.* 11, 633-8(1928).—The effect of city gas, for 56 hrs., at 550° and at 1100°, upon 3 brands of brick, showed no significant change in transverse strength at 1100°; at 550° 2 of the brands showed small decreases in strength, while the 3rd brand, although highest in Fe content, was unaffected. C. H. KERR

Cause and prevention of kiln and dry-house scum and of efflorescence on face brick walls. L. A. PALMER. *Bur. Standards, Tech. Paper* No. 370, 579-629(1928).—The results of 288 panel tests continued over a period of six months indicate that limes, portland cement, brick layers' cement, etc., used either in the brick wall or as backing, contribute to the development of wall efflorescence. An admixture of either NH_4 or Ca stearate to mortar materials in an amount equal to 2% by wt. of the lime or cement will tend to prevent efflorescence. Sol. salts existing in the raw clay or formed during the mfg. process may also cause efflorescence. Dry-house scum or efflorescence is defined as the scum or efflorescence formed on the brick during drying. It is presumably due to the presence of sol. salts, especially Na_2SO_4 and K_2SO_4 , in the raw clay and once formed is very difficult to remove. It may be overcome by rapid drying, a reducing atm. in the kiln held at a temp. below the melting temp. of Na_2SO_4 , or by barium treatment. Sol. compds. of Ba such as BaCl_2 or $\text{Ba}(\text{OH})_2$ are preferable to BaCO_3 . BaF_2 is also used. Kiln scum may be due to sol. salts in the raw clay but is generally due to the reaction of SO_2 from sulfur in the fuel with basic constituents in the surface of the brick. Passing through the period of water smoking and through the temp. range 700 to 1000° F. as rapidly as possible decreases scum formation. Burning with a reducing atm. is also helpful. A brick contg. less than 0.05% of water-sol. SO_4 in the outer $\frac{1}{8}$ inch of its surface is fairly safe from efflorescence. LEWIS B. MILLER

Refractories: Their manufacture and applications. J. F. HYSLOP. *World Power* 10, 137-44, 256-78(1928).—Survey of the characteristics of the chief refractory materials, silica and silica-alumina, illustrating the main factors which det. their service behavior and use: strength, effect of temp., elec. properties, etc. C. G. F.

Refractories for brass foundry furnaces. H. M. ST. JOHN. *Metal Ind. (London)* 32, 543-6(1928).—See C. A. 22, 2647. E. G. R. ARDAGH

Properties of refractories, their testing and behavior in operation. F. KANHÄUSER AND J. FLÉK. *Chem. obzor* 3, 18-20, 44-6, 85-6, 103-10, 145-51(1928).—The properties of ten refractories, their micro- and macroscopical structure, behavior in heat and principal methods for testing are described. Detns. of refractoriness by a modified procedure of Endell, detn. of porosity by using Hartmann's volumeter, Endell's method of testing resistance to sudden temp. changes, and detn. of chem. resistance by using Hartmann's method are criticized. Photographs of app. and bibliography are added. JAR. KUČERA

The thermal expansion of refractory construction materials. (A synopsis of the literature.) K. SCHÖNERT. *Arch. Eisenhüttenw.* 1, 379-86(1927).—The heat expansion curves of refractories are influenced by: (I) the firing temp. and its duration; (II) the chem. compn.; (III) the sp. gr.; (IV) the porosity; (V) the grain size. From

the results found in the literature, the influence and mode of action of these factors are studied, the refractories investigated being silica brick (contg. quartz, cristobalite, tridymite), ordinary fireclay brick ($\text{Al}_2\text{O}_3:\text{SiO}_2$ ratio (VI) being approx. 1:2 and $\text{Al}_2\text{O}_3 = 38-46\%$), alumina-rich fireclay brick (VI > 1:2, $\text{Al}_2\text{O}_3 > 46\%$), silica-rich fireclay brick (VI < 1:2, $\text{Al}_2\text{O}_3 < 38\%$), magnesite, chromite and SiC bricks. The permanent and the temporary expansion of silica bricks depend on I, II, III and V, the effect of IV being still uncertain. Results of Miehr, Immke and Kratzert (*C. A.* 21, 3113) obtained

by the use of the relation: $\frac{\text{linear expansion}}{\text{sp. heat}}$ are unreliable, as the expansions were

not detd. on the same bricks as were the sp. heats. The relation appears to be const. for temps. up to 1400° , being about 5.4. The heat expansion of fire-bricks is detd. mainly by II, although I, V of the free SiO_2 therein and, to a lesser degree, IV are of significance. Here, the expression: $\frac{\text{linear expansion}}{\text{sp. heat}}$ is const. at a given temp.

but increases with the temp. (at 600° is 1.89, at 1000° is 2.73, at 1300° is 3.20). The expansion coeffs. as detd. by various investigators for magnesite are in good agreement, there being a slight increase in the coeff. with increase in firing-temp. Detailed expts. of the expansions of chromite bricks could not be found, the coeffs. given being, however, in good agreement. SiC has a const. value for the coeff. of expansion of 47.1×10^{-7} for the entire range from 0 to 1700° . With clay for a binding material, there is a slight increase in the coeff. of the material with increase in firing-temp. The influence of various binding materials has not yet been investigated. An extensive survey of the literature is given

J. BALOZIAN

Measurement of the electrical resistance of porous materials. A. E. KNOWLER. *Proc. Physical Soc.* 40, 37-40(1928).—The resistance of a specimen of refractory material is detd. by passing a known current through and measuring the potential between two wires inserted in it a known distance apart. The method avoids errors due to contact resistances.

Enamels containing antimony. F. M. LITERSCHIED. *Z. Untersuch. Lebensm.* 55, 296-7(1928); cf. *C. A.* 22, 2040.

WILLIAM J. HUSA

The effect of lepidolite in a high-tension electrical porcelain body. ROBT. TWELLS. General Elec. Co. *J. Am. Ceram. Soc.* 11, 644-8(1928).—Lepidolite was tried as a substitute for feldspar. Results show that changing the RO by molecularly replacing K_2O by Li_2O raises the vitrification temp., but replacing feldspar, lb. for lb., by lepidolite lowers the vitrification temp. Lepidolite gives a fine, white appearance. The chief improvement due to lepidolite is increase in resistance to thermal shock. Lepidolite is too expensive for wide use. Its chief ceramic use will doubtless be in glass and enamels where the full benefit of its F content and low fusing temp. can be utilized.

Apparatus for producing mold charges of molten glass. WILLIAM J. MILLER (to Hartford-Empire Co.). U. S. 1,681,127, Aug. 14.

Apparatus for making sheet glass. JOTHAM F. BLACK (to Hartford-Empire Co.). U. S. 1,680,588, Aug. 14.

Apparatus for forming sheet glass. HARRY G. SLINGLUFF (to Pittsburgh Plate Glass Co.). U. S. 1,679,504, Aug. 7.

Apparatus for producing and rolling sheets of glass. JAMES C. BLAIR (to Libbey-Owens Sheet Glass Co.). U. S. 1,680,241, Aug. 7.

Apparatus for drawing glass in endless sheets. LEWIS D. BLACKSHERE (to Libbey-Owens Sheet Glass Co.). U. S. 1,680,240, Aug. 7.

Forming sheet glass. LEOPOLD MAMBOURG (to Libbey-Owens Sheet Glass Co.). U. S. 1,680,227, Aug. 7. A protective film such as a graphite "para mica" and oil mixt. is applied by spraying to either the glass sheet or to parts of the app. with which the sheet comes into contact during its formation.

Sheet or plate glass. Y. BRANCART. Brit. 282,638, Dec. 21, 1926. Air or other suitable gas is introduced between sheet or plate glass and its support, to equalize cooling of the 2 sides of the material. An app. is described.

Uniting different layers of glass by rolling. Y. BRANCART. Brit. 282,637, Dec. 21, 1926. Mech. features.

Tunnel leer for annealing glassware. THOMAS E. BEACH (to Hartford-Empire Co.). U. S. 1,680,361, Aug. 14.

Glassware. PIERRE ARBEIT (to Hartford-Empire Co.). U. S. 1,680,357, Aug. 14. A flame is directed upon the region of the surface of glass in a tank where gathering takes place to reheat glass which may be chilled by contact with a gathering implement.

Blowing hollow glassware. HENRY W. INGLE (to Hartford-Empire Co.). U. S. 1,680,544, Aug. 14. Mech. features.

Molding bottles or similar hollow glassware in single-mold machines. KARL E. PEILER (to Hartford-Empire Co.). U. S. 1,680,746, Aug. 14. Mech. features.

Glass for incandescent lamps. COMPAGNIE DES LAMPES. Fr. 634,384, May 14, 1927. Flame-colored glass is made by adding red oxide of iron, MnO_2 , and niter to a standard compn. of clear glass.

Purification of kaolin. YVES M. PIRAUD. Fr. 633,745, May 3, 1927. The kaolin is made into a milk in water and colloids such as gum arabic, gum tragacanth, agar or pectin, etc., are added which transforms the kaolin into the colloidal state and the impurities settle.

Silica articles. EUGENE HERZOG (to General Electric Co.). U. S. 1,680,681, Aug. 14. Massive silica articles are heated at the time of their manuf. (or for repair) to "an ambient temp." of about 1000° and the surface of the article is locally fused while the article as a whole remains unfused; the article is annealed before cooling begins. An app. is described.

Ceramic material. F. SINGER. Brit. 282,403, Dec. 17, 1926. A ceramic material of low coeff. of expansion is formed by mixing steatite or other similar compd. of Mg or of the alk. earths, in the solid state, with Al compds. and heating until 3 phases are formed, one phase being a glass having a n of 1.53-1.55 and the other 2 phases being crystallites, the first crystals of the sillimanite type, including mullite, and the second

crystals of the forsterite and enstatite type. Brit. 282,404 relates to preventing aging of ceramic materials (minimizing the formation of amorphous constituents) by adding compds. of elements such as Ce, Zr, Cr, Mn, P, W and V to the main ingredients comprising silicates of Al or Mg and double compds. of these fundamental constituents such as kaolin, quartz and feldspar clay, steatite and $\text{Al}(\text{OH})_3$, kaolin and magnesite. The addns. may be in the form of oxides, carbonates, silicates or aluminates.

Drying chambers for ceramic materials. ALBERT GÉIS and LÉON FRITSCH. Fr. 634,101, May 10, 1927. The drying chambers are heated indirectly by the smoke from the furnaces.

Casting ceramic articles. ARTHUR O. AUSTIN (to The Ohio Brass Co.). U. S. 1,679,345, Aug. 7. A slip is deposited about a yielding core which may be formed of rubber and the core is removed from the formed article.

Centrifugal molding of insulators or other porcelain articles. LAURENCE R. WILDER. U. S. 1,680,832, Aug. 14. Mech. features.

Refractory materials. COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 634,021, May 7, 1927. A refractory material is made from a refractory metallic oxide, such as zirconia, with lime and short white asbestos fibers. An example gives 65% of zirconia, 5% of slaked lime and 30% of asbestos. The mixt. is moistened with water, molded and heated in a furnace and then submitted to steam pressure and again dried.

Refractory structure with vertical passages, for air heaters, etc. OTTO STRACK (one-half to the Firm Pfälzische Chamotte- und Thonwerke Schiffer & Kirscher A.-G.). U. S. 1,679,993, Aug. 7. Structural features.

Abrasive compositions. L. E. BARRINGER (to British Thomson-Houston Co., Ltd.). Brit. 281,711, Dec. 3, 1926. Grinding-wheels, whetstones, "sand paper" or other abrasive articles are made of abrasive grains bonded with a condensation product of a polybasic acid and polyhydric alc., suitably with the addn. of plasticizing agents such as indene polymer, tricresyl phosphate, glycol diacetate, diethyl phthalate, benzyl benzoate, triacetin, cumar resin, ester gum, pitch, diphenyl or a natural gum. The material may be molded hot and subsequently cured under heat and pressure.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Volume changes in portland cement as affected by chemical composition and aging. ALFRED H. WHITE. Univ. of Michigan. *Proc. Am. Soc. Testing Materials* 1928 (preprint 56), 24 pp.—Aging of sound portland cement prior to use does not minimize vol. changes in the hydrated cement caused by continuous storage under water or by changes in its moisture condition. A cement burned from a normal raw mix to which 5% of 12-20 mesh calcite had been added, and therefore contg. free lime, showed excessive increase in vol. after hardening when stored in water and in air. After exposing the same clinker outdoors for 4 months the cement exhibited normal vol. changes. One and two % of finely ground, hard-burned magnesia added to cement did not greatly affect vol. changes observed over a period of 26 years. The same cement with 3% added MgO was about normal for 3 years, showed a marked expansion for the next 5 years and was normal thereafter, the total expansion being about 1.1%. Similar behavior was observed with cements from lab.-burned clinker which from its compn. presumably contained free MgO . Portland cements high in Al_2O_3 had rather rapid but otherwise normal expansion. A high Fe_2O_3 content in portland cement apparently decreases vol. changes. RAYMOND WILSON

Volume changes in hydrated portland cement. ALFRED H. WHITE. Univ. of Michigan. *Cement* 33, No. 2, 41-5 (1928).—The stiff gel which is one of the products of hydration of portland cement absorbs and gives up water with changing humidity. The length of a neat cement bar may vary by as much as 0.5% between the dry and the satd. state (cf. C. A. 13, 2117). RAYMOND WILSON

Alternate hardening of portland cements. HANS KIEHL. *Pit and Quarry* 16, No. 9, 43-6 (1928).—Data are given on mortar strengths in tension and compression of 25 cements cured in water, in air and by various combinations of the 2 methods. RAYMOND WILSON

The effect of litharge on the hardening of portland cement. BERNWARD GÄRNER. *Z. anorg. allgem. Chem.* 169, 305-8 (1928); cf. C. A. 22, 149. RAYMOND WILSON

The effect of several mechanical features of testing on the determination of the

flexural strength of plain concrete. T. F. WILLIS AND F. N. WRAY. Missouri State Highway Commission. *Proc. Am. Soc. Testing Materials* 1928 (preprint 64), 9 pp.—The relation between the results obtained by several different methods and the effect of certain features, such as length of span, type of bearings, and rate of application of stress, are shown. Results obtained with the different methods vary widely, indicating the need for standardization of this test. RAYMOND WILSON

Some accelerated freezing and thawing tests on concrete. C. H. SCHOLER. Kansas State Agr. Coll. *Proc. Am. Soc. Testing Materials* 1928 (preprint 62), 15 pp.—The alternate freezing of satd. concrete at low temps. and thawing at room temps. is a valuable means of studying the durability of concrete and concrete aggregates. Variations in the water-cement ratio of plastic workable concrete have a very marked effect upon its durability. A water-cement ratio of 1.0 is near the max. permissible for a desirable durability of concrete in exposed situations. The use of unsound aggregate produces unsound concrete, the resistance of the mortar to disintegration being only slightly effective in protecting the aggregate. The disintegration of concrete through the failure of the mortar is a surface action and the outside is very badly disintegrated before the interior is affected. The phys. characteristics of the mortar after failure are such as to give the impression of chem. or soln. action. The results secured are comparative only, and it is not feasible to translate them into actual length of life under natural conditions. RAYMOND WILSON

Concrete control methods in the construction of a filtered-water reservoir. W. C. MABEE. *J. Am. Water Works Assoc.* 19, 193-200(1928).—The ratio of water to cement when mixing concrete was made part of the contract when constructing a covered, filtered-water reservoir for the Indianapolis Water Company. A 28-day strength of not less than 2500 lb. per sq. in. in compression was aimed at and achieved by careful control of this ratio and by study of the conditions relative to aggregates, time of mixing, distribution, placing, puddling, etc. On test, under 14-ft. head, the tank lost only 0.3% of its volume in 24 hrs. B. C. A.

Failure of lean concretes to harden. BERNWARD GARRE. *Z. anorg. allgem. Chem.* 169, 301-4(1928).—Quantities of salts in aggregate or mixing water which would not noticeably affect rich concrete may prevent hardening in lean concrete. R. W.

Experimental tests of concrete-steel bond. L. N. EDWARDS AND H. L. GREENLEAF. Maine State Highway Commission. *Proc. Am. Soc. Testing Materials* 1928 (preprint 65), 14 pp.—Bond tests were made on specimens molded with 1-in. rods placed horizontally. Mineralogical and granulometric compn. affect bond strength. High cement content may reduce bond strength, probably because of greater vol. changes on drying. Very wet mixts. have lower bond strength than plastic mixts.; the lower surface of the bar as molded has little or no bond with very wet mixts. R. W.

Tests of clay and concrete load-bearing pipe. W. J. SCHLICK. Eng. Expt. Sta. Iowa State College. *Proc. Am. Soc. Testing Materials* 1928 (preprint 66), 12 pp.—This paper discusses some of the more common problems of test procedure. Particular attention is given the problems encountered in the use of the two most common of the standard bearings, sand bearings and three-edge bearings, in tests of different sizes and classes of pipe and to the necessity for controlling the moisture and temperature of the specimens if truly comparable test results are to be obtained. The real meaning and value of the absorption test are discussed and certain common, but incorrect, procedures in the drying and immersion treatments are pointed out. The freezing and thawing test is the only direct durability test that has been standardized. The problems of durability against chem. attack have been solved only partially. R. W.

Deterioration of structures of timber, metal and concrete exposed to the action of sea-water. JOHN PURSER AND H. J. GROSE. *Dept. Sci. Ind. Research, 8th Rept. Comm. Inst. Civil Engineers* 1928, 75 pp.—This report is a brief summary and abstract of a broad field study of deterioration of exptl. structures carried on by the committee over a period of years. Included are a summary of reports on periodical exams. of the iron and steel specimens exposed at Colombo, Plymouth, Halifax and Auckland, a report on the final examn. of the first series of iron and steel specimens exposed at Auckland, N. Z. over a period of 5 years, a summary of report on the periodical inspection of the first series of painted steel plates exposed to aerial corrosion at Southampton, a report on the painting of a second series of steel plates for exposure to sea action, a report on work on the protection of timber, a report on the condition of specimens of timber exposed to sea action and a report on expts. on reinforced-concrete test blocks, with various depths of cover, exposed at Brisbane. There is, in general, but little difference between the rates of corrosion of Low Moor wrought iron and mild steel when exposed to complete immersion in the sea. In the alternate wet and dry

tests the advantage lies with the wrought iron, but in the aerial tests the mild steel proved distinctly superior. The presence of S in steel tends to enhance its rate of corrosion. The addition of Cu up to about 2% enhances to an appreciable extent the resistance of the metal to corrosion. Cr and Ni steels are very resistant to sea air and to alternate exposure to sea water and air. Under conditions of continuous immersion in sea water, the advantage over wrought iron and C steels is less marked insofar as loss in wt. is concerned. They are, moreover, liable to very severe pitting. The cast irons apparently proved the most resistant metals to corrosion when loss in wt. and pitting are considered. In certain cases there is evidence of internal corrosion and this is being investigated. When dissimilar metals are placed in contact or riveted together, there is a tendency for one metal to be preserved at the expense of the second, which corrodes very severely. This is especially noteworthy where mild steel is in contact with Cr or Ni steels, the mild steel undergoing rapid disintegration, while the alloy steels remain practically perfect. In general, bars that had been ground free from scale before exposure lost less in wt. and appeared less deeply corroded than when exposed with the scale adhering. Attention is directed to the extreme danger of drawing conclusions from isolated and unconfirmed tests. In this connection it is indicated how marine growths may mislead the investigator. At one place oil present on the surface of the sea afforded some protection to the corroding metals. One steel, high in S and P and low in Mn, was the worst steel bar as regards pitting and loss in wt. in the aerial tests. Impregnation of wood was found to be much better than painting as a protective measure. Tar was found to be very effective as a preservative of steel plates exposed to corrosion. Biol. studies on various marine organisms causing deterioration of wood structures are being continued.

L. B. MILLER

Report of Committee D-4 on road and paving materials. JULIUS ADLER, *et al.* *Proc. Am. Soc. Testing Materials* 1928 (preprint 73), 34 pp.—A tentative method of test for abrasion of gravel, a tentative recommended practice for bituminous paving plant inspection and several minor revisions of existing tentative standards are proposed. An appendix gives results of distn. tests by several labs. on 2 tars using Engler and E-1 distn. flasks. Agreement between the 2 methods of test is of the order of 2%. R. W.

Slag bricks and paving stones in Germany. A. GUTTMANN. *Arch. Eisenhüttenw.* 1, 339-44(1927).—Processes in use in Germany for the manuf. of slag building bricks are indicated, and the suitability of blast furnace slags for such purposes is discussed. The properties of the bricks are described and methods for testing their strength suggested.

J. BALOZIAN

Experiments with blast-furnace slag pieces as track bedding material. H. BURCHARTZ AND C. SAENGER. *Arch. Eisenhüttenw.* 1, 177-86(1927).—Comparative tests are made with 9 slags and 9 quarry stones, including their resistance to the action of rain and frost, their chem. action on Fe and wooden sleepers and the resistance of the materials to breaking (according to Rudeloff). From these expts. it is apparent that the slags tested are equiv. to most scrap quarry stones.

J. BALOZIAN

The rational carbonization of wood. V. GAMBAROTTA. *Notiz. chim.-ind.* 3, 355, 357(1928).—Various reasons are given to show that the present practice of carbonizing wood in heaps to charcoal is so uneconomical that it should be replaced by new and better systems, where the wood is heated in the absence of air and the by-products are recovered completely. The distn. equipment should be located at the source of the wood. Some of the present types of portable app. are superior in various respects to carbonization in heaps, particularly in the much higher yields, and carbonization by the older method should immediately be discontinued in favor of portable app. carbonizing where the wood is obtained.

C. C. DAVIS

Prevention of sap stain in white pine. C. E. DIXON. State Forest Service, Wellington. *New Zealand J. Agr.* 36, 118-24, 194-200(1928).—Sap stain of New Zealand white pine (*Podocarpus dactyloides*) is caused by (1) chem. action due to enzymes in the wood which produce more or less permanent discoloration in both the heartwood and sapwood and (2) fungal attack which produces blue discoloration resulting from several genera of fungi, mostly *Penicillium* and *Cladosporium*, which feed on the sol. sugars present in the sapwood. Sap stain attack may be retarded and almost eliminated by (a) dipping the freshly sawed timber in a satd. borax soln. and (b) by using the open-filletted box type of stacking. Neither (a) nor (b) is in itself sufficient to prevent sap stain attack, and both operations must be carried out in conjunction.

K. D. JACOB

Concrete-lined [oil] storage reservoir (HOUGH) 22. The essential oil of "Hiba"-wood and its relation to the resistance of the wood to destruction by fungi (UCHIDA) 17.

Examination of a Nigerian lignite [for cement manufacture] (WOOD, NICHOLAS) 21. Furnaces [for cement and gypsum] (Fr. pat. 634,013) 1. Phosphoric acid and calcium compounds [cement aggregate] (Fr. pat. 633,828) 18. Rubber-composition flooring (U. S. pat. 1,678,948) 30. Distilling oil shale [product for use in cement manufacture] (U. S. pat. 1,678,751) 22. Fungicides [for wood treatment] (Fr. pat. 634,605) 15. Spraying apparatus for coating stone (Brit. pat. 281,885) 1.

SPARRE, DE: Determination du coefficient d'élasticité du ciment ou du beton au moyen de la vitesse du coup de bélier dans les conduites. Paris: Gauthier-Villars et Cie. 6 pp. F. 1.

Cement. DR. A. WACKER GES. FÜR ELEKTROCHEMISCHE INDUSTRIE. Brit. 282,458, Dec. 20, 1926. Dry $\text{Ca}(\text{OH})_2$ obtained from producing C_2H_2 by reaction of a small proportion of water on CaC_2 is mixed with clay or other siliceous and aluminiferous material to form portland cement.

Cement. G. POLYSIUS. Fr. 634,518, May 17, 1927. A fused aluminous cement is made by charging the crude substances in lumps into a rotating furnace. Cf. C. A. 22, 3277.

Acid-proof cement. I. G. FARBERNIND. A.-G. Brit. 281,680, Dec. 1, 1926. Instead of pure Si, as described in Brit. 258,616 (C. A. 21, 3114), a pulverized alloy of Si with Mg, Ca, Al or Fe is added to waterglass cements. Cf. C. A. 22, 1225.

Apparatus and mixing system for hydrating cement or for similar operations. ERLE P. HALLIBURTON. U. S. 1,680,678, Aug. 14.

Pitch concrete for roadways, etc. MARCEL LEVY (to "Prodor" fabrique de produits organiques S. A.). U. S. 1,681,353, Aug. 21. A graded aggregate and filling material are incorporated into a hard pitch by the action of heat and this pitch concrete is laid as a substratum; it is hard and non-plastic and has a crushing strength of at least about 4000-5000 lbs. per sq. in. and a tensile strength, when the large aggregate is not present, of about 400-500 lbs. per sq. in. A thin adherent surface layer of plastic material such as asphalt is placed on this substratum.

Centrifugal molding of concrete pipes, etc. R. A. WHITSON. Brit. 281,941, May 17, 1927. Springy sheet metal liners are placed within the mold used and these may be coated with oil, wax and grease and may be withdrawn from the mold before its sepn. from the molded article. Various mech. features are described.

Artificial stone or plaster. W. A. OAKLEY. Brit. 281,757, Sept. 6, 1926. A hot soln. of MgCl_2 , FeCl_3 or other suitable chloride is added to a mixt. of MgO and a filler such as a carbonate, siliceous or aluminous clay, calcareous earth, kaolin, sand or CaSO_4 . A sulfate such as alum also may be added when a calcareous earth or alk. clay is used as a filler to produce a dry material which sets on addn. of water by mixing the ingredients in appropriate order. A small proportion of alk. silicate may be added to the chloride soln. when other fillers are used.

Tar for roads, etc. PAUL GLOESS and MICHEL MARINI. Fr. 633,687, Sept. 6, 1926. Alginic acid or alginates are used for making emulsions of tar, asphalt, oils, etc., to be used on roads.

Wall coverings on brick walls. R. J. BIEBER & Co. GES. Brit. 282,329, Dec. 14, 1926. Brick walls are coated with a waterproof cement (which prevents saline excrecence) and a covering material is directly applied to the moist cement without glue or paste.

Protective coatings on metal, wood, masonry or other surfaces. JOHN B. W. GARDINER. U. S. 1,678,980, July 31. An emulsion of bituminous material which may contain soap or clay and which is formed free from soap is applied to the surface and while still wet is covered with a layer of dry cement which abstracts water for its hydration from the emulsion.

Staining wood. GEORGE A. RICHTER, WALLACE B. VAN ARSDEL and JOHN G. GOSSELINK (to Brown Co.). U. S. 1,680,529, Aug. 14. Wood is heated above 100° to vaporize free moisture and expel the air content of the wood together with the steam produced; the wood is confined and is treated with NH_3 while hot, under pressure, and the stained wood is removed from confinement while still in heated condition.

Impregnating wood. WACŁAW IWANOWSKI and JOSEF TURSKI. Fr. 634,106, May 10, 1927. Di-, tri- or polychlorophenols or nitrochlorophenols or the condensation products of chlorophenols with AsCl_3 are used for preserving wood.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

The production of domestic fuel. IV. JOHN ROBERTS. *Gas J.* **183**, 153-4 (1928); cf. *C. A.* **22**, 3278.—Discussion of the Hellar-Bamag process. V. *Ibid* 211-2.—Systems employing producer-type retorts are described. The Sutcliffe briquetting and Midland Coal Products processes are discussed. VI. *Ibid* 265.—The MacLaurin and L. & N. processes are discussed. F. S. GRANGER

Testing and sampling of different fuels. *Izvestiya Teploekkh. Inst.* (Russian) (*Bull. Inst. for Fuel Research*) **1927**, No. 8, 65-93.—Instructions have been adopted by the "Second All-Union Fuel Congress" and "Fourth All-Union Mendeleyeff Chemical Congress" for the sampling and analysis of firewood, peat, lignite, coal and other fuels. These are contained in this article. A. A. BOEHTLINGK

National fuels (of Italy). L. VERTÙ. *Notiz. chim.-ind.* **3**, 421-2 (1928).—A discussion of the present fuel situation in Italy, with quant. data on the phys. and chem. characteristics of the most important Italian fuels. C. C. DAVIS

The use of carbon as an economic fuel (in internal-combustion engines). A. CHARLES ROUX. *Chimie et industrie* **19**, 793-800 (1928).—An address discussing the relative merits and disadvantages of various forms of C (raw wood, wood charcoal, peat charcoal, lignite charcoal, raw bituminous coal and semi-coke) for use in gas producers for automobiles. R. considers that by a suitable blending of these various materials a product (which he calls "granol") may be obtained suitable for use in automobiles, at a retail cost not over 50% that of gasoline (for the same calorific power) and in a form which could be distributed as conveniently and easily as gasoline. A. PAPINEAU-COUTURE

Low-temperature carbonization. DAVID BROWNLEE. *Iron Coal Trades Rev.* **66**, 940-1 (1928).—Twelve of the latest and lesser known low-temperature carbonization processes are described. LESLIE B. BRAGG

Low-temperature carbonization. C. H. LANDER. *Iron Coal Trades Rev.*, Diamond Jubilee Issue, 83-7 (Dec., 1927).—A review and discussion. LESLIE B. BRAGG

The "Turner" process of low-temperature carbonization. A. W. SANDERS. *Iron Coal Trades Rev.* **64**, 520-2 (1927).—The process, which consists chiefly of a continuous vertical retort, internally heated by superheated, low-pressure steam, is described in detail. Pressure is alternately built up and then suddenly released in the retort, which, it is claimed, assists in releasing the volatiles. LESLIE B. BRAGG

Some facts regarding the low-temperature carbonization of coal. G. S. HASLAM AND R. V. WHEELER. *Fuel in Science & Practice* **7**, 292-9 (1928); *Trans. Inst. Mining Eng.* **75**, Pt. 2, 175-87 (1928).—A discussion of the products obtained and technical and economic considerations of low-temp. carbonization. D. A. REYNOLDS

A general review of low-temperature carbonization. F. S. SINNATT. Sheffield, Eng. *Fuel in Science & Practice* **7**, 305-29, 364-75 (1928), cf. *C. A.* **22**, 1456.—Yields and compns. of tars and gases for the following processes are given: Parker, Midland Coal Prod., Fusion Rotary, Freeman Multiple, MacLaurin, Lehigh Smokeless Fuel, Illingworth, K. S. G., Salerno, Fuel Research. These and other processes are discussed. D. A. REYNOLDS

The relation between low- and high-temperature carbonization of coal. AKIRA SHIMOMURA. Kyoto Imperial University, Japan. *Fuel in Science and Practice* **7**, 119-27 (1928).—The behavior of 7 coals of different geological age during a 2-stage carbonization process is described. For the low-temp. carbonization test 20 g. of air-dried coal, passing a 0.25-mm. mesh, were heated to 500° in 45 min. in a Fischer Al retort, and that temp. was maintained for 45 min. For the high-temp. carbonization test 15 g. of semi-coke, passing a 0.25 mesh, were heated in a tube furnace from 500° to 900° in 40 min. and held at that temp. for 30 minutes. The yields of various products were detd. and the gas and coke analyzed. In these tests: (1) tar is driven off completely below 500°; (2) only 10 to 20% of the total NH₃ is formed below 500°; (3) the vol. of gas generated at the higher temp. is 2 to 2.5 times that generated at the lower temp. The differences in the values of low- and high-temp. gases are stated thus: (a) the yields of CO₂ and CO are reversed, the latter predominating in high-temp. gas; (b) practically no generation of unsatd. hydrocarbon gases occurs by further heating the semi-coke; (c) in the low-temp. gas, CH₄ and C₂H₄ exist in large quantities (30-35% and 13-22%, resp.), while H is low (9-21%). The high-temp. gas contains 55 to 70% H and 19 to 22% CH₄. D. A. REYNOLDS

Conversion of coal into oil by treatment with hydrogen under high pressure. J.

IVON GRAHAM. *Iron Coal Trades Rev.*, Diamond Jubilee Issue, 87-90(Dec., 1927); cf. C. A. 22, 1665.—A review and discussion. LESLIE B. BRAGG

The optimum utilization of coal. OTTO HUPPERT. *Z. Ver. deut. Ing.* 72, 975-83 (1928).—Developments in coal utilization by the use of the Haber-Bosch NH_3 synthesis process, newer gas producers employing powdered coal, manuf. of $(\text{NH}_4)_2\text{SO}_4$ from NH_4OH and gypsum, prepn. of NaNO_3 and HNO_3 , coal-gas distn., by-product coke ovens, low-temp. distn. processes, prepn. of petroleum substitutes, hydrogenation of coal and tar, reactions involving CO , CO_2 and H to produce alcs., aldehydes and acids, gas producers with O-feed, Bergius process for oil production, hydrogenation of hydrocarbons, use of selective catalysts to produce specific substances, the controlled oxidation of CH_4 to form CO and H_2O or CO_2 and H , are discussed in a most general way. Recent work of the I. G. Farbenindustrie is given prominence. W. C. EBAUGH

Developments in coal treatment and utilization. JOHN CADMAN. *Iron Coal Trades Rev.*, Diamond Jubilee Issue, 70-2(Dec., 1927).—A review and discussion. LESLIE B. BRAGG

The treatment and utilization of coal in gasworks. G. M. GILL. *Iron Coal Trades Rev.*, Diamond Jubilee Issue, 78-83(Dec., 1927).—A review. L. B. B.

The present stage of British coal cleaning. HENRY LOUIS. *Iron Coal Trades Rev.*, Diamond Jubilee Issue, 67-70(Dec., 1927).—A review. LESLIE B. BRAGG

Spontaneous heating of coal. JOSEPH D. DAVIS and D. A. REYNOLDS. *Bur. Mines, Tech. Paper* 409, 74 pp.(1928).—The affinity of coal for O and other properties and conditions which underlie its tendency to heat spontaneously, the erratic heating behavior of coal in storage, and some common storage practices are discussed. The important results obtained in different countries during the past 50 yrs. through fundamental investigations on the factors which influence spontaneous heating of coal are assembled and correlated with the work done on this subject by the Bureau of Mines, discussions being limited mainly to work done since 1900. The names and chief contributions of each of the prominent investigators are given in approx. chronological order, followed by a general summary of conclusions to be drawn from their researches. The theories of spontaneous heating of coal, early pyrite, coal-O complex, reactions of parts of coal with O and equil. between coal and O are explained. The methods which have been used to det. the oxidizing tendency of coals are divided into large-scale tests and lab. methods; of the latter there are 4 general classes: those that depend on the self-heating of coal at elevated temps., isothermal, adiabatic and purely chem. methods. An extended critical review of these methods, with their variations and of results obtained by each, is given together with abstracts of the data secured, 14 sets of graphs, some drawings and descriptions of app. used, and 3 photomicrographs showing banded constituents and fine pyrites in coal. These reviews include oxidation expts. on samples of whole coal, wet, dry and preheated to various temps.; on each of the banded constituents of coal including mineral charcoal; on materials extd. from coal by solvents; on coals treated with CaCl_2 , $\text{Ca}(\text{OH})_2$, NaHCO_3 , FeSO_4 , NaOH , KOH , NH_4OH , ozone, and bacteria; of weathering and ulmification; and on low-temp. cokes. Expts. on the chem. and phys. factors affecting spontaneous heating of coal are also considered. The authors present these conclusions: All coals except anthracites undergo spontaneous heating; the chem. constitution of coal varies with its rank and low-rank coals heat more easily than high-rank or older coals; oxidation of the coal substance itself is the main cause of spontaneous combustion, but no one constituent exerts a preponderant influence. The 1st stage in spontaneous heating is operative at room temp. as soon as freshly broken coal is exposed to the air and consists in the formation of a solid compd. of coal and O; the 2nd stage involves the decompn. of this compd. and with Appalachian coals begins at about 85°F and is completed at about 445°F . There is no sharp transition temp. from one stage to the other and both processes go on simultaneously from about 85° to 445°F . Pyrite present in finely divided form is a contributing chem. factor, but is seldom the detg. one. Moisture other than being needed for the oxidation of pyrite is probably not a chem. factor. Org. S, ozone in the air, other chemicals tested and bacteria are not important practical factors. The most important phys. factors are size of coal and the initial temp. of exposure, provided sufficient O is present to sat. the coal. Heat capacity and cond. depend largely on moisture content and size of coal. Occluded gases probably have little effect. Suggestions made applying these conclusions to storage of coal are to exercise special care in storage of sub-bituminous coals and non-storage of coals contg. fine pyrites; avoid segregation of fine coal in the storage pile and carefully exclude foreign matter; wetting down the surface of the whole pile changes its ventilation and may favor heating at points not reached by the water. It is well to use temp. measurements to a depth

of at least 6 ft. from the surface of the coal pile. In common practice 150° F. is considered as approaching the danger point, but the heating curve for coal is a smooth one with no sharp breaks. The most fruitful studies of the future will probably be those that deal with storage conditions, especially on the effect of air supply. A nine-page bibliography containing over 200 references is included in this tech. paper.

W. W. HODGE

Combustion of powdered coal. B. MOORE. *Trans. Inst. Chem. Eng.* (advance proof), March, 1928, 12-24.—The degree of fineness of powdered coal affects considerably its rate of combustion, ignition properties, and "combustible capacity," as detd. by the method previously described (*C. A.* 19, 2398; 20, 3553). The rate of combustion increases and the "glow point temp." falls with increasing degree of fineness of the coal. The results indicate that there is a critical temp. and a critical degree of fineness at which the combustion of the particles becomes almost instantaneous.

B. C. A.

Wetting and its measurement. E. F. GRIEG. Sheffield, Eng. *Fuel in Science & Practice* 7, 136-8(1928).—G. measures the resistance to the spread of a liquid through coal dust by use of a modified form of the Sven Oden continuous weighing balance. The method is described and illustrated.

Notes on recent developments in fuel technology. R. WIGGINTON. *Fuel in Science & Practice* 7, 287-9, 333-5(1928); cf. *C. A.* 22, 2254.—Brief reviews of the following subjects: rockets, sea-temperature energy, vanillic acid from lignin, flue dust recovery, a high-pressure locomotive.

D. A. REYNOLDS

Kizel coals in U. S. S. R. N. P. CHIZHEVSKII. *J. Chem. Ind.* (Moscow) 5, 11-3 (1928).—The compn. of Kizel coals is as follows: ash 17.43-28.62%, S 5.2-7.86%, moisture 0.77-0.79%, volatile matter 37.25-38.66%, coke 60.56-61.96%. Microscopic examn. shows that S presents itself chiefly in the form of pyrite grains of less than 0.5 mm. size. Preliminary expts. have established that the coals may be enriched considerably by means of flotation after being pulverized. The cokes obtained from these coals by distn. on a small scale are hard and generally of good quality. Distn. of the coals on a large scale is being considered.

BERNARD NELSON

The "Kohlenveredelungs" process. DAVID BROWNLIE. *Gas Age-Record* 62, 129-31, 138(1928).—The "Kohlenveredelungs" retort for the continuous low-temp. carbonization of semi-dried lignite, a modification of the "Rolle" retort, is described. A plant, including 8 retorts and having a capacity of 480 tons of semi-dried lignite, 15-18% moisture, per 24 hours, is being constructed at Cothen-Anhalt, Germany.

LESLIE B. BRAGG

Some experiences gained in the control of the operation of steam boiler plants. GUSTAF EDLING. *Svensk Pappers-Tid.* 31, 277-9(1928).—An account is given of some experiences gained by the "Mellersta och Norra Sveriges Ångpanneforening" (Central and North Swedish Steam Boiler Assocn.) in carrying out a caloritechnical control of the operation of steam-boiler plants. Attention is called particularly to the defects and unsatisfactory conditions frequently demonstrated by this control. Coal users should consider not only fuel guarantees, but the conditions under which the coal is to be used. Pre-heated combustion air is beneficial with wood fuels of high moisture content. Mech. stoking is recommended, but requires care and watching. Firing with wood-waste alone or with wood-waste on top of coal is advantageous. Use of cam-flange economizers utilizes heat of exhaust gases.

Dutch bog ore and gas purification. ANON. *Gas World* 89, 33(1928).—Dutch bog ore has displaced lime as the favored purifying agent. Its value cannot be based on the content of hydrated ferric oxide alone. A mixt. of H_2S and coal gas was passed over 3 specimens in which the % Fe_2O_3 decreased while the % org. fibrous matter increased. The one contg. the least Fe_2O_3 yielded the highest S absorption and *vice versa*, in consequence of the better penetration afforded by the presence of the fibrous matter. A 4th specimen, of about the same Fe_2O_3 content as the lowest of the other 3, but with the remainder consisting mostly of siliceous clay instead of fibrous matter, absorbed more S than the one of highest Fe_2O_3 content but less than the others. F. S. GRANGER

The synthesis of ammonia from coke-oven gas. THOMAS BIDDULPH-SMITH. *Iron Coal Trades Rev.* 66, 179-80, 222-3(1928).—The extn. of hydrogen from coke-oven gas, by the liquefaction of the other constituent gases, for use in the synthesis of ammonia is discussed. LESLIE B. BRAGG

Correlation of physical and chemical properties of cokes with their value in metallurgical processes. W. T. K. BRAUNHOLTZ, G. M. NAVE AND H. V. A. BRISCOE. Armstrong College, Newcastle, England. *Fuel in Science & Practice* 7, 100-17(1928).

—In an effort to correlate various properties of cokes with their known blast-furnace values chem. and phys. tests of the cokes were made. Shatter tests of 11 cokes were made by the U. S. Bureau of Mines method, modified slightly; in general, the blast-furnace values of these cokes increase with increasing shatter index and the quantity of fines ($< 1/8$ in.) caused by dropping increased with decreasing shatter index. Reliable results are obtained on using 25 lbs. instead of the usual 50-lb. samples. On using 50-lb. samples in a box 28 in. \times 18 in., there was indication of a cushioning effect not found with a box 30 in. \times 30 in. The cokes examd. varied little in density. Combustibility tests of 5 to 10 mesh (I. M. M.) coke in a const. air current were made in a silica tube-furnace of 2 in. internal diam. External heating was stopped at the time of ignition of the coke and fuel consumption was calcd. from the ratio of CO_2 to CO . Ignition temps. found were: by-product cokes 500° to 560° , beehive coke 613° , carbon 415° and activated charcoal 252° . The av. temp. maintained by the by-product cokes was 1180° to 1290° , by the beehive coke 1310° . These av. temps. showed no relation to the shatter indices; however, on dividing the cokes into 2 groups according to their max. temps., there was found a tendency for increasing fuel consumption to be accompanied by decreasing shatter index and decreasing "apparent" porosity. Methods for the detn. of sp. gr., porosity and water absorbed are given. By coking 50-lb. samples of coal contained in an iron box in full scale oven charges, it was found possible to obtain quant. information concerning the strength of the coke obtained from a given coal under given conditions. Further investigation of these "box" tests are to be made.

D. A. REYNOLDS

Determination of the coking value of coal. G. DORFLINGER. *Archiv. Eisenhüttenwesen* 1, 3-8(1927); *Rev. metal.* 25(Extraits), 263-6(1928).—In order to get coke of uniform quality, not only must the operating conditions be uniform, but so also must be the quality of the coal. The Borsig coking plant has devised a test (technic described in detail) for detg. the coking value of coal consisting essentially in sepg. the crushed coal into fractions of different d by means of $\text{CCl}_4\text{-C}_6\text{H}_6$ mixts. of d. 1.28, 1.32, 1.36, 1.40 and 1.595 and coking the various fractions in the lab. via Mück. Irregularities in the coking qualities of the coal can be compensated by judicious blending of the coal from different seams according to the results of the tests. A. P.-C.

Volatile matter and the reactivity of coke. YOSHIKIYO OSHIMA. *Imp. Fuel Res. Inst. J. Soc. Chem. Ind. Japan* 31, 506-7(1928).—O. has detd. moisture and volatile matter of coke under different conditions: (1) air-dried sample, (2) No. 1 sample but exposed to the atm. for 24 hrs. after the detn. of moisture and volatile matter, (3) No. 1 sample but exposed to the atm. for 24 hrs. after prepn. and (4) No. 1 sample but immersed in H_2O for 24 hrs. and then air-dried. From the result it is concluded that coke absorbs moisture which is not completely driven off at $105-10^\circ$, but remains at a higher temp. and it may be taken as a volatile matter. Volatile matter of coke is, therefore, not the same as that of coal, but mostly moisture absorbed or occluded and a part of it is eliminated at about 110° , while some of it can only be driven off at a higher temp. This is naturally due to the surface structure and it is accordingly correct to say that the reactivity is influenced by surface conditions, porosity and the state of C which govern the adsorption, but not the content of the so-called volatile matter.

K. KASHIMA

The effect of varying ash in the coke on blast-furnace working. C. S. GILL. *Iron Coal Trades Rev.* 65, 528-9(1927); cf. *C. A.* 21, 3868.—A 1% reduction in ash was found to save 42 lb. of coke per ton of pig and to give a 6.4% increase in make, with a more regular production.

LESLIE B. BRAGG

A process for partially dehydrogenating certain hydrocarbons in order to render them able to agglomerate carbon. ANDRÉ LÉAUTÉ and GEORGES DUPONT. *Compt. rend.* 186, 1558-60(1928).—Pitch, fuel-oil or coal-tar oil is heated with about 10% of S, when H_2S is liberated and partial dehydrogenation takes place. The product contains about 1% residual S, is more viscous and has much greater adhesive power than the original oil. It is suitable for use as a binder for briquetting fine particles of coal or C.

Vertical gas retort construction. R. B. PARKER. Brit. 282,418, Dec. 14, 1926. A sliding closure is arranged to vary the position of gas outlets at the upper portion of a retort to prevent channelling in the charge. Some other structural details are also specified.

Grate construction for retorts. R. B. PARKER. Brit. 282,419, Dec. 14, 1926.

Coal. ARVED PISTORIUS and CURT BUNGE. Fr. 634,351, May 13, 1927. See Brit. 277,293 (C. A. 22, 2456).

Pulverization of coal. ISAAC E. BRITT. Fr. 634,405, Sep. 14, 1926. The coal is carried along by a rapid current of compressed air and forced against baffle plates, which soon reduce it to powder.

Drying coal and other fuels. HANS FLEISSNER. U. S. 1,679,078, July 31. Coal or similar fuel of colloidal character is dried without disintegration by first heating it in satd. steam under pressure to a temp. (suitably about 120 – 180°) above that required for drying and then reducing the partial pressure of the steam to effect quick drying. Cf. C. A. 21, 2552.

Stable suspension and paste of coal. ROBERT GRIESSBACH and JULIUS EISELE (to I. G. Farbenind. A.-G.). U. S. 1,681,335, Aug. 21. In forming fuels, coal is mech. dispersed in a liquid alc. such as crude isobutyl alc. with addn. of a base such as NaOH, pyridine or aniline which is sol. in the alc.

Treating coal and oil for the production of liquid hydrocarbons. ALBERT E. HODGSON. Fr. 633,954, May 5, 1927. Finely divided coal is dispersed in an oil such as residual mineral oil, and the dispersion is heated under pressure if necessary. A part of the coal unites with or dissolves in the oil. The liquid is sepd. from the residue and may be used as a fuel or may be distd. for the recovery of hydrocarbons.

Manufacture of oils from coal. JOSEPH TRAUTMANN. Fr. 633,945, May 5,

1927. Instead of condensing the gases from the slow distn. retorts they are sent direct to a hydrogenation plant. Gases such as H_2S are first removed and H , CO , water gas, superheated steam or catalysts in powder form may be added to the gas before it enters the reaction chamber.

Carbonizing coal or briquets. MIDLAND COAL PRODUCTS, LTD., AND C. INGMAN. Brit. 282,511, Oct. 5, 1926. Low-grade gas produced in a primary coal or briquet carbonizing retort is used to carbonize the charge in one or more secondary retorts; the gas is burned and the combustion products are used to superheat steam which is passed through the secondary retorts.

Annular or straight ovens for carbonizing coal, peat, wood, shale or other materials. CHARLES B. WINZER. U. S. 1,678,687, July 31.

Apparatus for manufacture of mixed gas from coal or other carbonaceous material. MORRIS W. TRAVERS and FRANK W. CLARK (to Regenerative Coal Gasification System, Ltd.). U. S. 1,681,313, Aug. 21. A gasification chamber is located beneath and is in communication with a carbonization chamber; air and gas are alternately supplied to the bottom of the gasification chamber; a regenerator communicates with the top of the gasification chamber and with the bottom of the carbonization chamber and a sep. gas-enriching chamber communicates with the regenerator and is provided with an oil-spraying device; some of the gas issuing from the top of the carbonization chamber is forced through the regenerator and into the bottom of the carbonization chamber.

Heating carbonaceous materials with oils, etc. I. G. FARBENIND. A.-G. Brit. 282,691, Dec. 22, 1926. Materials such as coal, brown coal or coal residues from which bitumen has been extd. are heated under pressures of 10–1000 atm. with high-boiling hydrocarbons or their derivs. having no constituents boiling below 300° , such as anthracene oil, mineral or tar oils or their distn. products or products obtained by cracking, destructive hydrogenation or similar processes or synthetic products of high b. p. obtained from H and oxides of C . The products obtained may be used for making lubricating oils or as a fuel for Diesel engines, etc.

Destructive hydrogenation. I. G. FARBENIND. A.-G. Brit. 282,384, Dec. 20, 1926. In the destructive hydrogenation of coal, mineral oils or tar as described in Brit. 249,155 (*C. A.* 21, 1002), when the hydrogenating gases are substantially free from CO or substances leading to its formation, the reaction chamber and such parts of the app. as are exposed to temps. above 300° are formed of materials free from uncombined Fe and Ni , and also from Cu and Ag if S is present. The app. is preferably constructed of Al or of alloys high in Al , or of Cr , Mo , W , V or Mn . The steels V2A and WT2 made by Krupp contg., resp., Cr 20, Ni 7 and C 0.1–0.3%, and Cr 18, Ni 60 and C 0.2% together with Fe may be used as may also the Cr Ni alloy B made by Heraeus contg. Fe 24.2, Ni 60.1, Cr 13.38, and C 0.02%. The alloys used should be freed from impurities in the boundaries of the grains by treatment with moist H .

Gas producer. RENÉ MARION. Fr. 634,365, May 13, 1927. A cylindrical gas producer is provided with a short inner cylinder which the combustion air enters, and the gases formed escape downwardly outside this inner cylinder.

Gas producer. ROBERT M. A. E. CÉZANNE. Fr. 634,396, Aug. 13, 1926; and Fr. 634,399, Aug. 30, 1926. Constructional features.

Gas producer for use on vehicles. DEUTSCHE ERDOL-A.-G. Brit. 282,341, Dec. 20, 1926. Structural features.

Gas-producer construction. GEORGE H. BENTLEY and EDMUND G. APPLEBY. U. S. 1,679,645, Aug. 7.

Gas-producer-conduit system. HARRY M. ROBERTSON (to American Dressler Tunnel Kilns, Inc.). U. S. 1,680,340, Aug. 14.

Production in a gas producer of a solid smokeless fuel. ILLINOIS ANTHRACITE CORP. Fr. 634,447, May 14, 1927.

Purifying gas. WALTER H. FULWEILER (to U. G. I. Contracting Co.). U. S. 1,679,858, Aug. 7. Illuminating gas or other gas contg. H_2S is treated with a soln. of an alk. salt to absorb H_2S as sulfhydrate, and the foul soln. is passed in film form over coke exposed to air for effecting preferential oxidation of the sulfhydrate.

Incandescent material for gas illuminating burners. A. STEPHENSON and ALLEN-LIVERSIDGE, LTD. Brit. 281,800, Sept. 22, 1926. A jet of C_2H_2 or other gas is caused to impinge on a pastille of thoria, lime, strontia, zirconia or the like in such a manner that ignition takes place at the point of contact of the jet with the pastille; the velocity of the jet is sufficient to prevent propagation of the flame towards the nozzle.

Water gas. SYNTHETIC AMMONIA & NITRATES, LTD., AND K. GORDON. Brit. 282,141, Sept. 11, 1926. In gasifying solid carbonaceous materials by reaction with

steam, with or without air or O, heat is applied externally through a heat-resisting metal such as an alloy steel, such as "Staybrite," "Era/A.T.V." or "V2A" steel. Reaction tubes $\frac{1}{2}$ in. in diam. may be heated to 1000° and when air is added a gas may be obtained suitable for NH₃ synthesis after removal of CO.

Water gas, methanol and hydrogen. SYNTHETIC AMMONIA & NITRATES, LTD., and H. A. HUMPHREY. Brit. 282,573, Feb. 22, 1927. Coal is dried at 200–300° by hot combustion gases to which air is added to effect partial oxidation and control the coking properties of the material and is then further subjected to low-temp. carbonization at not above 600° to produce a semi-coke for use in a water-gas generator. The water gas formed may be treated with steam at high temp. to convert the CH₄ into CO and H, or the semi-coke may be heated to a higher temp. before use for generating watergas free from CH₄. The gas mixt. is then passed over a catalyst containing finely divided Fe or other suitable metals at 200–300° to produce higher paraffin hydrocarbons. The residue from this treatment (or the original gas mixt.) is compressed and passed (after sepn. of paraffins and CH₄ if present) over a catalyst such as basic Zn chromate for producing MeOH, or may be treated with steam in the presence of an Fe oxide catalyst at about 500°, converting the CO into CO₂ which is then removed, leaving H which may be mixed with N for NH₃ synthesis.

Plant for making carburetted water gas. C. S. CHRISMAN (to Humphreys & Glasgow, Ltd.). Brit. 282,034, Dec. 10, 1926. A regenerator adapted to store the heat of the carburetted water gas is placed between the superheater and the wash box and is used for preheating the gas-making fluids. Various other structural features are also described.

"Heat accumulator" for generating steam in water gas plants. F. SCHUSSL. Brit. 281,727, Dec. 4, 1926.

Automatic control device for admixture of gas and air for combustion. FREDERICK H. WILLCOX (to Freyn Engineering Co.). U. S. 1,680,833, Aug. 14. An automatic device controls the proportion of gas and air in accord with the CO₂ content of the products of combustion.

Fire lighter. JULES BOUDY. Fr. 633,932, May 2, 1927. A fire lighter is made from naphthalene or naphthalene and resin and sawdust, the melted naphthalene being projected on to the sawdust.

Distilling tar. G. E. BRANDON (to Barrett Co.). Brit. 282,367, Dec. 14, 1926. Tar is distd. by spraying it into the hot gases produced in the carbonization of coal directly after the gases leave the retorts. App. is described.

Coking. R. B. PARKER. Brit. 282,416, Dec. 14, 1926. In the low-temp. carbonization of fuel in an upwardly tapering retort, a zone of combustion is maintained at a temp. of about 425° at the lower end and the residue is continuously removed from the lower end and fresh fuel supplied to the upper end without opening the retort to the atm. Air, steam, CO, or distn. gases may be supplied under pressure to the combustion zone and distn. products are withdrawn from near the top of the fuel column. Auxiliary heating flues may be provided in the walls of the retort.

Coke furnaces. TAR AND PETROLEUM PROCESS COMPANY. Fr. 634,541, May 17, 1927. Constructional features.

Vertical coking retort with interconnected charging and discharging devices. R. B. PARKER. Brit. 282,415, Dec. 14, 1926.

Coking retort oven construction. JOSEPH BECKER (to The Koppers Co.). U. S. 1,678,801–2, July 31.

Coking retort oven construction. JOSEPH VAN ACKEREN (to The Koppers Co.). U. S. 1,678,803, July 31.

Apparatus for cooling coke (partly by inert gas used for heating a steam generator). SOC. ANON. DES FOURN A COKE SEMET-SOLVAY ET PIETTE. Brit. 282,286, May 5, 1927.

Apparatus for recovering heat from coke. SOC. ANON. DES FOURN A COKE SEMET-SOLVAY ET PIETTE. Fr. 633,997, May 6, 1927.

Semi-portable carbonizing plant for making and for semi-coking briquets or balls from sawdust or similar material. J. R. RONGIER (to L. Dupont). Brit. 282,058, Dec. 8, 1926. An app. is described which is adapted for fuel drying, carbonizing and tar recovery.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

F. M. ROGERS

Economic and technical considerations dealing with the cracking process. M. NAPHTALI. *Notiz. chim.-ind.* 3, 277-8(1928).—A review and discussion of present developments. C. C. DAVIS

Survey of cracking plants, January 1, 1928. G. R. HOPKINS. *Bur. Mines Information, Circ. No. 6074*, 14 pp.(1928). E. H.

Cracking topped West Texas crude oil. W. F. FARAGHER AND J. C. MORRELL. *Universal Oil Products Co. Oil & Gas J.* 27, No. 9, 34, 136(1928).—West Texas crude oils from Pecos, Upton, Crane-Upton, and Winkler Counties, when topped and cracked on a non-residuum basis by the Dubbs process, gave an av. yield of 60% N. E. P. gasoline, with 15% bottoms. Recycling of the bottoms gave an additional yield on 7.5% gasoline, or a total of 67.5% based on the topped crude oil, or 49.5% based on the crude oil. The ultimate yield by topping and cracking averages 75%, and blending straight-run with the cracked gasoline gives a product very nearly equal to the Navy gasoline specifications. The av. yield of N. E. P. gasoline obtained when the same topped crude oils were cracked on a residuum basis was 48.5%, leaving 8.7% bottoms, which when recycled gave an added yield of 3.2% gasoline. The total yield based on the crude oil was 39%. The pressure distillates and topped naphtha were refined by plumbite treatments. Tables are given showing the properties of the crude oils and the yields. M. B. H.

Vapor phase cracking in refining oil. D. M. EVANS. *Petroleum Conversion Corp., Texas City, Texas. Oil & Gas J.* 27, No. 8, 146-7(1928).—Commercial operation of the Knox vapor phase cracking process has shown that it produces an antiknock motor fuel unequaled by any gasoline on the market. M. B. HART

Treat cracked distillates with acid in continuous operation. W. R. HOUNSELL. *Houston Oil Co. Oil & Gas J.* 27, No. 3, 201, 205(1928).—A continuous acid-treating plant for cracked distillate is described. M. B. HART

Spontaneous decomposition reactions of berginization—a reaction common to various petroleum hydrocarbons. E. PYHALA. *Petroleum Z.* 24, 308-14(1928).—Expts. with the paraffin-contg. still residues from Grosny, Tscheleken and Surachany petroleum have shown that when the residue is heated slowly at ordinary pressure, a sudden, rapid distn. occurs in two phases, 380-410° and 430-450°, and a large percentage of the paraffins and asphalts in the residue are decomposed without giving pitch or coke. In one instance 71% of the paraffin and 90% of the asphalt were so decomposed. This reaction is common to all petroleum and petroleum residues, and may be regulated, to a certain extent, by regulating the rate of temp. increase. Gases, kerosene, benzene and a residue are produced. The reaction may be used to produce fuel oil with a low f. p. from high-f. p. residues or viscous, pitchy still-ends. Because of the similarity in temp. and charging material, it is thought that this reaction may be of importance in berginization. M. B. HART

A method to determine hydrogen sulfide in petroleum distillates. RUDOLF LIND. *Selig Co., Atlanta, Ga. Nat. Petroleum News* 20, No. 29, 63-6(1928).—A check on the amt. of NaOH soln. used up in the desulfurizing of petroleum distillates consists in titrating an aliquot portion of the spent treating soln. with standard HCl soln., using methyl orange as an indicator, and oxidizing another aliquot portion with H_2O_2 before titrating in the same way. The difference between the two results indicates the amt. of NaOH used up in the treating. In general, about 1.15 or 1.20 mols. of NaOH should be used per mol. of H_2S in the distillate. The same method may be used to det. the amt. of H_2S in gas. M. B. HART

Examination of petroleum distillates. I. Preparation of a standard motor spirit and a standard kerosene. S. T. MINCHIN AND G. R. NIXON. *J. Inst. Petroleum Tech.* 14, 477-92(1928).—In an attempt to produce standard motor fuel and kerosene fractions, high melting point refined paraffin wax from Burmah crude was cracked and the cracked products were fractionated in a Hemple column to (a) distillate to 150° or motor spirit fraction, (b) distillate 150° to 285° or kerosene fraction and (c) residue. The first 2 fractions were then refined with acids and distd. in a Hemple column, cuts being made at each 10°. Sp. gr. at 20°, aniline point, abs. viscosity at 20°, surface tension and n at 20° were detd. for each fraction and the data are given in tabular form. Graphs of the sp. gravities, n s. and surface tensions of the fractions of the motor spirit compared with those of pure hydrocarbons indicate the absence of naphthenes.

and presences of branch chain and normal paraffins. Conclusion: The fractions of motor spirit so prepd. are practically pure paraffins. D. F. BROWN

Composition of petroleum (kerosene and other) fractions. III. Applications of the aniline point, specific gravity and refractive index tests, with properties of individual hydrocarbons. J. A. CARPENTER. *J. Inst. Petroleum Tech.* 14, 446-76(1928); cf. *C. A.* 21, 1702.—Aniline point detns. throughout the b.-p. ranges of kerosene oil are given for paraffins and other classes of hydrocarbons, and for paraffins in the solid wax range. The paraffins were isolated throughout the whole series while naphthenes gave more difficulty. In general all other classes of hydrocarbons can be removed by sulfonation, nitration or solvent extn. or combinations. In the higher ranges these methods are supplemented by freezing. Early fractions of Burmah crude oils contain high proportions of branching-chain paraffins, also naphthenes based on cyclopentane and cyclohexane rings. Simple types of naphthenes have aniline points about 20° below those of their paraffin counterparts while the effects of unsatd. compds. are irregular. Correlation of sp. gr. and *ns* to det. different classes of hydrocarbons proved unsuccessful. Tentative rules for the detn. of unsatd. compds., aromatics, naphthenes and paraffins, based on aniline point detns. in conjunction with acid treatments, are given for kerosene fractions. Applications of the aniline point method are particularly suitable in such problems as identification of kerosenes from different sources, forecast of their burning qualities, detns. required on working out the effect of solvent extractors, decision as to best points at which to cut refined products, detns. of the nature of cracked products and the value of various crude oils from a refining point of view. D. F. B.

Steam temperature control in distillation and in paraffin manufacture. E. BELANI. *Petroleum Z.* 24, 199-201(1928).—The temp. of steam raised in a Benson boiler or similar app., by heating water under critical pressure to its critical temp., may be regulated by means of an app. in which steam entering at the bottom meets a spray of water which in vaporizing cools the steam to the desired temp. Thermometer-controlled regulators at the inlet and outlet automatically adjust the vol. of water in the spray so that const.-temp. steam is produced regardless of fluctuations in inlet temp. M. B. HART

Nature of petroleum filtering earths. P. G. NUTTING. U. S. Geol. Survey. *Oil & Gas J.* 27, No. 6, 138-9(1928).—Filtering earths are silicates which are combinations of bases with the weak silicic and aluminosilicic acids. The filtering action is due to open O and Si bonds which are produced by the removal of H₂O from terminal OH radicals by heating, and takes place by attaching certain alkyl or weakly basic radicals causing either adhesion or a surface action producing insol. org. silicates. Clays of the kaolin type contain no hydroxyl H₂O which can be driven off; hence they are useless as filters. Clays of the bentonite type are poor filters which contain only a little alkali which can be converted to hydroxyl by acid treatment. Any clay contg. either hydroxyl H₂O or terminal alkali radicals which can be converted to hydroxyl by acid treatment makes a valuable material for filtering oils. Theoretically, complex silicates may be split up by fused alkali and the components converted into filter clay by acid treatment. The selective action of filters is readily accounted for by the varying activity of open bonds toward org. radicals retained by bonds of varying strength. M. B. HART

Important investigations under way relative to filtering clay. C. E. KERN. *Oil & Gas J.* 26, No. 50, 126, 128(1928).—A preliminary report of the committee conducting the investigation into the properties of filtering clays, on which the U. S. Geological Survey, National Research Council, National Museum and P. F. Kerr of Columbia University are represented. Clay minerals fall into the kaolin group (which are crystalline and show a mean index of refraction and a low double refraction), the Montmorillonite group (which includes bentonite, fuller's earth and most oil-refining clays, which contain a large proportion of adsorbed H₂O and are cryst., showing a high double refraction and low index of refraction), and clays contg. essential potash (on which little work has been done). The clay minerals show mica-like cleavages and are large in their greatest dimension but in thickness have colloidal proportions, so they have a great area in proportion to their mass which is the principal factor in the adsorption capacity and plasticity. M. B. HART

Influence of physical properties and sizes of filling elements in fractionating columns on the fractionating capacity. K. V. KOSTRIN. *Neftyanoye Khozyaistvo.* 14, 616-26(1928).—A lab. still was charged with 3 l. of Surakhanui crude oil and the rate of distn. kept at 10 cc. per min. Steam distn. with superheated steam and open-fire distns. were made, a distn. column filled with different elements being used. Special care was taken to have all distns. made under exactly the same conditions. Some of them were repeated without showing any deviations. Raschig rings of exactly the same

size made of Al, brass, iron and glass were used in 4 sep. open-fire distns. The 4 distn. curves were identical and also the temps. of heated oil, and vapors. The sp. gr. checked very closely. With Raschig rings of different size an increase in sp. weights and a decrease of temps. were observed with the increase of the size of rings. The Engler distn. of distillates obtained had a tendency to increase the temp. for larger rings. Analogous results were obtained with an open-fire and superheated steam distn. The amt. of oil distd. over was always limited to 150 cc. Conclusion: The nature and shape of filling elements in fractionating columns do not affect the sepn. of fractions. The sepn. of fractions depends on the surface of the elements. A. A. BOERTLINGK

Naphthenic acids from Baku crude oils. D. O. GOLDBERG AND V. L. GURVICH. *Azərbaycan. Neft. Khoz.* 1928, No. 5, 46-51.—Samples were taken from the refinery, at different stages of the distn. process. Kerosene, Solar oil "L," Solar oil "T," machine oil and cylinder oil fraction, and a sample of crude oil were investigated. The oils were saponified with a 2% soln. of NaOH and the soap was decompd. with 10% HCl. The crude acids were treated according to Spitz and Hönig, and their physical consts. were detd. The Balakhanui-Sabunchi crude oil contains 1.06% of naphthenic acids with av. acid no. 202 and av. mol. wt. 277. The acidity of distillates and the % of naphthenic acids increase from light distillate towards heavy and decrease at the end. The max. is with the distillate of sp. gr. 0.882. With the increase of the mol. wt. of acids their sp. gravities decrease; the viscosity, η and I no. increase. The surface tension of naphthenic acids decrease with increase in mol. wt.; the capillarity increases. Naphthenic acids from Balakhanui crude oil are monobasic. Boiling temps. of naphthenic acids do not correspond to b. ps. of fractions from which they are obtained. A. A. BOERTLINGK

Laboratory in refinery operation. I. S. CANNON. Marland Refining Co. *Oil & Gas J.* 27, No. 3, 201-2(1928).—The properties and tests applied to crude oils and products are described. M. B. HART

Concrete-lined storage reservoirs. J. F. HOUGH. Portland Cement Assoc. *Oil & Gas J.* 27, No. 5, 78, 176, 178, 180, 183-4(1928).—Cement used in the construction of oil-storage reservoirs should have a low water-cement ratio, 5 $\frac{1}{4}$ -6 gallons H₂O per sack for low-S crude oils and 5-5 $\frac{1}{2}$ gallons per sack for high-S crude oils. It should be thoroughly mixed, not less than 2 min., with sufficient aggregate to make it workable and be placed over the reinforcement in alternating slabs 4-6 in. thick on the floor and 3-4 in. thick on the sides of the reservoir. A bulkhead should be placed at the edge of each finished slab to provide a joint with the adjacent slab, which must be laid within 12 hours of the completion of the first slab. Cement should be cured 7-10 days by sprinkling or inundating with H₂O to assure a strong, impervious cement structure. M. B. HART

Fifteen men are full operating crew of 8000 bbl. refinery. J. C. CHATFIELD. *Nat. Petroleum News* 20, No. 27, 28-30(1928).—At the Borger refinery of the Phillips Petroleum Co., Hutchinson County crude, which contains enough salt water in suspension to cause severe corrosion of refinery equipment, is sprayed against a bank of tubes through which hot fuel oil runs en route to storage, whereby the water in the oil is vaporized and the salt pptd. while the oil is preheated before passage to the flash tower. The salt is recovered by flushing out with water while the coils are still hot, and the gasoline vaporizing during the treatment is recovered with the steam by passing the vapors to the towers. M. B. HART

Oil well and later developments at Hardstoft, Derbyshire. A. WADE. *J. Inst. Petroleum Tech.* 14, 357-87(1928).—Of the 11 wells sunk at various parts of the British Isles only 2 were successful, these being at Hardstoft in Derbyshire and Darcy near Edinburgh. The first is the only one which has ever looked like a com. proposition. The oil was struck at 3070 ft. and is of very good quality, resembling Pennsylvania crude. Distn. analyses show it to yield 4.5-10% of gasoline, 30-45.5% kerosene and 20-30% of light lubricating oil and wax—S content is about 0.26 to 0.42%. The oil is dark brown in color with green fluorescence. Conclusion: There are com. deposits of oil in England but it would not be profitable at present to try to locate them. D. F. BROWN

The sulfuric acid test for mineral oils. ТУРКЕ. *Petroleum Z.* 24, 314(1928).—Bauer and Baader have proposed a test for transformer and similar oils consisting in detg. the amt. of oil absorbed by concd. H₂SO₄. Other investigators question whether this test gives valuable results, and it is suggested that treatment with acid removes constituents which are of value in increasing the resistance of an oil to oxidation or its lubricating qualities. Much further evidence is needed to decide the ultimate result of the test. M. B. HART

Breaking emulsions in the mineral oil industry. RUDOLF KOETSCHAU. *Kolloid-chem. Technologie* 1927, 23 pp.—The interpretations of Clayton and the classical works of Donnan and Potts are recalled. The measuring methods are enumerated. The methods used in general practice for breaking emulsions are described. A. L. H.

Application of the Lewis' method for the calculation of columns in the mineral oil industry. V. KACHATUROV. *Neftyanoe Khozyaistvo* 14, 627-42(1928). A. A. B.

Shale oil industry in Manchuria. KATSUMOTO ATSUKI. *J. Soc. Chem. Ind. (Japan)* 31, 109B(1928).—A review. K. K.

The vertical steam still applied to fat oil distillation. E. G. ROGATZ. Union Oil Co., Calif. *Nat. Petroleum News* 20, No. 23, 37-9(1928).—A discussion of the equil. relationships in stripping absorption oil brought out by Lewis and McAdams (C. A. 22, 1511). M. B. HART

Volatility test for motor oil both criticized and commended. F. W. BROWN. Emery Manufacturing Co. *Oil & Gas J.* 26, No. 49, 142, 151(1928).—The volatility test for motor oils, suggested by the Cadillac Motor Car Co., consists in detg. the evapn. loss on heating 24 hrs. at 230° F. under conditions similar to those actually occurring in the crankcase, combined with a distn. test. Advantages and disadvantages of this test are discussed. M. B. HART

Diesel fuel-oil specifications vary. G. H. MICHLER. Standard Oil Co. of New Jersey. *Oil & Gas J.* 27, No. 6, 156, 161(1928).—A wide variation in Diesel fuel specifications has come into existence due to the varying requirements expressed by engine builders. This variation tends to increase the cost and difficulty of obtaining fuel of the right quality because of the expense of preparing and storing a no. of different grades for which there is little demand. Suggested specifications include a min. gravity of 24° A. P. I., a max. S content of 1.5% and a min. flash of 150°, closed cup. M. B. HART

Narrow distillation range oils are best for gas absorption. L. D. McLOUTH. Pan American Petroleum Co. *Oil & Gas J.* 27, No. 12, 71, 78, 98, 130-1(1928); *Nat. Petroleum News* 20, No. 32, 54-71(1928).—Tests run on kerosene and gas oils have shown that the superiority of the oils as absorbents is a function of the gravity, viscosity and distn. range of the oil. A general increase in absorption was noted with increases in gravity, narrowing of the distn. range and decrease in the absolute viscosity of the oil. Signal Hill oil fractions were superior to Ventura fractions. Absorption increases with increase in absolute pressure according to Henry's law, with certain exceptions. A "satn. point" is reached, i. e., the point where the partial pressure of the gas becomes equal to the vapor pressure of the components of the oil. It is impossible to absorb gases beyond this point unless the absorption will reduce the vapor pressure of the oil or maintain the partial pressure in equil. with the partial pressure of the gas. An oil from a particular field does not necessarily exert the greatest affinity toward the gas from that field. M. B. HART

Corrosion in oil equipment in West Texas. J. H. DAMERON. *Oil & Gas J.* 27, No. 10, 42, 218(1928).—It is estd. that the annual corrosion toll in West Texas will av. 20% of the original cost of steel tankage. The spongy material removed from the corroded tanks has a high S content, and burns easily, sometimes even igniting spontaneously on short exposure to the outside atmosphere. Lowering the temp. in the tanks and keeping out O₂ seem to help retard corrosion. A protective paint is being developed which is claimed greatly to retard corrosion. M. B. HART

New motor fuel. ANON. *Oil & Gas J.* 27, No. 10, 210(1928).—Sohio, the new motor fuel announced by the Standard Oil Co. of Ohio, is a "high test ethyl motor fuel" having a gravity of 64-66 and end point of 375-390°. Distn. tests indicate that it practically meets government specifications for the domestic aviation grade. The gasoline is made by the Tube and Tank cracking process operating at 1000 lb. pressure and at 825-850° F. and special bubble tower fractionating equipment is used. M. B. HART

Audible spark-advance test method. D. R. ROESCH. Armour Inst. of Tech. *Oil & Gas J.* 27, No. 10, 208-9(1928).—Fuel characteristics detd. at the Armour Inst. of Tech. before conducting routine audibility spark-advance antiknock tests permit checking the specific engine conditions and detn. of the magnitude of such modifying factors as mixt.-ratio, fuel flow while operating with various fuels at a fixed carburetor adjustment, and the effects of the more or less generally accepted antiknock agent benzene. The ratio of air to fuel should be known for practically every internal-combustion engine test. The effect of mixt.-ratio variations on the antiknock index can be evaluated by the use of a graph and it should be detd. A graphical method is described for detg. the benzene equiv. of an unknown fuel. M. B. HART

Light fractions from stabilizer offer new opportunities. F. L. KALLAM. Southwestern Engineering Corp., Los Angeles. *Nat. Petroleum News* 20, No. 30, 21(1928).—The new max. volatility specifications for gasoline make it necessary for natural gasoline manufacturers to weather their product or add fractionating columns to their equipment. The use of a stabilizer permits a finished product from which all the gaseous constituents and C_3H_8 have been removed while C_4H_{10} is retained. The plant gasoline production is decreased but ultimate recovery of high-gravity finished gasoline is raised by the use of a stabilizer, while the light fractions removed can be further processed to liquid C_3H_8 - C_4H_{10} mixts. suitable for domestic gas, and other products. C_3H_8 may find a future use as a substitute for C_2H_2 in cutting, and C_4H_{10} , which is now used for enriching blue gas, may find a use as a refrigerant. One company, by chlorinating residual vapors in the rectifying tower, has marketed CH_2Cl , CCl_4 , $CHCl_3$ and HCl .

M. B. HART

Doctor test now required of natural gasoline. ANON. *Nat. Petroleum News* 20, No. 27, 37(1928).—The revised specifications of the Natural Gasoline Association of America require a doctor test.

M. B. HART

Determining gasoline vapor pressure by the A. S. T. M. distillation test. G. G. OBERFELL, R. C. ALDEN AND L. H. FITCH. Phillips Petroleum Co. *Nat. Petroleum News* 20, No. 31, 58, 62, 64(1928).—Expts. have shown that the A. S. T. M. distn. curve for gasoline furnishes data which, if properly interpreted, give a reasonably close approximation of the vapor pressure of motor fuel as detd. by the Beistle-Prather, Reid and Phillips Petroleum Co. lab. methods.

M. B. HART

Making Skelgas at Panhandle plant. W. T. ZIEGENHAIN. *Oil & Gas J.* 27, No. 7, 166, 177(1928).—Skelgas, which is almost pure C_3H_8 , is made at the Skelly Oil Co.'s Borger, Texas, plant by withdrawing the raw material from the top tray of the fractionating tower in the gasoline system and passing it to a still where it is stabilized by the reduction of pressure. Vapors from the still are returned to the gasoline system while the stabilized product is treated by flowing upwardly through a tower counter-current to hypochlorite soln. The purified material then goes to storage whence it is withdrawn to fill the containers for distribution.

M. B. HART

Factors in design and operation of absorption plants [for natural gasoline]. A. J. L. HUTCHINSON. Engineering, Research and Equipment Co. *Oil & Gas J.* 27, No. 12, 133, 143(1928).

M. B. HART

Magenta plant operates above 600 lbs. pressure. G. REID. *Refiner Natural Gasoline Mfr.* 7, No. 5, 62-4(1928).—The absorption natural gasoline plant of the Natural Gas and Fuel Corp. at Magenta, La., operates at 600-640 lb. per sq. in. The plant operation is described.

M. B. HART

Natural gas used for blending in North Texas. RALPH GOODE. *Refiner Natural Gasoline Mfr.* 7, No. 5, 61(1928).—The use of natural gas instead of air in blending light distillates with natural gasoline has been found to be more economical, to reduce loading and time losses and to produce a thorough and efficient distribution of the natural gasoline. Explosion hazards are virtually eliminated.

M. B. HART

Analysis of natural gas. A. C. ALLEN. Univ. of Kansas. *Oil & Gas J.* 27, No. 4, 131(1928).—Compn. of natural gasoline and its compn. after being run through the gasoline plant as well as the amt. and gravity of gasoline recovered are tabulated.

M. B. HART

Natural gas as fuel for automobiles. C. K. FRANCIS. *Oil & Gas J.* 27, No. 10, 40, 219(1928).—Wild fractions from natural gasoline stabilization manuf. consisting largely of C_3H_8 and C_4H_{10} , or natural gas itself can now be compressed in cylinders and used directly as motor fuel. A special mixing valve must be substituted for the usual carburetor. Tests have shown the fuel to be as satisfactory as gasoline and much cheaper.

M. B. HART

The solubility of gases in liquids. F. E. E. GERMANN. Univ. of Colorado. *Oil & Gas J.* 27, No. 4, 81, 86(1928).—A study of the laws of adsorption of gases in liquids in the presence of colloids and suspensoids indicates that, if there is a greater soly. of gas in oil-permeated sands than in oil alone, the difference in soly. is very slight and may be due only to the difference in conditions rather than to an actual difference in degree of soly. Accurate exptl. methods must be developed to det. exactly what soln. laws are operative underground before detg. the best use to make of natural and repressuring gas.

M. B. HART

Causes of fire in the petroleum industry with methods of prevention. CHRISTOPHER DALLEY. *J. Inst. Petroleum Tech.* 14, 154-73(1928); cf. Epps, C. A. 21, 3737.—A high-class plant and fittings and all-steel, properly grounded storage tanks are the best insurances against fire caused by lightning or other means of ignition. Org. sulfides

and H_2S may react with the Fe of the tank or roof, producing pyrophoric FeS which is dangerous in a dry atm. Static or friction sparks cause little risk of fire but precautions are necessary. Foam is more efficient than CCl_4 as an extinguisher. Burning soot causes a special danger if expelled from the flues of an oil tank during or just after the loading or discharging period when the fire risk is greatest. R. E. SCHAAD

Experiments in viscometry. H. S. ROWELL AND D. FINLAYSON. *J. Inst. Petroleum Tech.* **14**, 402-45(1928).—From the results of viscosity measurements of motor fuels and lubricating oils, data for which are given, the conclusion is reached that viscometry combined with densimetry may be an effective instrument in the analysis or identification of complex carburents, and that there is no abnormal change in the viscosity-temp. curve at elevated temp. D. F. BROWN

Some aspects of the problem of lubricating oils. HENRI WEISS. *École du pétrole et des combustibles liquides, Strasbourg Chimie et industrie* **20**, 3-9(1928).—After a brief outline of the usual processes used for refining mineral oils, W. briefly reviews the tests by means of which the nature of an oil and its lubricating qualities can be ascertained. An investigation of the various methods of detg. the f. p. ("cold test") has shown that the most consistent results are obtained by freezing some of the oil in a capillary tube, cutting the end of the tube, immersing in an alc. bath at a temp. below the f. p., allowing the temp. to rise slowly and noting the pt. at which the oil meniscus begins to rise. Volatility is best detd. by fractional distn. in vacuum (obtained by means of a Hg pump), at the same time passing a current of H through the liquid to insure thorough agitation and also entrainment of the vapors, and using wire gauze to prevent entrainment of particles of liquid. There is a parallelism between the temp. of the first drop of distillate obtained in this way and the fire-point detd. in the usual manner, but much more complete information is obtained from this distn. curve than from the fire-point alone. Very good agreement cannot be expected from viscosity detns. carried out in the same lab. with different instruments, or in different labs. with the same type of instrument. The best results were obtained with the Barbey viscometer and with a well-standardized German instrument (not mentioned by name). The difficulty of devising a satisfactory test for detg. the deterioration of an oil is discussed. A P.-C.

The lubricating properties of mineral and tar oils and their dependence on chemical composition. I. The relations between the lubricating value of brown-coal lubricating oils and their chemical constitution. J. HERZENBERG AND ERIKA JUNGFER. *Braunkohle* **27**, 601-8, 628-33; *Erdöl u. Teer* **4**, 370-3, 387-90, 406-8(1928).—A literature survey and discussion under the general title are given first. The work was done on a machine oil manufd. from brown-coal tar by a process unknown to the writers. The approx. compn. was found to be 24% phenols, 15% resins and 60% neutral oil consisting approx. of 10-12% aromatic, 2% hydroaromatic, 20-25% satd. and 50-60% unsatd. hydrocarbons and 8-10% O and S compds. The usual tests were made on the original oil and after removal of various constituents and on some of the constituents. The essential properties are viscosity and its variation with temp. The lubricating value of the oil was impaired by a high viscosity temp. coeff. and its use as a transformer oil by a high tar-formation no. The temp. coeff. was greatly reduced by removal of the phenols, but the viscosity was then too low to meet machine oil requirements. Removal of the resins by distn. lowered and flattened the viscosity-temp. curve still more. The resins themselves showed a very high viscosity temp. coeff. and an I no. of 25.6. Distn. 3 times over Na, *in vacuo*, for the purpose of removing labile unsatd. constituents, etc., removed 40% of the distillate but reduced the I no. only from 33.3 to 29.4. The viscosity-temp. curve was again lowered, so that it no longer met the requirements for even a light spindle oil, and flattened, and the tar-formation no. fell from 1.48 to 0.14%. This was well within the requirements of a good transformer oil, but the improvement was gained at the cost of too great a material loss. The aromatic hydrocarbons could then be removed as picrates. The satd. hydrocarbons were isolated by removing the total unsatd. and aromatic together from a sep. sample of the Na distillate by means of H_2SO_4 . The unsatd. compds. were then detd. by difference. The hydroaromatics were detd. by catalytic dehydrogenation, over Ni or Al_2O_3 at 380°, and removal of the product as picrates. The properties of these minor constituents are given and discussed. Their viscosities were close together. The less important properties, such as sp. gr., flash, ignition and setting points, and volatility (1 hr. at 100°) which was found strikingly independent of b. p. range, are also covered. The outstanding point is that, in the case of this brown-coal tar oil, at least, which is evidently regarded as typical, the required viscosity is contributed by the phenols, resins and labile unsatd. substances, which are also the constituents responsible for the characteristic objectionable properties, such as gumming, etc. F. S. GRANGER

Natural bitumens, with special reference to bituminous shale. W. ZWIEG. *Petroleum Z.* 24, 243-6(1928).—A peat, resembling cannel coal, which from its appearance and analysis is to be classified with shales rather than with brown coal, has been found in northern Germany. It contains 82.7% volatile matter, and yields 25% dry bitumen on distn. The solid bitumen found in this peat has a very low decompn. point. Gas made from this peat by the von Geipert method has 52.6% of the potential heating power of the peat. Tables give the analysis of the peat, other shales, and gas produced.

M. B. HART

Comparison of the ball and ring method of determination of the softening point of bitumens with Kramer-Sarnow method. B. SHALFEEV. *J. Chem. Ind. (Moscow)* 5, 223-5(1928).—To compare the degree of exactness of the 2 methods, the following 5 substances have been tested on their softening points 5 times each by the ball and ring method and as many times by the Kramer-Sarnow method: natural asphaltic lime, natural asphaltic sand, coal-tar distn. residue, artificial mixt. prepd. from coal-tar distn. residue and oil, petroleum distn. residue (tar). The last-named substance was characterized by the slowness of passage from the semisolid state to the liquid state, whereas the coal-tar residue, on the contrary, passed from the solid to the liquid state within a comparatively short temp.-interval. It could be expected that the data obtained by the 2 methods would differ, not only conforming to the degree of softening temp., but also in accordance with the speed of melting of a given bitumen. Conclusion: The ball and ring method is undoubtedly more exact than the Kramer-Sarnow method. Whereas the deviations of results in the repeated detns. by the first method never exceeded 1°, by the Kramer-Sarnow method the deviations often reached 2°. The figures obtained by the Kramer-Sarnow method were in all cases higher than those obtained by the ball and ring method, and the difference between them (which is usually about 10%) was the greater the higher the softening temp.

BERNARD NELSON

Determination of asphalt in minerals. I. CASMIR. *Petroleum Z.* 24, 315-8(1928).—Asphalt may be detd. in minerals by extn. with C_6H_6 or $CHCl_3$ in a Soxhlet or Graefe app., or by the Prettner method which consists in treating with an ether-HCl soln. and filtering and taking up the residue with benzene. The extn. method gives higher results than the Prettner method because, in the latter, part of the asphalt is converted into a benzene-insol. residue, and S is, to some extent, lost as H_2S ; these two losses are greater than the compensating Cl present in the asphalt after treatment. In both methods the extd. asphalt contains ash in colloidal soln.

Fractional extraction of petroleum hydrocarbons with alcohol. THEODORE A. WERKENTHIN (to Solar Refining Co.). U. S. 1,680,352-3, Aug. 14. See Brit. 254,784 (C. A. 21, 2793).

Cracking oils. UNIVERSAL OIL PRODUCTS CO. Fr. 633,653, May, 2 1927. An app. is described for cracking oils in which the oils circulate in one or several currents through a heated zone and pass from there into a reaction zone. An incondensable

gas which may be the gas produced by the cracking itself is introduced into the reaction zone (cf. *C. A.* 22, 3288).

Cracking oils. UNIVERSAL OIL PRODUCTS CO. *Fr.* 633,652, May 2, 1927. In cracking oils the condensate is submitted to a second distn. to sep. the lighter fractions and the residue from this distn. is submitted to a final "cracking." The second distn. is carried out while the condensate is still warm.

Cracking petroleum oils. GUSTAV EGLOFF (to Universal Oil Products Co.). U. S. 1,679,208, July 31. In a continuous process, a stream of oil is heated to a cracking temp. in a heating zone such as pipe coil in a furnace and the heated oil is then passed into an enlarged reaction chamber in which a body of liquid oil accumulates and vaporization occurs; liquid and vapors are withdrawn from the chamber and the vapors are dephlegmated, portions of the residual liquids are removed from the system and the remaining portions of the residual oil are united with uncondensed gases produced in the process and this mixt. is returned directly to the vapor space of the reaction chamber. An app. is described. Cf. *C. A.* 22, 2461.

Refining petroleum oils with "doctor solution." ROBERT L. HALLETT (to National Lead Co.). U. S. 1,678,984, July 31. Pb chloride is dissolved in a NaOH soln and the resulting soln. is used to remove S from petroleum oils.

"Artificial petroleum." HIROTARO NISHIDA and KEIICHI SHIMADA. U. S. 1,680,908, Aug. 14. Hydrocarbons of rubber waste are destructively distd. in the presence of a natural bleaching earth such as dehydrated "Japanese acid earth." The product is fractionated.

Oils resembling petroleum by destructive distillation of rubber. H. NISHIDA and K. SHIMADA. *Brit.* 282,565, Jan. 22, 1927. See U. S. 1,680,908 (precedin. abstr.).

Cracking hydrocarbon oils. WILLIAM S. HADAWAY, JR. (to The Texas Co.). U. S. 1,678,728, July 31. An app. is specified in which a multi-tubular heat-exchange device is mounted longitudinally within a vertical cracking chamber; oil is introduced into the bottom of the exchanger and discharged from its upper end into the cracking chamber. An agitator is also mounted within the cracking chamber and connections are provided for drawing off liquid from the bottom and vapors from the top of the chamber.

Production of light hydrocarbons from heavier hydrocarbons. DAVID G. BRAND (to Doherty Research Co.). U. S. 1,681,321, Aug. 21. Heavy hydrocarbon material such as fuel or crude oil is preheated under pressure to about 230° by means of heat transfer from vapors undergoing condensation and then passed to a cracking zone in which it is brought into contact with hydrocarbons at a temp. of about 350–425° to effect cracking of the heavy hydrocarbons. Vapors produced are withdrawn and the heaviest fraction of the vapors is condensed and returned to the cracking zone; the next heavier fraction of the vapors is condensed and this portion is preheated by heat transfer from the vapors and is passed in fine streams through a heating zone at a temp. of about 540–600° and thence into the cracking zone; the remaining condensable portion of the vapors is condensed and the portion still remaining uncondensed is passed through the heating zone in contact with the previously mentioned fraction passing through this zone and these materials are thence passed together through the cracking zone. An app. is described.

Distilling hydrocarbon oils. FRANK F. WELLMAN (to Kansas City Gasoline Co.). U. S. 1,680,580, Aug. 14. A hydrocarbon oil is subjected to a cracking temp. and pressure on one zone and the vapors produced in this zone are fractionated in a second zone and are further condensed and fractionated in a third zone to which heavier fractions are refluxed for redistn. Vapors produced by redistn. are separately fractionated in a fourth zone and from this light vapors are led off and condensed; the heavier fractions from the fourth zone are returned to the third zone, and all the heavier fractions from the third zone are returned in liquid phase into the first zone. An app. is described.

Fractional distillation of hydrocarbon oils. JOSEPH W. LEWIS, JR. (to Atlantic Refining Co.). U. S. 1,680,421, Aug. 14. Vapors of the oil are passed countercurrent to and in contact with reflux oil; a portion of the reflux oil intermediate the lightest and heaviest fraction is withdrawn and this portion is passed countercurrent to and in contact with steam to remove constituents of low b. p. and yield an intermediate fraction of higher flash point; the other portion of the reflux oil is continued countercurrent to the vapors in an earlier stage of the fractionating system. An app. is described.

and labile unsaturation of volatile hydrocarbons. M. OKOSHI. *Brit.* 282,541, Nov. 12, 1926. Characteristic objects of hydrocarbons carried by natural gas, air or other gases are adsorbed by silica

gel, C, fuller's earth or other suitable materials at a low temp. and at either atm. or higher pressure and cooling is effected by sudden expansion of previously compressed gases. Another part of the compressed gas may be employed for cooling a condenser in which the adsorbed substances are recovered after distn. An app. is described.

Lining for oil stills. ORRIN E. ANDRUS and SUNE HERMANSON (to A. O. Smith Corp.). U. S. 1,680,276, Aug. 14. A thin sheet of corrosion-resisting alloy such as a Cr alloy is secured against the inner wall of vessels such as oil stills by elec. spot welding.

Inclined tubular oil-cracking still. WILLIAM T. HANCOCK and JOHN W. HANCOCK. U. S. 1,680,541, Aug. 14. Free balls are placed in the still in spaces between disks of an agitating device mounted on a shaft extending through the still along its axis.

Apparatus for removing carbon deposits from petroleum stills. BUTLER P. CRITENDEN and ALVIN C. KILLINGER (to Beacon Oil Co.). U. S. 1,680,322, Aug. 14.

Apparatus for distilling oil shale or similar material in a bath of molten metal. C. A. SPOTZ. Brit. 281,769, Sept. 9, 1926.

Distilling oil shale. OSKAR TETENS (to the Firm Record Cement-Industrie G. m. b. H.). U. S. 1,678,751, July 31. The shale is burned in mixt. with non-combustible calcareous material such as limestone or marl in a water-jacketed combustion zone in the jacket of which steam is produced; a column of the mixt. is maintained above and below the combustion zone and the oil distd. is deducted with the ascending hot gases. A raw material suitable for use in the manuf. of hydraulic cement is discharged as a residue. An app. is described.

Desulfuration and hydrogenation of mineral oils, etc. BERGIN COMPAGNIE VOOR OLIE EN KOLEN CHEMIE. Fr. 632,509, July 7, 1926. Addn. to 559,787. In a process for the simultaneous desulfuration and hydrogenation of heavy mineral oils or their products of distn. or the distn. products of coal using alkali metals in the presence of H, the starting material is given a preliminary treatment with solid KOH, or metallic oxides, under pressure of H at a high temp.

Dephlegmators for oil vapors. DANIEL PYZEL (to Simplex Refining Co.). U. S. 1,678,823, July 31. Structural features are specified of a plurality of dephlegmators connected with each other so that condensate from one passes into the top of another.

Heat exchange apparatus suitable for condensing oil vapors. EDOARDO M. SALERNI (to E. M. S. Industrial Processes, Ltd.). U. S. 1,680,641, Aug. 14.

Furnace for heating oils, etc. C. F. DE GANAHL. Brit. 282,287, May 31, 1927.

Water trap for gas wells. EDWIN L. POSTON (one-half to Daniel E. Alexander). U. S. 1,680,255, Aug. 7.

Apparatus (with an annular carbonizing chamber) for carbonizing wood or similar materials. HENRI HENNEBUTTE and EDOUARD GOUTAL. U. S. 1,680,613, Aug. 14.

Apparatus for purifying gasoline used in "dry cleaning" (by sedimentation and chemical treatment). FREDERICK G. LONDAGIN. U. S. 1,681,002, Aug. 14.

Device for purifying oil used in lubricating internal-combustion engines. DAVID F. ZOOK. U. S. 1,680,716, Aug. 14. The oil is heated, and is subjected to sedimentation and filtration.

Lubricant. STANDARD DEVELOPMENT CO. Fr. 634,442, May 14, 1927. A lubricant is made by adding to a hydrocarbon oil possessing lubricating properties, less than 1/2% by wt. of soap, and heating the mixt. to a temp. above 176°, but not above the b. p. of the oil.

Emulsions of asphalt or other materials. LESTER KIRSCHBRAUN. U. S. 1,679,475, Aug. 7. A colloidal emulsifying agent such as bentonite or clay is mixed with such a proportion of the end product of an emulsion of the same general character as that desired as to form a paste, liquid heated bituminous material is added and is agitated to effect dispersion. An app. is described.

Acetic acid. HERMANN SUIDA. Fr. 634,202, Mar. 14, 1927. To obtain concd. AcOH in the distn. of wood, the mixt. of distd. gases is freed from tar and then passed through a column contg. an extractor for AcOH of higher b. p. and not miscible with water such as cresol. The water and MeOH are not condensed at the temp. of the column.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

The structure of cellulose. JOHANNES SCHEIBER. *Farbe u. Lack* 1928, 334-5, 346-8.—Review. G. G. SWARD

The colloidal properties of "pure" cellulose. P. P. VON VEIMARN. *Kolloid-Z.* 44, 212-8(1928).—The resistance of many types of cellulose fibers to the dispersing

action of hot salt solns. is not a characteristic property of the cellulose itself, but must be referred to the effect of the surface coating of the fibers. Thus, cotton is but slowly dispersed in a NaSCN soln. boiling between 142–50°, and the gel formed on cooling the sol contains fibers. Extn. with petroleum ether increases the ease of dispersion. Exhaustive extn. with petroleum ether and xylene renders the material as readily dispersible as pure filter paper, and gives a clear gel. A cellulose cannot be considered as actually "pure" until this resistant surface coating is entirely removed; to do this, the fibrous structure must be completely destroyed. The procedure necessary to purify a "fibrous" BaSO₄ ppt. is cited (cf. C. A. 3, 393; 22, 1712). There should be but one "pure" cellulose, and this should in theory be obtainable in macro-cryst. form. Guignet cellulose approaches such a "pure" cellulose in its properties. R. H. DOUGTRY

The extraction of cellulose by the chlorine process. B. OGLIETTI. *Notiz. chim.-ind.* 3, 279–80(1928).—A crit. review of the development and the present status of the Cl process leads to the conclusion that in the present condition of the chem. industry, the Cl process can be applied economically only in special cases where the raw materials do not give satisfactory results on a large scale with other processes, or where, because of their low com. value more money can be put into the process. Chestnut residues fulfil these conditions, for with the aid of the Cl process in modified form, a white cellulose can be obtained which can be used with satisfactory results in paper. The utilization of these residues for the production of cellulose can and should alleviate the dependence of Italy on foreign sources of cellulose. C. C. DAVIS

Cellulose resources. I. The annual wood crop. GEO. M. ROMMEL. *Ind. Eng. Chem.* 20, 494–6(1928).—A survey of the sources of cellulose material in the U. S. made for the U. S. Dept. of Agr., this phase covering wood. The annual growth increment of a no. of common American trees is estd. in cu. ft. and in tons per acre per year. The growing rates of the northern and southern woods are contrasted and the favorable outlook for the latter is pointed out, especially for newsprint production, if some effective means can be discovered for eliminating the resins. The com. possibilities of wood wastes for pulp are also discussed and the likelihood of some other cellulosic raw material, such as cornstalks eventually replacing wood. II. Cellulose from field crops. *Ibid* 587–91; cf. C. A. 22, 2837. The possible utilization of cornstalks for cellulose (pulp) and various factors of growth, yields per acre, methods of cultivation, etc., are considered. Conversion of cornstalks to pulp offer one means of combating the corn borer. The pulping possibilities of various cereal straws, flax, hemp, soy beans, cotton waste and bagasse are considered and deemed favorable. C. E. CURRAN

Cellulose esters. I. Depolymerization and mechanical properties of the nitrates. H. OKADA. *Cellulose Ind.* (Tokyo) 3, 285–96(1927).—Having worked out a method for prepg. regular nitrocellulose films under standardized conditions, O. has studied the relations between viscosity and mech. properties. Various types of cellulose in the form of cotton, celluloid, tissue paper, bleached sulfite wood pulp and sulfite pulps specially purified with lime and Na₂SO₃ were subjected to preliminary treatments calcd. to induce depolymerization while avoiding definite hydrolysis and oxidation. Treatments comprised heating at 145° and 125° with water, dil. alkali, and glycerol; treatment with NaOH under mercerizing conditions; regeneration from alkali cellulose after various aging periods; regeneration from viscose and in the form of viscose silk; treating nitrocellulose with water under pressure. These modified celluloses were nitrated under identical conditions, the viscosities of the nitrated products were detd. in 1% acetone soln. and films were made 0.10–0.12 mm. thick from the ether-alc. solns. Over a wide range of relative viscosities from 126 down to 2.5 the tenacity of the films was almost const. at 15 kg. per sq. mm., and the crumpling resistance was rather less const. at about 200. The influence of depolymerization of the cellulose, while very marked on the viscosity, had a nearly negligible degrading effect on the mech. properties. Only at a very advanced stage of depolymerization, with reduction of the viscosity figure below 2, was a very sudden breakdown of the mech. resistance of the nitrocellulose film recorded, obviously brittle products being thereby produced. B. C. A.

Lignocellulose of Victorian mountain ash (*Eucalyptus regnans*). HOWARD W. STRONG. *J. Soc. Chem. Ind.* 47, 87–90T(1928).—In detg. the cellulose in *E. regnans* the sample is extd. with an alkali, preferably by boiling with 1% NaOH for 1 hr. Alkali solns. of greater concn. give low yields of both cellulose and α -cellulose. In reacting with Cl the amt. forming HCl is double that combining with lignin, which with this material is 7.5 to 8% of the total. C. E. CURRAN

Helianthus argophyllus. Commercial possibilities as indicated by its composition. K. S. MARKLEY AND W. T. SCHREIBER. *Ind. Eng. Chem.* 20, 636–7(1928).—The cellulose content of *H. argophyllus* is 46.5%, lignin 13.38%, the balance being pentosan

derivs. which yielded furfural up to 13.34%. Pulping tests gave a yield of 34.4%. The competition of this material with wood as a source of cellulose is not deemed likely but it compares favorably with bagasse, cotton and grain hulls, which are frequently proposed as sources of cellulose.

C. E. CURRAN
The manufacture of cellulose sausage casings. W. F. HENDERSON. *Ind. Eng. Chem. (News Ed.)* 6, No. 12, 12(1928).—Descriptive of the production of artificial sausage casings from cotton linters by the viscose process.

C. E. CURRAN
Carbon disulfide in viscose manufacture. JOHANN EGGERT. *Chem.-Ztg.* 52, 289-90(1928).—Industrial hazards are discussed. CS₂ is highly volatile; the most efficient ventilation cannot remove all the vapors from some parts of the plant. The vapors form explosive mixts. with air, which may be ignited by steam pipes or overheated bearings. It may also explode in the absence of O. CS₂ in Fe tanks may form extremely explosive pyrophoric Fe sulfide, especially if moisture is present. CS₂ is a poison; it can be absorbed through the skin as well as the lungs, producing a variety of symptoms. Individuals vary greatly in sensitiveness to the poison, women being especially sensitive. The best practice is to exercise all possible precautions, and to select the most resistant workmen for the most exposed positions.

R. H. DOUGHTY
A semi-chemical pulping process. J. D. RUE, S. D. WELLS, F. G. RAWLING AND J. A. STADL. *Chem. Met. Eng.* 34, 611-3(1927); cf. C. A. 20, 3807.

C. E. CURRAN
Shortening the cooking time in the Mitscherlich (sulfite pulping) process. LEO FRIEDLÄNDER. *Papier-Fabr.* 26, 335-7(1928).—By using a liquor-tube heat-interchanger instead of the customary steam coils in a vertical Mitscherlich digester, it should readily be possible to double the rate of heating, with a consequent important decrease in total cooking time. Such a heater if properly designed would be readily cleanable, and would not interfere with the mech. operation of the digester.

R. H. D.
Chemistry of wood. III. Composition of Tsuga and Momi. Y. UEDA AND T. YOSHIDA. *Cellulose Ind. (Tokyo)* 3, 297-8(1927); cf. C. A. 22, 3293.—Air-dried samples of Japanese pulp woods *T. sieboldii* and *Abies firma* on analysis gave: cellulose 48.71%, 45.24%; lignin 21.53%, 25.74%; furfuraldehyde (as pentosans) 4.69%, 6.26%, and resins (as benzene ext.) 2.17%, 2.26%, resp. These woods bear a close similarity in compn. to the Kabafuto spruce, but showed an exceptional difficulty in the chlorination process of analysis due to the strong affinity between the cellulose and the lignin in these woods; this has an important significance in the pulping process. Because of their compact structure these woods are only suitable for pulping by chem. methods.

B. C. A.
Paper pulp from logging waste in the Douglas fir region. A. H. HODGSON. U. S. Forest Service. *Ind. Eng. Chem.* 20, 819-21(1928).—A survey in the Oregon, Washington and British Columbia logging areas shows that about 20,000 feet board measure per acre (all species) is left in the woods, a waste wood source of some 8,200,000 cords per year. This consists of western hemlock, Sitka spruce, white fir, Douglas fir, cedar and pine. The possibilities of utilizing this for pulp and the steps already taken in that direction are pointed out.

C. E. CURRAN
The importance of hydrogen-ion concentration in pulp and paper manufacture. H. T. S. BRITTON. *Ind. Chemist* 4, 49-52(1928).—An exposition of the influence of p_H in various pulp and paper making processes and benefits to be secured by its control. The list includes sulfite pulping, bleaching and sizing.

C. E. CURRAN
The measurement of p_H and its application in the paper-mill. RUDOLF LORENTZ. Tech. Hochschule, Tharandt. *Papier-Fabr.* 26, 365-70, 427-33(1928).—The theory of p_H detns., buffers and methods of measurement are considered. It is important that the p_H of fresh and waste waters for process use be known. Since most mill waters contain buffer substances, actual acidity (p_H) is a better control than potential acidity (titration) in most cases. To obtain good results in sizing with rosin, it is necessary that the p_H be 7 or over before the size or alum is added (cf. Shaw, C. A. 19, 3590).

R. H. DOUGHTY
Drying with warm air in the pulp and paper industry. ERNST BLAU. *Papier-Fabr.* 26, 393-4(1928).—Air in positive circulation at controlled temp. is the most efficient means for drying pulp, boards and similar material. Mech. arrangements in use are mentioned.

R. H. DOUGHTY
Technology of straw-pulp production during the last 25 years. G. ODRICH. *Papier-Fabr.* 26, 132-3. WILLI SCHACHT. *Ibid* 333-5(1928).—Controversial, regarding the merits of the Braun (monosulfite) process.

R. H. DOUGHTY
Kraft pulp and paper from Pinus insignis. L. R. BENJAMIN, J. L. SOMERVILLE, R. B. JEFFREYS AND W. E. COHEN. *Australia Council Sci. Ind. Research Bull.* No. 35, 5-32(1928).—Lab. expts. in the cooking of insignis pine by the sulfate process showed

that the best results were obtained by using about 21% alkali (of which 30% was Na_2S) and 100 lbs. steam pressure. These pulps tested by the ball-mill method gave bursting strength values of 1.3+ per lb. per ream, $25 \times 40-500$. Reuse of the black liquor was found to affect adversely the tearing strength of the pulps. These results were tried on a com. scale with essentially the same results as lab. expts. and subsequent paper-making tests indicated that the pulp was equiv. to standard Swedish kraft in all respects. The economics of manuf. this product in Australia is discussed. C. E. C.

Paper pulp from Australian timbers. L. R. BENJAMIN. *J. Council Sci. Ind. Research (Australia)* 1, 65-73.—A descriptive summary of expts. in the pulping of eucalypts and other timbers indigenous to Australia, as well as grasses, sedges, etc., by the standard processes. The eucalypts were successfully reduced by the soda, sulfite, sulfate and ground-wood methods, the latter yielding best results with immature timbers. Especially good kraft pulp was produced from insignis pine. The possibility of eucalypt. newsprint paper is discussed. C. E. CURRAN

Grinding of immature eucalypts for mechanical pulp and possibilities of manufacturing newsprint in Australia. L. R. BENJAMIN. *Australia Council Sci. Ind. Research Bull.* No. 31, 5-38(1927).—Expts. were made relative to the grinding of swamp gum (*E. regnans*), brown stringybark (*E. obliqua*), blue gum (*E. globulus*), gumtop stringybark (*E. delegatensis*), mountain ash (*E. regnans*) and silvertop (*E. sieberians*) light-colored pulps being produced without difficulty. These were combined with varying proportions of eucalypt sulfite in papers approximating newsprint grade. Best results were obtained from 70% eucalypt sulfite and 30% eucalypt ground-wood pulp. It is shown that this combination is economically feasible in Australia. C. E. C.

Aluminum sulfate in paper manufacture. H. ROSCHER. *Papir-J.* 16, 108-10 (1928).—Sizing of paper cannot be accomplished as effectively with acids and acid salts as with alum, since this phenomenon depends not only upon the degree of acidity but also upon the fact that alum hydrolyzes, producing the colloidal hydroxide, which is absorbed on the fiber, thus fixing the size and color. C. E. PETERSON

The mechanism of the loading of paper. KATSUMOTO ATSUKI and MITSUO NAKAMURA. Univ. Tokyo. *Cellulose Industry* 3, 5-8; *Chem. Zentr.* 1927, II, 190-1; cf. *C. A.* 22, 163.—The loading of paper with Chinese clay (particle size $3-6\mu$, loss on ignition 3.39%) was investigated. The dried clay, which was neutral to phenolphthalein and to methyl orange, was agitated with comminuted paper pulp and water; after coming to equil. the mass was filtered through a sieve through which only the clay passed, 25 cc. of the filtrate was pipetted off and the dry residue detd. From the decrease in concn. the quantity of clay retained by the paper could be detd. This quantity increased with the concn. of clay in suspension up to 3-4%, beyond which more clay did not result in increased retention by the paper. After addn. of starch paste to the reaction mixt., considerably more clay was retained, and this was also increased by the addn. of viscose when the latter was pptd. with acids after the reaction, otherwise the alkali of the viscose reduced the retentive capacity. The addn. of glue did not influence the retentive capacity. By the simultaneous addn. of $\text{Al}_2(\text{SO}_4)_3$ and NaHCO_3 the quantity of clay retained was increased. Increasing the concn. of paper did not materially influence the proportion of clay retained. By a finer subdivision of the paper, the retention increased to a max when the paper was divided into its individual fibers. The retention of clay by paper pulp is explained as occlusion of the clay by the paper, for since clay and fiber are both negatively charged, the clay is not in a colloidal state and therefore the elec. and surface adsorption can be only insignificant. With diminishing H-ion concn. (pH 2.0-13.0), the quantity of clay retained by 1 g. of paper pulp decreased from 1.57 to 0.46 g. C. C. DAVIS

Parchment, glassine and imitation parchment papers. FRITZ HOYER. *Kunststoffe* 18, 154-6(1928).—Parchment (pergament) paper is produced by a suitable surface treatment with chemicals. Glassine (pergamyn), on the other hand, is produced by appropriate beater treatment. Imitation parchment (pergamentersatz) is produced similarly to glassine but lacks its transparency, glassiness, water and greaseproof qualities etc., the similarity to glassine being attained by high calendering and being only superficial. All of these papers are used for wrapping of food stuffs and greasy materials. Their manuf. is described. BONIFANT HAMILTON

Vegetable and synthetic tannins (GERNGROSS) 29. Lignin and cellulose. V. Methylcellulose (FREUDENBERG, BRAUN) 10. Chemical structure of α -lignin (KLASON) 10. Mechanism of the saponification of cellulose esters of higher fatty acids (SAKURADA) 2. Apparatus for drying paper (Brit. pat. 282,032) 1. Dome construction for stills

for paper pulp digesters (Brit. pat. 281,928) 1. Boiler composition and disincrustant (U. S. pat. 1,679,037) 14.

Extraction of cellulose. SOC. FRANÇAISE DES CELLULOSES "BARBOU & Co." Fr. 634,402, Sep. 14, 1926. In a process for leaching cellulose material with Na_2SO_3 , fresh Na_2SO_3 is added to the residual lye and this is used again until a strength of about 20° Baumé is reached, when it becomes economical to recover the org. matter and Na_2SO_3 contained therein.

Cellulose derivatives. LEON LILIENFELD. U. S. 1,680,224, Aug. 7. Alkyl esters of cellulosexanthic acids are obtained by acting on a cellulose xanthate with an alkyl ester such as Et_2SO_4 , EtI , EtBr , Me_2SO_4 or MeI . The products may be used for manuf. of artificial threads, films, plastic masses or coatings or for the manuf. of other compds. or derivs. of cellulose.

Cellulose acetate. EDWARD S. FARROW, JR. (to Eastman Kodak Co.). U. S. 1,679,966, Aug. 7. Cellulosic material such as cotton linters is treated with an aq. HCl soln. of over 25% strength and free from oxidizing agents, at room temp. for 2-6 hrs. The action is stopped before the phys. appearance of the material is changed and the treated material is then acetylated, *e. g.*, by use of Ac_2O . The preliminary treatment with HCl serves to facilitate acetylation.

Cellulose esters. I. G. FARBENIND. A.-G. Brit. 281,927, April 19, 1927. Cellulose acetates and other cellulose esters are prepd. by treating cellulose with a small proportion of H_2SO_4 (suitably 0.5-1.0%) in the presence of a diluent such as HOAc or other aliphatic acid, then adding Ac_2O or other suitable esterifying agent to effect partial esterification of the cellulose, and subsequently adding addnl. H_2SO_4 , with or without more of the esterifying agent, to complete the esterification. The starting material may be cotton, wood pulp, hydrocellulose, oxycellulose or slightly nitrated cellulose.

Cellulose ethers. CHAUNCEY U. PRACHEL and LEONARD E. BRANCHEN (to Eastman Kodak Co.). U. S. 1,679,943, Aug. 7. An acid such as HCl or HOAc is permitted to react on cellulose ethers such as water-insol. ethylcellulose until the viscosity characteristics of the ether are lowered by at least one-third.

Acetylating cellulose. CLAUDE DIAMOND (to Courtaulds, Ltd.). U. S. 1,681,103, Aug. 14. Cellulose which has been treated with NaOH is prepd. for acetylation by treatment with a phenol, *e. g.*, with PhOH or *m*-cresol, which serves to facilitate the acetylation.

Viscose. R. SAJITZ and E. POTT (TRADING AS CHEMISCHE FABRIK POTT & Co.). Brit. 281,679, Nov. 30, 1926. In the manuf. of viscose, salts of aromatic sulfonic acids are added, especially salts of those acids which are alkylated in the nucleus such as naphthalenedi- and -trisulfonic acids alkylated in the nucleus or sulfonic acids of hydroaromatic compds. of the phenanthrene and anthracene series. If the salts are added to the mercerizing lyes, the temp and duration of ripening of the alkali cellulose does not require such exact adjustment; or, the salts may be added at a later stage, and avoid need of exact adjustment of the compn. of the coagulation bath.

Artificial silk. NAAMLOOZE VENNOOTSCHAP NEDERLANDSCHE KUNSTZIJDEFABRIEK. Brit. 282,326, Dec. 17, 1926. See U. S. 1,672,365 (C. A. 22, 2663).

Artificial silk. JEAN H. BRÉGEAT. Fr. 633,969, May 5, 1927. To recover volatile products in the spinning of artificial threads, the loom is entirely covered by a tunnel with necessary means of access. The unevapd. solvents are recovered by damping the threads after their passage through the drawplate.

Apparatus for making artificial-silk filaments. GRUNERT & GIANNETTI (to K. Grunert). Brit. 282,670 Dec. 24, 1926. Air or other gas is bubbled through the coagulating liquid to carry off the larger bubbles present in the liquid and leave only smaller bubbles which have no injurious effect on the formation of the filaments.

Alloy for jets for making artificial-silk filaments. WILLIAM P. DREAPER. U. S. 1,680,598, Aug. 14. See Brit. 260,672 (C. A. 21, 3461).

Softening vegetable fibers. SIDNEY D. WELLS. Fr. 633,801, May 3, 1927. Vegetable fibers such as wood, straw or grass are softened by treatment with a soln. of CaCO_3 and S under high pressure and at a temp. of about 145°. Cf. C. A. 21, 2063.

Sizing fibers. HUBERT L. BECHER (to The Agasote Millboard Co.). U. S. 1,678,720, July 31. See Can. 275,625 (C. A. 22, 1243).

Threads or films, etc., from cellulose nitrate or acetate or other cellulose derivatives. ERNST BERL. U. S. 1,679,850, Aug. 7. A soln. or "gelatin" of nitrocellulose or other cellulose deriv. is treated with a pptg. bath contg. both salts and solvents, *e. g.*, H_2O , alc. and NaCl , NaOAc or $\text{Ca}(\text{NO}_3)_2$.

Hollow artificial filaments. ERSTE BÖHMISCHE KUNSTSEIDEFABRIK A.-G. Brit. 282,687, Dec. 21, 1926. In making hollow filaments as described in Brit. 258,582 (C. A. 21, 3129), the added solid or liquid substance is eliminated from the filaments by subjecting them to a vacuum and if necessary also heating them; *e. g.*, when a petroleum fraction b. 200° is added, a pressure of 10–20 mm. and a temp. of 75–90° is suitable for its elimination.

"Wool-like" cellulosic derivatives from xanthates. WILLIAM HARRISON. U. S. 1,680,021, Aug. 7. The unstable insol. xanthate formed by the combined action of a caustic alkali or alk. sulfide and CS₂ on cellulosic material is subjected to the action of HNO₃ or other suitable mild oxidizing agent which does not completely split off the CS₂ previously combined with the cellulose and which converts the unstable insol. xanthate into a stable compd.

Oxidizing carbohydrate xanthates. WILLIAM HARRISON. U. S. 1,680,020, Aug. 7. A dil. soln. of viscose contg. not more than 5% of cellulose is treated with an aq. soln. of HNO₃ in the presence of a "weak acid" such as HOAc or other acid which is not derived from a N oxide. Cf. C. A. 22, 164.

Treating "black liquor" from soda and sulfate cellulose manufacture. ERIK HÄGGLUND. U. S. 1,680,540, Aug. 14. See Brit. 273,267 (C. A. 22, 1854).

Utilizing acid waste sulfite liquor for the production of yeast. GUSTAF O. W. HEIJENSKJÖLD (to Aktiebolaget Basta). U. S. 1,680,043, Aug. 7. An app. and process are described in which acid waste sulfite liquor may be neutralized to "at least the neutral point," filtered and then added together with other desired nutrient substances for yeast, to a wort of high sugar concn. in which yeast is being propagated with aeration.

Pulp from wood. FRANCIS G. RAWLING. U. S. 1,679,682, Aug. 7. Wood chips are treated with an aq. soln. of Na₂SO₃ and NaHCO₃ or other suitable Na salt of a weakly ionized polybasic acid, at a temp. of 100–150°, unabsorbed liquor is removed from the wood and the latter is subsequently treated with SO₂ at 100–160°. Cf. C. A. 21, 3743.

Continuous cooking of wood pulp or other fibrous materials. THOMAS L. DUNBAR (to Chemipulp Process, Inc.). U. S. 1,679,336, July 31. The material is fed through a series of cooking chambers arranged end to end and is cooked in each of the chambers by a cooking liquor such as acid sulfite soln. The material in the first chamber is subjected to hydrostatic pressure and, in the succeeding chambers, to higher temp. and super-atm. pressure. An app. is described.

Washing cooked straw. DEWITT C. AMERINE. U. S. 1,678,718, July 31. In treating straw to prep. it for making strawboard or paper, it is cooked in a lime-S compn. in a rotating vessel while treated with steam under pressure and washing water is subsequently supplied against the steam pressure while continuing the rotation of the vessel; the steam pressure is reduced and a portion of the liquid is withdrawn from the vessel. An app. is described.

Paper-making apparatus. C. MOES. Brit. 282,620, Dec. 24, 1926.

Paper-making apparatus. RALPH E. HEISEL (to Paper Machinery Corp.) U. S. 1,679,523, Aug. 7.

Paper-making apparatus. JAMES K. DARBY (to Frank C. Trowbridge). U. S. 1,679,854, Aug. 7.

Paper-making apparatus. ARTHUR BELLEMARE U. S. 1,680,277, Aug. 14.

Pulp for paper manufacture. DINSHAW R. NANJ1. U. S. 1,679,441, Aug. 7. See Brit. 280,629 (C. A. 22, 3300).

Suction roll for paper-making apparatus. EARL F. BERRY (to Beloit Iron Works). U. S. 1,679,598, Aug. 7. Structural features.

Flexible metallic cloths for paper-making apparatus. R. KASTNER. Brit. 282,685, Dec. 24, 1926. Structural features.

Apparatus for beating paper pulp. HOMAR D. MARTINDALE. U. S. 1,680,912, Aug. 14.

"Beating engine" for paper pulp. LEO SHILICK. U. S. 1,679,056–7–8–9, July 31.

Fiber board from liquid pulps containing digested cane material. ROBERT A. MARR. U. S. 1,680,896, Aug. 14. Various mech. and manipulative features are specified.

Coating paper with wax. ELIE W. LABOMBARDE. U. S. 1,681,350, Aug. 21. Mech. features.

De-inking paper. ALAN R. LUKENS (to The Richardson Co.). U. S. 1,680,949, Aug. 14. A fibrous pulp such as that formed from printed paper is soaked in an alk. soln. such as Na₂CO₃ soln. in the presence of a Na sulfonate or other suitable sulfonic acid compd. and the pulp is washed with water without the use of further addn. of soap or fatty acid.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

Annual report of explosives division, Department of Mines (Canada) for 1927. G. OGILVIE. *Separate* 23 pp.—The various activities of the inspectors in the enforcement of the Act are described in detail. Among accidents at factories was one on Mar. 4, at Brownsburg, P. Q., of a bundle of delay-action elec detonators which exploded while being waterproofed by dipping, and which, by influence, fired upwards of 10,000 other detonators in the building. It is thought that the accident originated in an unusually severe blow on the bundle of detonators while shaking them in the dipping barrel to remove the excess fluid. A second accident, in manufacture, on Oct. 14, was the explosion of approx. 10,000 0.22 primed shells *en masse* as an operator was shaking shells into a loading-plate. The shells were rim-fire and it was found difficult to clean the walls of the shells completely from the priming composition. There is recorded a case of spontaneous decompn. of a mass of sawdust saturated with nitroglycerin, produced in the cleaning out of a sump with sawdust. During a severe ice storm a magazine on the shore of Lake Erie was wrecked and its explosive contents were discharged into the lake. An account is given of the recovery, inspection and reconditioning of the explosives and detonators. Many instances of mislaid and abandoned explosives and detonators are given. The table on "Playing with detonators" records, with descriptions, 25 accidents through which 4 small boys or girls were killed and 29 others seriously injured while 19 others, including 1 man, were injured while playing with explosives. Many of the detonators and some of the samples of explosives were "found" where they had been mislaid or abandoned.

CHARLES E. MUNROE

New apparatus for automatically detecting combustible vapors (benzene, ether, etc.) in air. BIBEL. *Zentralbl. Gewerbehyg. Unfallverh.* 14, 291-3(1927); *Chimie et industrie* 19, 1067(1928).—The presence of combustible or explosive vapors in air can be detected by an app. similar to the one used for detg. CO₂ in flue gases. The method is based on detg. the relation between the viscosity and d., the viscosity being measured by means of Poiseuille's law by the resistance to its passage through a capillary tube, and the d. being measured by Bunsen's law by the rate of flow through a small aperture. The app. used in practice comprises a metal recording pressure gage and a suitable elec. warning device to tell when the danger point is reached. It is claimed that 0.02% C₆H₆ can be detected.

A. PAPINEAU-COUTURE

Estimation of products formed during the storage of powder SD. LECORCHE AND JOVINET. *Mem. poudres* 23, 69-78(1928).—A study of the products formed in powder stored for 4 years at 50°. The powder had the compn. CP₂ (cotton powder No. 2) 66%, nitroglycerin 27%, centralite 7%. It was dissolved in NaOH and steam-distd., the study being concerned with those products which are volatile with steam. Characteristic tests are given for the detection of ethylphenylnitrosamine and volumetric methods for the detn. of centralite in the presence and absence of nitrosamine and ethylphenylnitrosamine. The centralite is reduced in acid or alk. soln. with Zn to ethylaniline, converted to the hydrochloride and titrated with NaOH and methyl orange. Corrections are given for the errors involved.

A. J. PHILLIPS

The limits of inflammability of fire damp in atmospheres which contain black damp. H. F. COWARD AND F. J. HARTWELL. *Safety in Mines Research Board* No. 19, 11 pp.(1928).—Though self-propagating inflammation is possible in any mixts. of CH₄ with atms. consisting of air to which there has been added (a) 25%, or more, of CO₂; or (b) 38.5%, or more, of N, the amt. of black damp (CO₂ + N) that must be mixed with air to form an extinctive atm. for CH₄ flames lies between these percentages according to the proportions of CO₂ and N in the particular sample of black damp. There is a rapid fall in the value of the upper limit of inflammability of CH₄ as a diluent is added to the air, which is mainly due to a reduction of the O-content of the atm. The comparatively slow rise in the value of the lower limit in atms. containing up to 20% of diluent gas indicates that the addition of moderate amts. of either N or CO₂ would not appreciably diminish the danger of a fire damp explosion underground. C. E. M.

The electric ignition of fire damp; alternating and continuous currents compared. R. V. WHEELER. *Safety in Mines Research Board* No. 20, 18 pp.(1928).—The variables upon which the igniting power of a "break-flash" or "momentary arc" depends were investigated separately. In default of an absolute measure of the energy in a break-flash, its relation igniting power has been expressed in terms of the circuit (in amperes) flowing in the circuit at the moment of interruption, which yielded a spark just capable of causing ignition. The igniting-current for a given mixt. of CH₄ and air varies di-

rectly with the volatility of the metal at the spark-gap, being lower the lower the b. p. of the metal. Other conditions remaining const., the igniting current for a given mixt. of CH_4 and air is lower the more rapid the break of circuit, the smaller the area of contact at the moment of break of circuit, the lower is the igniting current required for a given mixt. of CH_4 and air under otherwise identical electrical conditions. There is no simple universal law connecting the value of the igniting-current with the inductance of the circuit, but the relationship varies with the mechanical conditions under which the sparks are produced. Under one particular set of conditions, the relationship could be expressed by $Li^{1.4} = k$, meaning that the energy required in the circuit before break ($1/2 Li^2$) to produce the igniting sparks was nearly const. In general, particularly with highly self-inductive circuits the amt. of current in the circuit is of far greater importance than the impressed voltage if its value is comparatively low as regards the igniting power of the flash produced on breaking the circuit. The character of the current supply, whether continuous or alternating, does not materially affect the incendiary of break-flashes.

C. E. MUNROE

Some economic aspects of dust explosion and fire prevention. DAVID F. PRICE. Bureau Chemistry and Soils. *Separate* 6 pp.(1928).—A review of accomplishment with detailed examples in starch factories and pulverized-fuel systems showing methods of procedure by which prevention has been accomplished.

C. E. M.

Danger of explosion or fire from persulfates. WALTER ROTH. *Ind. Eng. Chem. News. Ed. 6, No. 7, 5-6*(1928).—Such apprehension has been felt that in water transportation it has been required that persulfates shall be packed in "strong, tight, securely closed kegs of galvanized iron" and stowed on deck. Tests were made of persulfates alone and mixed with sweepings from wooden floors by Professors Agde and Alberti. The detonation and percussion tests gave negative results. With the mixt. with sweepings a charring of the org. matter only was observed at 160° . It is recommended persulfates be packed for shipment in wooden kegs paraffined to prevent penetration of moisture through crevices and that such kegs be stowed below deck. CHARLES E. MUNROE

Explosives. HAMBURG DYNAMITE-A.-G. VORM A. NOBEL & Co. Brit. 282,631, Dec. 21, 1926. Solns. of one or more nitrates of solid multivalent alcs. such as sorbitol, mannitol and arabitol in nitroglycerin, nitroglycol or like materials are gelatinized with nitrocellulose and may be also mixed with other ingredients such as sawdust and NaNO_2 . Examples are given.

• **Priming mixture for explosives.** ARLIE W. SCHORGER (to C. F. Burgess Laboratories, Inc.). U. S. 1,681,259, Aug. 21. A solid deflagrating oxide of C suitable for use in priming mixts. is obtained by known methods of making "graphitic oxide." This product may be mixed with Hg fulminate, trinitrotoluene, picric acid, etc.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Simplification applied to color fashions. WALDON FAWCETT. *Am. Dyestuff Rept.* 17, 504-5(1928).—A concert of action is suggested within an industry to the end that colors will "take turns" in their presentation to the public. L. W. RIGGS

Production of bright colors on textiles. XXXVI. RAFFAELE SANSONE. *Am Dyestuffs Rept.* 17, 376-80(1928); cf. C. A. 22, 2843.—Mordanting and padding processes are described. XXXVII. *Ibid* 484-6.—Methods of management of differently filled padded fabrics are given. XXXVIII. *Ibid* 505-8.—The work of filling and sizing is shown with reference to special machinery. L. W. RIGGS

Colored fabrics. ABEL CAILLE. *Chimie et industrie* 19, 1139-50(1928).—A historical review of the development of the industry from early days. A. P.-C.

Action of light on dyed colors. F. SCHOLEFIELD, EVA HIBBERT AND C. K. PATEL. *J. Soc. Dyers Colourists* 44, 236-7(1928).—The fading product of Ciba Blue 2B dyed on cotton was isolated; it appears to be dibromoisatin. The fading product from cotton dyed with methylindigo gave the reaction for o-methylisatin. L. W. R.

Use of buffers in the determination of color by means of titanium trichloride. I. AMARANTH, PONCEAU 3R, and ORANGE I. O. L. EVENSON AND D. T. MCCUTCHEN. *Ind. Eng. Chem.* 20, 860-2(1928).—Accurately to det. the color content of dyes by titration with TiCl_3 , the correct buffer must be used for each dye. For Amaranth, Na citrate, NaHCO_3 or potassium antimony tartrate is suitable. For Ponceau 3R,

Na citrate or NaHCO_3 may be used. For Orange I, Na citrate, NaHCO_3 or the tartrates (except potassium antimony tartrate) may be used. T. S. CARSWELL

Colored reserves under sulfur dyes. HENRI FLEISCHER. *Bull. soc. ind. Mulhouse* 94, 195-7 (1928). Sealed Note 1941, Oct. 23, 1909.—The process, consisting essentially in fixing basic dyes on Zn ferricyanide in presence of Zn tungstate, is carried out as follows: jig the fabric in $\text{K}_3\text{Fe}(\text{CN})_6$ soln. (35 g. per l.), print with the color paste (contg. a basic dye dissolved in PhOH , a soln. of Zn tungstate in a suitable org acid, Zn Cl_2 , kaolin and gum senegal), dry, steam 4 min. in a Mather-Platt at $102-8^\circ$, dye with S dyes in a jig, wash with cold water, then with 5° Bé. H_2SO_4 at 50° R., again with cold water and finally with soap at 50° R. The washing should be carried out immediately after dyeing. There is formed a ppt. of Zn tungstate which is washed, filtered, pressed and dissolved in a cold soln. of tartaric acid (7 parts acid to 14 parts H_2O), giving a soln. of $46-8^\circ$ Bé. after filtration. A no. of formulas are given. Report. VALENTIN SCHWARTZ. *Ibid* 197-8.—Reserving under S dyes by fixing basic dyes with ferro- or ferricyanide has long been known, but the fastness is not satisfactory. By working in presence of Zn tungstate there is formed a double lake with the ferrocyanide and Zn tungstate, which greatly improves the fastness to soap. The process possesses the serious drawback of greatly weakening the fabric at the points where the reserve is applied in consequence of the presence of large amounts of tartaric acid. This could easily be prevented by adding Na tungstate to the jiggling soln. and then printing a reserve consisting of the dye, ZnCl_2 and kaolin. A. PAPINEAU-COUTURE

Colored reserves under sulfur dyes. L. GOUBYRIN. *Bull. soc. ind. Mulhouse* 94, 367-70 (1928). Sealed Note 1933, Sept. 28, 1909.—In obtaining colored reserves under S dyes, use may be made of the power of resorcinol- CH_2O to fix basic dyes; but when this is carried out in the usual manner (applying the resorcinol to one side of the fabric and then printing with the color contg. CH_2O) diazo dyes cannot be used. These dyes can be used by first applying β -naphthol- CH_2O to the fabric and then printing with a paste contg. the dye, resorcinol, ZnCl_2 , etc. On steaming 4 min., there is a double decomposition, the CH_2O combining with the resorcinol probably through the presence of ZnCl_2 . A no. of formulas are given. Report. VALENTIN SCHWARTZ. *Ibid* 370-1.—The process is a happy combination of the previously known processes for reserving diazo dyes by means of β -naphthol and basic dyes by means of resorcinol- CH_2O . The colored reserves obtained in this way (as shown by the samples accompanying the note) are generally good (though some obtained with basic dyes are rather dull), and possess good fastness to soap. A. PAPINEAU-COUTURE

Derivatives of indophenol sulfur dyes derived from carbazole and its substitution products. ED. JUSTIN-MUELLER. *Bull. soc. ind. Mulhouse* 94, 185-6 (1928). Sealed Notes 2126 and 2138 of Nov. 6 and Dec. 22, 1911.—On treating indophenol S dyes derived from carbazole (e. g., Hydron Blue R and Hydron Blue G) in soln. in 66° Bé. H_2SO_4 with a mixt. of equal vols. H_2SO_4 and HNO_3 , pouring into cold water, washing, filtering and neutralizing, nitro derivs. are obtained which, on dyeing, give shades different from those of the original dyes. On prolonging the nitration, nitro derivs. of different shades are obtained. On dyeing in alk. hyposulfite, the NO_2 groups are reduced to NH_2 , so that these dyes can be either diazotized and developed, or else coupled. These shades are perfectly fast to washing, but have but a poor fastness to Cl. Report. A. RASOUMEFF. *Ibid* 186-7.—J.-M. does not check the rise in temp. due to the nature of the reaction, which may be of considerable importance in view of the vulnerability of the characteristic radicals of S dyes. As regards conversion of the nitro derivs. obtained into amino derivs., which can be either diazotized and developed, or else coupled, the latter treatment has already been suggested for certain S dyes contg. the required radicals. Otherwise, no anteriority was found. A. PAPINEAU-COUTURE

Effect of sulfur dioxide on azo dyestuffs and a proposed new standard test for fastness to stoving. A. T. KING. *J. Soc. Dyers Colourists* 44, 14-8 (1928); cf. following abstr.—Alky. has a strong influence on the sensitivity of azo dyes on wool to the action of SO_2 . The present standard of fastness to stoving has no relation to the effect of SO_2 when there is present in the dyed material sufficient alkali to form NaHSO_3 with the SO_2 absorbed. This sensitivity is due to the formation, within the limits of alky., of a definite stable compd. (azo-sulfite) of the azo dyestuff with NaHSO_3 . The azo-sulfites are usually very different in color from the original dyestuffs. With dyestuffs of reputedly good fastness to stoving, which readily form an azo-sulfite under favorable conditions, such conditions may be realized (1) in actual stoving, (2) through accidental exposure of wool or yarn-dyed material to SO_2 , and (3) through the presence of residual sulfite from previous processes. These 3 topics are discussed at length. Complete de-

tails for a new standard test for fastness to stoving are reserved for a future communication.

L. W. RIGGS

Chemical effects of the natural sulfur in wool on the fading of azo dyestuffs. A. T. KING. *J. Soc. Dyers Colourists* **44**, 233-6 (1928); cf. preceding abstr.—Wool is a source of SO_2 aside from external contamination. The azo dyes affected by SO_2 may be classed as follows: (1) those which are reduced and do not reform on treatment with NH_3 and (2) those which form azo-sulfites reconvertible to the original dye with NH_3 . The relative fastness to light of azo dyes and their azo-sulfites was detd. for Crystal Scarlet Orange II, Fast Red A and Acid Orange GG, and showed much greater fading for the azo-sulfite. The actual quantity of S present in the wool necessary to produce a fading effect in the dyed material when oxidized to SO_2 is less than 2% of the av. S content of wool.

L. W. RIGGS

Note on the catalytic action of certain substances on the removal on indigo dyes by means of nitric acid. N. WOSNESSENSKY. *Bull. soc. ind. Mulhouse* **94**, 187-9 (1928). Sealed Note 1924, Sept. 2, 1909.—The possibility of removing indigo dyes by means of HNO_3 instead of chromates has long been known, but has not been applied industrially because of the necessity of using H_2SO_4 at a concn. of 29° Bé. and at a temp. of 70°. The concn. and temp. can both be reduced by operating in presence of N oxides (e. g., by adding NaNO_2), which apparently exert a catalytic action. Acceleration of the oxidation of indigo by HNO_3 in acid medium can also be accelerated by Zn, Al or Cu powder, and to a less extent by K_2SO_3 , NaHSO_3 and hyposulfite; they do not seem to act as true catalyzers, but rather give rise to what Ostwald calls conjugate reactions. **Note on the use of flavanthrene and of thioindigo red B for removal on indigo blue.** *Ibid* 189-90. Sealed Note 1925, Sept. 2, 1909.—Because of their fastness to soap, light and oxidizing agents, flavanthrene dyes and thioindigo dyes seem particularly suitable for colored removals on indigo; but as they must be applied in reducing medium they could not be used in the presence of chromate, and it is the NaNO_2 process which has allowed of their use for this purpose. It is carried out by printing the fabric with a mixt. of dye, alkali, rongalite and NaNO_2 , steaming (during which operation the leuco deriv. formed penetrates into the fabric), allowing to stand overnight to facilitate oxidation of the indigo (which gives brighter shades), passing through 30° Bé. H_2SO_4 at 75° and rinsing. Thioindigo Scarlet R similarly gives a brick-red, which is considerably dulled, possibly because of incipient nitration of the dye. **Nitroso- β -naphthol dyes: removal on indigo blue.** *Ibid* 190-1. Sealed Note 1940, Oct. 18, 1909.—The NaNO_2 process of removal has enabled W. to obtain a transparent olive on indigo blue, which could not be obtained with chromates and albumin dyes. The dyes which can be used with the NaNO_2 process can also be used in conjunction with *o*-Nitroanisidine Red and Dichloro-aniline Yellow by printing the nitrosoamines of those bases and the NaNO_2 soln. after prepg. the goods with NH_4OAc according to W.'s Sealed Note 1916. **Report.** LOUIS PAULUS. *Ibid* 191-2.—Tests carried out by P. showed that: (1) NaNO_2 acts as a catalyzer in the removal on indigo by NaNO_3 , enabling the concn. and temp. of the H_2SO_4 to be reduced. (2) NaNO_2 is better than sulfites, etc., which were used for the same purpose. (3) Vat dyes can be used in the NaNO_3 process, giving beautiful and fast illuminations on indigo ground. (4) The removal pastes on indigo blue with NaNO_3 , together with Fe or Cr nitrate and nitroso- β -naphthol, with or without basic dyes (prepd according to formulas in Note 1940), give beautiful olive and brown shades on indigo.

A. PAPINEAU-COUTURE

Production of thioindigo scarlet on the fiber. MORAND BAUMANN. *Bull. soc. ind. Mulhouse* **94**, 372-3 (1928). Sealed Note 1955, Nov. 24, 1909.—Thioindoxyl or thioindoxylcarboxylic acid easily combines with isatin to give thioindigo scarlet, and B. produces the reaction directly on the fiber in dil. alk. soln. Best results are obtained with hydroxythionaphthencarboxylic acid dissolved in borax (α -hydroxythionaphthene must be dissolved in Na_2CO_3 , in presence of which combination takes place too rapidly) and isatin- NaHSO_3 (instead of free isatins in Na_2CO_3). **Report.** M. BATTEGAY AND J. SCHMID. *Ibid* 374.—Note 1954 treats of the synthesis of thioindigo red on the fiber by oxidizing a suitable soln. of oxythionaphthene or of hydroxythionaphthencarboxylic acid which was covered by Kalle's D. R. P. 184,956, of Oct. 28, 1905. The prepn. of thioindigo scarlet on the fiber as described in Note 1955 differs from Kalle's D. R. P. 229,369, of Feb. 13, 1909, according to which a soln. of intermediate is used, previously prepd. by condensation of isatin with hydroxythionaphthene in alc. soln. A. P.-C.

The fixation of basic dyes on complex inorganic salts. MARIO MICHELS. *Bull. soc. ind. Mulhouse* **94**, 344-57 (1928); cf. C. A. 22, 1477, 2468.—M. considers that the fixation of basic dye is due to the action of certain radicals in the mordant, the active radicals being: SiO_2 , CrO_3 , MoO_3 , WO_3 , UO_2CN , $\text{M}(\text{CN})_x$, SCN , $\text{M}(\text{SCN})_x$.

When the active radicals are combined in the form of simple compds. which are sol. in H_2O , they react with basic dyes to give ppts. which are slightly sol. in H_2O and can in many cases be crystd.; when the active radicals are combined in the form of simple compds. which are insol. in H_2O , they do not fix basic dyes, but they can acquire fixative or mordanting properties if their mol. undergoes a slight change giving rise to traces of complex substances. Sol. complex salts contg. active radicals react with basic dyes to give ppts. which are slightly sol. or insol. in H_2O . Insol. complex salts contg. active radicals, if they are very finely divided or in colloidal aq. soln., can fix insol. basic dyes forming lakes which are fast to water and to light. These various points are supported by means of examples.

A. PAPINEAU-COUTURE

New effects on silk-cotton fabrics. PAUL DOSNE. *Bull. soc. ind. Mulhouse* 94, 358(1928). Sealed Note 1386, April, 4, 1903.—Effects different from those obtained by union silk-cotton fabrics are obtained by spinning cotton with waste silk. **Report.** LOUIS PAULIS. *Ibid* 358-9.—Spinning of such yarn is expensive, as the material must be carded and it is difficult to obtain a perfectly uniform mixt. No anteriority was found.

A. PAPINEAU-COUTURE

The mordant RS, an acid in dyeing. VITTORIO CASABURI. *Boll. ufficiale staz. sper. ind. pelli mat. concianti. supplemento tecnico* 6, 49-55(1928).—The new mordant RS is a liquid of dark reddish color; its density is 22° Bé. and its reaction is almost neutral. It is employed in dyeing chrome leather, the chromed hides being first treated with the mordant and then with an aniline base.

L. L.

Modern emulsifying agents. S. R. TROTMAN. *Chem. Trade J.* 83, 49-51(1928).—A lecture in which are discussed methods for the prepn. and use of emulsions as wetting agents, as vehicles of insol. dyestuffs, as agents for silk processing and as agents in the application of azoic colors to wool and silk.

L. W. RIGGS

Bleaching and soupling Italian yellow gum silk yarn. NOEL D. WHITE. *Am. Dyestuff Rept.* 17, 512-4(1928).

L. W. RIGGS

The proper bleaching of silk and rayon. THOMAS F. HUGHES. *Am. Dyestuff Rept.* 17, 496-8(1928).—Methods for large-scale operation are given.

L. W. R.

Absorption of acids by wool. I. Summary of the literature. H. WILKINSON AND A. G. TYLER. *J. Soc. Dyers Colourists* 44, 241-5(1928).—A review with 42 references to the literature.

L. W. RIGGS

Discussion of soap in its relation to the scouring of wool. II. Potash or soda soaps—which? PROCTER & GAMBLE. *Textile Research Div. Procter and Gamble Wool Scouring Bull.* No. 2, 1-17; cf. *C. A.* 22, 2063.—Claims for the superiority of K soaps rest on tradition and prejudice rather than on scientific proof. Na oleate has been shown to be equal, and in many respects superior to K oleate. The exptl. results of this study may be summarized as follows: (1) Na oleate exceeds any textile demand for soly. In its flaked form it dissolves far more rapidly than potash gel. Moisture is absorbed equally by the two when on wool. (2) Na soap hydrolyzes less and loses less alkali through absorption by wool; it therefore has a less harmful effect on the softness, elasticity and strength of wool. (3) Na soap rinses better than K soap because of its greater soly. and less absorption. (4) The fatty acid emulsions are equally stable for both soaps since this stability depends on the low titer of the oil stock. (5) K soap, both in flake and gel form, becomes rancid in a much shorter period than Na soap. K soaps are 10 to 15% more expensive than Na soaps.

L. W. RIGGS

Ingenious new chart devised for simplifying the solution of cotton cloth analysis problems. A. S. MARK. *Textile World* 74, 694-5(1928).—A logarithmic chart is described for rapidly computing the count, the wt. of cloth in yards per lb., or the lbs. of yarn per yard of cloth. The value of such charts in the textile industry is stressed and the development of other similar charts urged.

RUBY K. WORNER

Practical method and new gage developed for measuring quantity of nap on Canton flannel. F. W. CARTLAND. Westinghouse Elec. & Mfg. Co. *Textile World* 74, 425-6, 431(1928).—A new gage and a definite method of operation have been developed to meet more closely the following requirements: (1) The gage should be a dead-weight type of instrument of rigid construction. (2) The load should be applied directly to the pressure foot in such a way as to maintain uniform frictional forces as small as possible. (3) The pressure foot should be self-aligning for very small displacement forces. (4) The dial gage should be well made, have a stroke of at least $\frac{3}{4}$ in., and be calibrated in thousandths of an inch. (5) The instrument should be equipped with some suitable device which would allow the raised pressure foot to descend to the specimen at a uniform speed, independent of the operator. The procedure outlined offers a more exact means of detg. the quantity of nap on a napped flannel than the present method of vis-

ual comparison. It makes possible also a comparison of several different flannels without bringing them together. A picture of the gage is included. RUBY K. WORNER

The setting of crepe twist and the shortening due to twisting. WARREN P. SEEM. *Textile World* 74, 699, 703, 705(1928).—The soaking and steaming methods for "setting the twist" are described. The effect of the pliability of the raw silk thread, wt. and style of flyers, speed and tension on thread, temp. and humidity in the spinning room, and tension and moisture in the thread when redrawing on to the shipping bobbin have a decided influence on the shortening of the finished thread. Since the method of throwing crepe varies in different plants, shortening values to be detd. mathematically are suggested as a possible acceptable standard. A mathematical treatment of this subject by Andrews is presented.

Processes and chemicals used to render fabrics water-repellent and waterproof. HERMAN E. WENNSTROM. *Textile World* 72, 2185-7(1927).—Fabrics may be rendered water-resistant by the application of certain water-repellent impregnants, or they may be rendered waterproof by the application of certain mixts. which not only render the fibers waterproof but also leave an impervious coating on the whole surface of the fabric. Several methods for rendering fabrics water-repellent or waterproof are discussed.

Investigations on mineral oil stains (on textile fabrics). R. F. MENNECKE, LUCIEN PICARD, VICTOR SILBERMANN, TH. BAUMANN AND PAUL DE CHAMBRIER. *Bull. soc. ind. Mulhouse* 94, 241-67(1928).—A detailed report is given of exhaustive investigations on the removal of stains caused by spinning oils. With the grades of mineral oils generally used, the stains can be removed when fresh by boiling 6 hrs. in a Mather-Platt with a soln. of NaOH, Na₂CO₃ and rosin, at the end of 3 months' exposure to the atm. at about 10-5° the stains begin to become indelibly fixed on the fiber. Mineral oils which were specially purified and deparaffined by the Pechelbronn Company could still be removed at the end of 8 months; but it is doubtful if such oils could be economically prepd. on a commercial scale. Use of a mixt. of mineral oil and colza oil instead of pure mineral oil greatly facilitates removal of the stains. Scheurer and Wallach suggested (1911) use of spinning oil contg. 75% of colza oil, but it is now found that 33-60% is sufficient according to the quality of mineral oil used.

The "Zair" process. Treatment of animal fibers with ozone. REGINALD B. BROWN. *J. Soc. Dyers Colourists* 44, 230-3(1928).—Many tests of the process were described, some of the tests being on a reduced factory scale. It is suggested that the process may acquire a com. importance.

Percentages of moisture and soluble matter in substances used by North Carolina mills (GRIMSHAW) 28. Tests on ash, grit, color, pasting points and lasting qualities of starch (GRIMSHAW) 28. VI. The liquid crystal state of natural silk (VEIMARN) 2. Report of the fiber expert to the Government of Bengal [on jute] (McLEAN) 15. Rubberized fabric driving belts (Brit. pat. 282,271) 30.

RISTENPART, E.: *Die Praxis der Bleicherei*. Berlin: Verlag von Krayn. Reviewed in *Tiba* 6, 845(1928).

Dyes. BRITISH DYESTUFFS CORPORATION, LTD., W. D. ROGERS, H. EVANS and W. F. A. ERMEN. Brit. 282,481, Sept. 13, 1926. Brominated pyranthrone are made by brominating pyranthrone in chlorosulfonic acid soln. or suspension in the presence of I (suitably at 80-85°, followed by pouring the mixt. on to ice and subsequently boiling the dye with weak alkali).

Dyes. BRITISH DYESTUFFS CORP., LTD., and H. W. MOSS. Brit. 282,548, Dec. 7, 1926. Trisazo dyes which dye cotton bluish black shades which can be diazotized on the fiber and developed with usual components such as β -naphthol or *m*-tolylene-diamine are made by coupling a diazotized nitroamine or acyldiamine of the benzene series such as *p*-nitroaniline or *p*-aminoacetanilide, with or without other substituents, with a *peri*-aminonaphtholsulfonic acid such as H acid in an acid medium, further coupling in an alk. medium with a tetrazotized diamine of the benzene series such as tetrazotized benzidine, and again coupling the resulting diazodisazo compd. with α -naphthylamine or its 6- or 7-sulfonic acids or their mixts. The nitro group is reduced or the acyl group removed by hydrolysis at any stage after the first coupling. Several examples are given.

Dyes. I. G. FARBENIND. A.-G. Brit. 282,107, Dec. 13, 1926. *o*-Hydroxyazo dyes are converted into more easily sol. dyes by treatment with chlorosulfonic acid or its esters. The reaction may be effected in the presence of pyridine, dimethylaniline or other tertiary base, and the products may be treated in substance or on the fiber with metallic salts such as those of Cu or Cr. Several examples are given.

Dyes. I. G. FARBENIND. A.-G. Brit. 282,409, Dec. 14, 1926. Acid wool dyes of reddish tint are produced by reaction of 1-amino-4-bromo-2-anthraquinonesulfonic acid with a *p*-aminoacetanilide substituted in the acylamino group by a Me, Et or other alkyl group, a benzyl group or a hydroaromatic group. The reaction may be effected in the presence of CuSO_4 and aq. NaHCO_3 .

Dyes. I. G. FARBENIND. A.-G. Brit. 282,629, Dec. 23, 1926. Vat dyes giving orange dyes from an alk. hyposulfite vat are produced by treating Bz, Bz'-diarylpyranthrones with condensing agents, *e. g.*, with MnO_2 and H_2SO_4 while cooling and sepg. the resulting dye by pouring into water.

Dyes. I. G. FARBENIND. A.-G. Fr. 632,501, Dec. 24, 1925. Addn. to 578,690. Condensation products are prep'd. from dibenzanthrone or dibenzanthronyl or their derivs. not substituted in the Bz2-Bz2'-positions by the action of an aliphatic or aromatic acid chloride or COCl_2 , or phthalic anhydride in the presence of a condensing agent such as AlCl_3 . The products dye cotton in shades of blue. Halogenated products are obtained by carrying out the process in an atm. of halogen.

Dyes. I. G. FARBENIND. A.-G. Fr. 633,869, May 4, 1927. A yellowish green azo dye which can be readily transformed into a lake is made by coupling diazotized 4-chloro-2-nitroaniline with the *p*-chloroanilide of acetoacetic acid.

Dyes. I. G. FARBENIND. A.-G. Fr. 634,198, Feb. 19, 1927. Vat dyes of the 2-thionaphthene-2'-indolindigo series are prep'd. by condensing the 3-hydroxy-1-thionaphthenes substituted in the 4, 6 and 7 positions by 3 halogen atoms, or by an alkyl group and 2 halogen atoms, or by 2 alkyl groups and 1 halogen atom, with the α derivs. of isatin, or its substitution products or homologs. Thus, 4-methyl-6,7-dichloro-3-hydroxy-1-thionaphthene is condensed with 5, 7-dichloroisatin 2-chloride. The product dyes cotton from the vat in reddish violet tints fast to boiling with Na_2CO_3 .

Dyes. I. G. FARBENIND. A.-G. Fr. 634,232, Apr. 19, 1927. Azine dyes are prep'd. by condensing 3-arylamino-1,8-naphthosultams or their derivs. with nitroso aromatic derivs., or by submitting to simultaneous oxidation the 3-arylamino-1,8-naphthosultams with *p*-diamines or *p*-aminophenols or their homologs or derivs. Thus, 3-phenylamino-1, 8-naphthosultam-6-sulfonic acid is condensed with 4-nitrosodimethylaniline-HCl or 3-(4-tolylamino)-1,8-naphthosultam-6-sulfonic acid and 4-amino-dimethylaniline-3-sulfonic acid are oxidized together. The first gives a reddish violet and the second a violet on wool in an acid bath.

Azo dyes. I. G. FARBENIND. A.-G. Fr. 633,811, May 3, 1927. Azo dyes, which dye cellulose ethers and esters in intense shades are prep'd. by coupling diazo compds. of the benzene or naphthalene series or their derivs. not contg. S or COOH groups, other than picramic acid, either with phenols substituted in the *p*-position and not contg. S or COOH groups or with their homologs capable of being coupled in the *o*-position. Examples are given.

Azo dyes. I. G. FARBENIND. A.-G. Fr. 633,812, May 3, 1927. A yellow dye particularly suitable for dyeing acetate silk is obtained by coupling diazotized *p*-nitroaniline with 1-nitro-2,4-diaminobenzene.

Azo dyes. I. G. FARBENIND. A.-G. Fr. 634,620, May 18, 1927. The diazo compds. of 2,4,6-trinitro-1-aminobenzene, its homologs, or its substitution derivs. are coupled with *N*-alkyl-, *N*-aralkyl-, or *N*-arylanilinesulfonic acids, their homologs, or their substitution products, giving dyes resistant to heat, acids and dil. alkalies and are especially suitable for acetate silk. Examples are given.

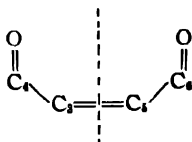

Azo dyes. I. G. FARBENIND. A.-G. Brit. 282,151, Sept. 14, 1926. The azo dyes obtained by coupling diazo compds. with dihydroxynaphthalenesulfonic acids are converted into new dyes by treating them with an aromatic sulfonyl halnide such as *p*-toluenesulfonyl chloride, in equimol. proportions, in the presence of an acid-binding substance such as Na_2CO_3 . Examples are given of dyes which dye wool in reddish shades fast to light and fulling.

Azo dyes. I. G. FARBENIND. A.-G. Brit. 282,682, Dec. 22, 1926. Azo dyes yielding violet shades are formed in substance, on a substratum, or on the fiber by coupling diazo compds. of monoaminocarbazoles such as diazotized 1-aminocarbazole with arylides of 2,3-hydroxynaphthoic acid such as the dianiside, naphthylamides, *p*-phenetide and *p*-aniside.

Monoazo dyes. I. G. FARBENIND. A.-G. Brit. 282,683, Dec. 23, 1926. Monoazo

dyes yielding blue and violet to black shades on wool and suitable also for dyeing "acetate silk" clear fast shades are made by coupling the diazo compds. from 4-nitroaniline-2-sulfonic acid or its substitution products, 5-nitro-2-aminobenzyl- ω -sulfonic acid or a sulfonic acid of 4-nitro-1-aminonaphthalene with 2-(4'-hydroxyphenyl)aminonaphthalene or its substitution products. Several examples are given.

Indigoid dyes. HERMANN STAUDINGER, RICHARD TOBLER, ROBERT STOCKER, JAKOB MÜLLER AND ARMIN BUCHER (to Soc. anon. pour l'ind. chim. à Bâle. U. S. 1,679,277, July 31. Unsymmetrical indigoid dyes are characterized by the symmetrical atom grouping:

the first member of which is attached by the carbon atom C_3 to the S atom of a thionaphthol nucleus and by the carbon atom C_4 to a β -C atom in α -position to this S atom, and the second member of which belongs to a five-membered heterocyclic complex contg. a S atom or an NH group and condensed with a benzene nucleus. These dyes form dark powders which dissolve in H_2SO_4 of 98% strength with violet-red to green and olive color, yielding with hyposulfite and caustic soda soln. yellow to olive-green vats which dye cotton fast brown to Bordeaux, violet, blue and gray tints. Numerous examples are given.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 633,958, May 5, 1927. Vat dyes which give violet colors on cotton and are resistant to soap and boiling with Na_2CO_3 are prepd. by condensing α -diamines with a perylenetetra-carboxylic acid contg. one to three halogen atoms. In an example dichloroperylene-tetra-carboxylic acid is condensed with α -phenylenediamine.

Vat dyes. I. G. FARBENIND. A.-G. Fr. 634,305, May 12, 1927. The derivs. of 2,3-naphthhisatin, which are substituted by halogen in the nucleus and in which the O of the keto group in the α -position is replaced by substituents easily replaced, are condensed with monoethers of 1,4-dihydroxynaphthalene or their derivs. in which the α -position to the OH group is free. Dyes are obtained which dye textiles green from the vat.

Vat dyes and intermediate products. I. G. FARBENIND. A.-G. Fr. 634,583, Dec. 21, 1926. The products which result from the action of alkylating agents, or of alkyl derivs. contg. two substituents capable of being exchanged, on pyrazolanthrone or its derivs. substituted in the nucleus are treated with alk. condensing agents to produce yellow to orange vat dyes. The alkylpyrazolanthrones may be prepd. by the action of alkyl ethers of toluenesulfonic acid or of H_2SO_4 .

Dye intermediates. BRITISH DYESTUFFS CORP., LTD., J. B. PAYMAN and H. WIGNALL. Brit. 281,795, Sept. 20, 1926. Sulfoamidoarylates of 2,3-hydroxynaphthoic acid are made by condensing the acid with aromatic sulfonamides contg. a primary or secondary NH_2 group as a substituent in addn. to the sulfonamide group, the H of which may also be substituted by a hydrocarbon radical. Aniline- m -sulfonamide, aniline- m -sulfonanilide, o -toluidine-4-sulfonamide, p -toluidine-3-sulfonanilide, methyl-aniline-4-sulfonamide, ethyl- o -toluidine-4-sulfonanilide and like compds. may be used and the production of some of these starting materials also is described.

Intermediate products for dyes. I. G. FARBENIND. A.-G. Fr. 634,199, Feb. 22, 1927. Diazosulfamic acids of the aromatic series are prepd. by treating disulfamic acids or aminoarylsulfonic acids in the cold with the quantity of nitrous acid necessary for the diazotization of one amino group. Several examples are given.

Chlorinated hydroaromatic compounds containing nitrogen. THEODORE VOLTZ (to The Firm Durand & Huguenin Soc. Anon.). U. S. 1,679,998, Aug. 7. By chlorinating the aromatic amines or their hydrochlorides in an indifferent medium such as $PhCl$ or C_6H_6 which does not allow hydrolysis, with exclusion of moisture, chlorinated products contg. N are obtained. If aniline is treated in $PhCl$ and heat is applied toward the end of the reaction while continuing the introduction of Cl, there is obtained the octachlorochloro-*ketiminohexahydrobenzene*, a "fairly cryst." substance, m. 151° . When the reaction between aniline and Cl is effected in C_6H_6 and the introduction of Cl is interrupted soon after soln. takes place, hexachlorochloro-*ketiminotetrahydrobenzene*, m. 125° , is obtained. These compds. are stable at ordinary temp. but when

heated to about 170° decompose with liberation of Cl. α -Naphthylamine yields pentachloro- α -chloroketimino-tetrahydronaphthalene, prismatic crystals, m. 122°. β -Naphthylamine gives the pentachloro- β -chloroketimino tetrahydronaphthalene, prisms, m. 118.5°. The aminoanthraquinones react similarly. Pentachloro- α -chloroketimino-tetrahydroanthraquinone forms bright yellow prisms, m. (decompn.) 190°; the corresponding β -deriv. forms rhombic leaves, m. 210°. Various details of procedure are given. The products obtained may be used as dye intermediates.

Fast dyes formed on the fiber. THEODOR KIRCHHEISEN and JOHANNES GÜRTLER (to Grasselli Dyestuff Corp.). U. S. 1,680,791, Aug. 14. In dyeing material such as cellulose acetate, pelts, hairs or feathers, a diazotizable amine, *e. g.*, aminoazobenzene or dichlorobenzidine, is diazotized on the fiber in the presence of Na 2-hydroxynaphthalene or other compd. to be coupled. Numerous examples are given.

Anthraquinone derivatives. I. G. FARBENIND. A.-G. Brit. 282,452, Dec. 20, 1926. The process described in Brit. 276,408 (C. A. 22, 2470) is applied also to the introduction of cyclic paraffin amine residues generally into the anthraquinone nucleus; *e. g.*, 1-amino-4-bromoanthraquinone-2-sulfonic acid is condensed with pentamethyleneamine or bornylamine in the presence of Na₂CO₃, CuSO₄ and aq. alc. The products dye wool from an acid bath blue shades fast to light.

Indanthrene. DONALD G. ROGERS (to National Aniline & Chemical Co.). U. S. 1,679,230, July 31. In making *N*-dihydro-1,2,1',2'-anthraquinoneazine by subjecting 2-aminoanthraquinone to fusion with KOH, the fused mass is dissolved in water and the alkali metal salt of the leuco dye is crystd. from the resulting soln.

Arylaminonaphthalene derivatives for use in dyeing. I. G. FARBENIND. A.-G. Brit. 282,111, Dec. 13, 1926. Arylaminonaphthalene derivs. are obtained by heating in an open vessel or in an autoclave, and in the presence of a bisulfite soln., an amino- or hydroxy-substituted naphthalene or a deriv. other than sulfonic or carboxylic acids of 1,8-diamino-, dihydroxy-, or aminohydroxy-naphthalene, with an aminobenzene deriv. contg. a further free or substituted amino group or a free or substituted OH group. The naphthalene derivs. which may be used include: α - and β -naphthol, α - and β -naphthylamine, 2,7- and 1,5-dihydroxynaphthalene; benzene derivs. which may be used include *o*-, *m*- and *p*-phenylenediamine, *o*-, *m*- and *p*-aminophenol, leucoindophenols, leucoindamines and sulfonic, carboxylic or other substitution products of these compds., 4,4'-aminohydroxydiphenylamine, 4,4'-diaminodiphenylamine-2-sulfonic acid. Instead of reagents contg. the amino group there may be used the corresponding NO₂ compds. with the addn. of formic acid as a reducing agent. The products may be used for producing dyeings fast to water on pelts, animal fibers in general, and "acetate silk" by after-treatment with oxidizing agents.

Sulfonation. HENRY B. FABER (to National Aniline & Chemical Co.). U. S. 1,679,211, July 31. "Spirit blue" or other alc.-sol. org. coloring matters are sulfonated in solid state with gaseous SO₃.

Dyeing artificial silk. I. G. FARBENIND. A.-G. Fr. 634,036, May 7, 1927. Azo dyes contg. a dihydroxydialkylamino group are used for dyeing acetate silk. Thus, 4-nitroanilineazodihydroxydiethylaniline gives a clear yellowish red, 3,4,5-trichloroanilineazodihydroxydiethylaniline a clear orange, 4-nitroanilineazodihydroxydiethyl-3-amino-1-methylbenzene a rich yellowish red and 2,4-dinitroanilineazodihydroxydiethyl-3-amino-1-methylbenzene a deep Bordeaux.

Dyeing cellulose esters and ethers. W. WHITEHEAD and C. DREYFUS (to British Celanese, Ltd.). Brit. 282,036, Dec. 11, 1926. Dyes such as 1,4-hydroxyamino-anthraquinone, 1-methylaminoanthraquinone and *p*-nitrobenzene-azodimethylaniline are applied as solns. in an org. solvent or solvent mixt. such as C₆H₆, toluene, xylene, ethylene dichloride, dichloroethylene, trichloroethylene, perchloroethylene, and MeOH, EtOH, PrOH, BuOH or AmOH.

Dyeing cellulose acetate. GEORGE H. ELLIS, HENRY C. OLPHIN and WILLIAM B. MILLER (to Celanese Corp. of America). U. S. 1,679,935, Aug. 7. Material comprising cellulose acetate is treated with 3,3'-dinitro-4,4'-diamino diphenyl or other suitable nitro deriv. of a compd. contg. at least 2 aryl radicals linked together by a linkage only partly comprising N. Numerous examples are given.

Dyeing "acetate silk" and similar materials. SOC. ANON. POUR L'IND. CHIM. A. BALZ. Brit. 281,704, Dec. 4, 1926. A dye of the general formula NH₂-R'-N:N-R''-NH₂, in which R' and R'' are the same or different aryl radicals of the benzene series, *e. g.*, the dye obtained by sapon. the product from diazotized *p*-aminoacetanilide and cresidine, is first applied and then diazotized on the fiber and coupled with 2,3-hydroxynaphthoic acid or β -naphthol in acid or neutral soln. The dye bath may contain a "distributing agent" such as delimed sulfite cellulose lye, condensation products of CH₃O

and naphthalenesulfonic acids, "sulfonation products of residues from org. chemical manufactures," humin substances or soap solns. Fast deep black or marine blue shades may be obtained depending on the proportion of the primary dye used.

Dyeing cellulosic fibers. HERMINGHAUS & Co., GRS. AND K. WENZ. Brit. 281,696, Dec. 1, 1926. The dyeing properties of cotton, artificial silk or other cellulosic material are altered by treatment with POCl_3 after a preliminary treatment with a dil. alkali soln. (suitably a 3% NaOH soln. in alc. for cotton or a 1.5% alc. NaOH soln. with artificial silk). The affinity of the material for substantive dyes is reduced and its affinity for basic dyes is increased.

Reserve dyeing on vegetable fibers. HANS LEEMANN and GIOVANNI TAGLIANI (to Munitex Corp.). U. S. 1,679,477, Aug. 7. Fiber, yarn or fabric of vegetable material is locally printed with an alkalinizing agent and then treated with a suitable esterifying aromatic acid chloride to alter the locally treated fiber and form a reserve effect; the material is then washed and the reserved parts and remaining fibers are subsequently successively dyed (cf. C. A. 22, 503). U. S. 1,679,478 specifies a similar process in which dyeing is effected by successive use of acid and substantive dyes. U. S. 1,679,479 specifies dyeing in a single bath contg. both substantive and acid dyes. U. S. 1,679,480 specifies dyeing by treating the material, after washing, with a salt of a diazotizable base and then diazotizing and treating with a developing substance. U. S. 1,679,481 specifies treating the locally altered fibers with a covering substance and then treating the material successively with basic and substantive dyes.

Apparatus for dyeing yarn on perforated metal bobbins. LOUIS BOUNOUS. U. S. 1,681,088, Aug. 14.

Absorbent textiles. ALBERT CHARBONNEAU. Fr. 633,719, Sept. 11, 1926. To render textiles such as linen absorbent, they are treated in alkali lye contg. milk of lime and $\text{Na}_2\text{S}_2\text{O}_4$ and then in an acid bath.

Sizing textiles. HENRY BERTRAND ET CIE. Fr. 634,560, Sept. 20, 1926. A sizing bath is made of gelatin, wax and linseed oil in suitable proportions, which is heated to 55° and the textile is dipped for about 15 min., dried in the cold, shaken and dried in a warm chamber.

Textile fiber from sugar cane. JOAQUIN J. DE LA ROZA, SR. (to Bagasse Products Corp.). U. S. 1,681,223, Aug. 21. Cane is subjected to fermentation by the action of enzymes naturally present to initiate generation of acids by the fermentation, and the fibrous portion of the cane is then retted with running water. Burned cane stalks may be utilized.

Apparatus for aging textile fabrics by steam treatment. J. S. WILSON, G. W. SHEARER, J. THOMAS and SCOTTISH DYES, LTD. Brit. 282,133, Sept. 9, 1926.

Impregnating fabrics. HERMAN E. BROWN and JORDAN H. STOVER (to Respro, Inc.). U. S. 1,680,497, Aug. 14. An unspun unwoven fabric is treated with rubber compn. or other suitable binding material in the form of a dough-like semi-solid plastic material having such high cohesiveness and adhesiveness as to be capable of penetrating around and between the natural fibers and the material is subjected to pressure to cause only partial filling of the interstices of the fiber by the binder. An app. is described.

Coating cloth with a cellulose derivative. CAMILLE DREYFUS. Fr. 634,345, May 13, 1927. A cellulose ester or ether is spread on a polished surface and dried and cloth wetted with a solvent for the ester or ether, is pressed on to the surface and dried, whereby a film of the cellulose deriv. is obtained on the cloth.

Apparatus for recovery of volatile solvents from coated fabrics. HERBERT S. THOMPSON. U. S. 1,678,886, July 31.

Wet-spinning of flax, hemp and like fibers. G. PETROV and N. ALEXEEV. Brit. 281,897, Feb. 1, 1927. In order to enable working of the fiber at lower than usual temps. or even without any heating it is treated with a substance selected from free sulfonic acids of aromatic compds. with and without hydrocarbon side chains, sulfonic acids of hydrogenated aromatic hydrocarbons or their derivs., naphthasulfonic acids, fatty-aromatic sulfonic acids, or sulfonic acids which are obtained by sulfonating aromatic, hydroaromatic or naphtha hydrocarbons in the presence of an alc. such as PrOH , BuOH or iso- Pr alc. or salts of such acids, which may be used instead of the substances specified in Brit. 251,590 (C. A. 21, 1362). Various sulfonated tars, hydrocarbons, glycerides or fatty acids and their emulsions and mixts. with other substances may be used.

Drying threads and cloth. ÉDOUARD JUSTIN-MUELLER. Fr. 634,079, May 9, 1927. An app. for drying threads and cloth comprises a roller suitably covered and an extensible endless band arranged so that the thread or cloth passes between them, a

suction being applied at the side of the band away from the thread in the neighborhood of the roller.

Treating artificial threads, films, etc. HENRY DREYFUS. Fr. 634,166, May 11, 1927. The physical properties of artificial threads, etc., are improved by submitting the threads to a weighting or charging process, such as treatment with tannic acid or SnCl_2 followed by a fixing agent such as a phosphate.

Treating artificial threads, films, etc. HENRY DREYFUS. Fr. 634,165, May 11, 1927. In weighting artificial threads, etc., of cellulose acetate or other deriv. of cellulose, the capacity to absorb the weighting agents is increased by treatment with a soln. which swells the cellulose deriv. such as an aq. soln. of lactic acid, alc., acetone, phenol or NH_4CNS . The weighting is accomplished in two steps, the application of an aq. soln. of a metal chloride or other salt followed or preceded by the application of a pptg. agent such as a phosphate, silicate, or tannic acid.

Artificial silk. BENNO BORZYKOWSKI. Fr. 634,045, May 9, 1927. Artificial silk produced in the centrifugal process is put on perforated tubes for washing, bleaching, etc.

Artificial silk cloth. BENNO BORZYKOWSKI. Fr. 634,043, May 9, 1927. Artificial silk from viscose alone or mixed with other fibers is made into cloth before desulfuration or bleaching.

Sizing artificial silk. GEBRÜDER SUCKER. Fr. 634,068, May 9, 1927. In a sizing machine for artificial silk, the thread passes over rollers mounted on springs to compensate for variations in tension on the thread.

"Linen appearance" on fabrics such as cotton. D. DEGONCZ and A. S. JONES (to Arnold Print Works). Brit. 282,002, Dec. 9, 1926. The fabric is impregnated with caustic alkali, dried, and then treated with cuprammonium soln. Cf. C. A. 22, 2472.

"Wooly appearance" on goods of vegetable fiber. EMIL GMINDER. U. S. 1,679,767, Aug. 7. Woven, knitted, or other fabrics of vegetable fiber are treated to produce a slight nap on the fabric and then treated with an alk. soln. such as a 15% Bé NaOH soln. to cause the nap to shrink or curl.

Forming yarn from asbestos pulp. JOHN A. HEANY (to World Bestos Corp.). U. S. 1,681,234, Aug. 21. Mech. features.

Degreasing wool. I. G. FARDENIND. A.-G. Brit. 282,164, Sept. 17, 1926. Raw wool is degreased by use of the Me, Et or other org. ester of carbonic acid, alone or mixed with other usual solvents. Residual solvent is removed by washing the wool with water, and may be recovered by extn. with $\text{C}_6\text{H}_6\text{Cl}_2$ and distn.

Washing clothes. H. VONTOBEL. Brit. 282,588, May 19, 1927. Clothes are "steeped" in a cold aq. soln. of Na_2CO_3 , soap, borax and Na perborate to which has been added enzymes such as peroxidase, oxidase, oxygenase, tyrosinase or catalase and catalytic agents such as FeSO_4 or CuSO_4 .

Laundry blueing composition. H. H. ROCKWEG. Brit. 281,998, Dec. 8, 1926. A compn. not affected by soap or by Cl is formed of ultramarine 75-150, NaHCO_3 1000-2500, and dragon's blood 3-15 parts, with or without soap 4000-7000 parts.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Modern paint mills. FRIEDRICH HUTH. *Farbe u. Lack* 1928, 339-40.—A new roll mill (Bandwalzenmühle) consists of 6 horizontal rolls planetarily surrounding a 7th. The rolls are hollow and the walls are slotted spirally. Each roll is in contact with the adjoining ones. The center roll rotates counter to the outer rolls. The machine occupies 16 sq. m. floor space and requires but one operator. The capacity is 900-1200 kg. pigment. G. G. SWARD

Rapid testing apparatus for paint. A. V. BLOM. *Chem. Fabr.* 1928, 102-3.—Two parallel chains are mounted on pairs of cog-wheels 2 m. apart so as to carry between them 50 test sheets 10×20 cm. The chains travel at 20 cm./min. and carry the sheets through 3 heating chambers and one freezing box. Sprays are fitted between the chambers, one of which can be filled with corrosive gases if desired. The strips are also submitted to the action of ultra-violet light and that from a "Sollux" lamp. A typical time of treatment is 5 days, and it is claimed that with this app. natural weathering conditions are closely imitated. B. C. A.

"Accelerated testing" of paints. K. WÜRTH. *Farben-Ztg.* 33, 1470(1928).—A brief account of the historical development of accelerated paint tests. B. C. A.

Acidproof paints. RUD. SCHWARZ. *Farbe u. Lack* 1928, 315, 325.—A review.

G. G. SWARD

Pigment and vehicle. E. KLUMPP. *Farben-Ztg.* 33, 1044-5(1928).—The absorption by white lead, ZnO, blanc fixe and china clay of various aq. and oily vehicles is tabulated, the value being expressed in terms of vol. The results are discussed with reference to the relation between adsorption and absorption. A white lead-linseed oil paste (67% of oil on pigment by vol.) consists of primary white lead particles sep'd. by a thin layer of oil, but a ZnO-paraffin oil paste (440% of oil on pigment by vol.) consists of agglomerates or secondary particles composed of wetted primary particles. Other factors possibly tending to raise the vehicle absorption of a pigment are the presence of adsorbed gases or vapors and the formation of "vehicle-sheaths" of relatively considerable diameter around the particles.

B. C. A.

Pigments. I. Basic carbonate and basic sulfate white lead. H. WOLFF. *Farben-Ztg.* 33, 1343-6(1928).—The chem. similarity of basic carbonate and basic sulfate white leads is reflected in parallelism in their properties. Comparisons of oil absorptions, drying times of paints contg. these pigments, mech. properties of films, resistance to weathering, etc., support this contention in general; exceptions are indicated in questions of opacity, retention of gloss, and tendency to support rusting (the greater tendency of the carbonate in this connection being tentatively attributed to CO₂ derived from the pigment rather than to impurities therein).

B. C. A.

Titanium oxide as a new white pigment. MARIO TALENTI. *Giorn. chim. ind. applicata* 10, 261-4(1928).—A description of the production, properties and uses of TiO₂, with particular reference to the process used at the plant of the Società Titanium at Bovisà (Milano), and with illustrations of the plant. The av. compn. of the product made at Bovisà is TiO₂ 98.4, ZnO 0.9, SiO₂, Fe, etc. 0.4 and H₂O 0.25% and its covering power is 4 times that of white lead.

C. C. DAVIS

Metallic lead in red lead. K. WÜRTH. *Farben-Ztg.* 33, 1473-4(1928).—Heinrich's work on the presence of metallic lead in red lead used in glass manuf. is discussed from the point of view of paint technology.

B. C. A.

Red lead problems. I. Settling and hardening of red lead. II. Color of red lead. III. Red lead as a composite pigment. C. P. VAN HOEK. *Farben-Ztg.* 33, 981-3, 1046-9(1928).—A review of the literature on the causes of settling and hardening of the sediment in red lead-oil paints, and their successful overcoming in modern "dispersed" red leads. Among the many influences discussed are grinding, presence or absence of turpentine or other diluent, formation of lead soaps and lead glyceroxide (an important factor in hardening), dependence of this factor on free monoxide content of the pigment and free fatty acid content of the oil, particle size, and rate of settling (a slow-settling red lead usually not hardening). A somewhat full reference to Junk's work indicates that the settling and hardening cannot be attributed to one particular cause, many varying factors being jointly responsible. Microscopical examn. reveals "active" and "inactive" particles, absence of the latter in "dispersed" red lead giving it its favorable non-settling properties. This activity or non-activity is accounted for by variations in the structure of the labile combination of lead monoxide and peroxide constituting the pigment. Suggestions that water is adsorbed on the surface of "dispersed" red lead are disproved. The variation in color of red lead is discussed with reference to the color of different varieties of lead monoxide and peroxide, the probable constitution of red lead being a lead monoxide substratum on which are adsorbed ultra-microscopic particles of PbO₂. Microscopical examn. shows that conversion of lead monoxide into red lead is not accompanied by any appreciable increase in particle size, the heterogeneous nature of the red lead particles being demonstrated under ordinary and polarized light. Various views on the composite nature of the pigment are discussed.

B. C. A.

Comparative examination of some lithopones. C. R. HALL. *Farbe u. Lack* 1928, 322-4.—A review of the recent improvements in lithopone. Photomicrographs under various conditions of some German and Dutch products are given.

G. G. SWARD

Oil absorption of highly dispersed red lead. SCHERTEL. *Farbe u. Lack* 1928, 314.—Polémique with F. Hülsenkamp (cf. C. A. 22, 3053). S. claims that H. has confused the ratio of the dry pigment with that of the prep'd. paint.

G. G. SWARD

Negative catalysis as a means of improving the drying of oils. A. EIBNER. *Farben-Ztg.* 33, 1222-4(1928).—A general discussion of the functions of neg. catalysts; with special reference to the effects of undercoats on coats subsequently applied and the neutralization of such effects by "flattening" the undercoats.

B. C. A.

Comparison between linseed oils from Palestine, Semirechie and Smolensk, and drying oils obtained from them. F. GOGOLEV. *Oil and Fat Industry* (Russia)

1928, No. 2, 46-8.—Characteristics of the 3 kinds of seeds are given and the following consts. for the oils from Palestine (1925), Palestine (1926), Semirechie, and Smolensk, resp.: Color faint, yellow, yellow, golden yellow; sp. gr. 0.936, 0.936, 0.933, 0.932; refraction 81.7, 82.2, 81, 84; acidity 2.4, 3.4, 2.9, 0.8; sapon. no. 196, 190.8, 189.6, 189; solidifying point 13.5°, 15.5°, 20°, 28°; I no. 173, 174.7, 165.7, 179; drying time in days 9, 12, 9, 10; O no. 14.4, 16.2, 15.6, 17.2. Drying oils prepd. from the Palestine (1926), the Semirechie and the Smolensk oils by adding 4% Pb Mn oleate and heating to 155°, had, resp.: Refraction 96.7, 93.6, 99.1; O no. 13.1, 12.5, 15.3; drying time 9 hrs. 30 min. to 15 hrs. 40 min., 6 hrs. 40 min. to 12 hrs. 10 min., 8 hrs. 20 min. to 14 hrs. The viscosities of the drying oils decreased with the increase of I no.

A. A. BOEHLINGK

Modern solvents for the varnish industry. A. BRESSER. *Notiz. chim.-ind.* 3, 280-5(1928).—Following a description of the development of this industry (cf. C. A. 22, 1485), the properties and uses of various individual solvents are reviewed, with quant. data in tabular form.

C. C. DAVIS

"Crystallizing" varnishes and "crackle" varnishes. F. KOLKE. *Farben-Ztg.* 33, 1281-3(1928).—The nature of "crystallizing" varnishes and "crackle" varnishes is indicated, the former depending on the drying peculiarities of tung oil and the microscopically wrinkled surface produced under specified conditions, while the latter (which are generally nitrocellulose lacquers) owe their characteristic behavior to low content of non-volatile matter, freedom from plasticizer, and contrast in elasticity with the undercoat. The undercoat is made necessary by the obviously poor adhesion of the "crackle" lacquer, and is preferably not dry when the latter is applied.

B. C. A.

Viscosity of nitrocellulose. H. DABISCH. *Farben-Ztg.* 33, 1105-6(1928).—The statement by Merz (C. A. 22, 2269) that the Engler viscometer gives "scientifically exact" measurements of the viscosity of nitrocellulose is criticized on the grounds that all nitrocellulose solns. are more or less plastic, but no distinction between plasticity and true viscosity is recorded in Engler detns. An ideal viscometer will work at sufficiently high pressure to render plasticity effect negligible. From consideration of the influence of various solvents and diluents on the viscosity of nitrocellulose, a mixt. of 45 pts. of abs. EtOH and 55 pts. of pure BuOAc is recommended as the most desirable solvent. The concn. of the soln. is adjusted for each type of nitrocellulose used so that normal lacquer consistency is obtained.

B. C. A.

Binding agent for colors, varnishes, etc. (Fr. pat. 634,275) 18. Electrolysis in the manufacture of white lead (PAMFILOV, IOFINOV) 4. Snow-white and bright-colored, non-poisonous, highly elastic rubber varnish with TiO₂ (DITMAR) 30.

MARGIVAL, F.: *Détrempe et badigeons*. Paris: Desforges, Girardot et Cie. 160 pp.; 15 francs. Reviewed in *Chimie et industrie* 19, 1182(1928).

Titanium pigment. LOUIS E. BARTON and LONNIE W. RYAN (to Titanium Pigment Co.). U. S. 1,680,316, Aug. 14. See Can. 274,070 (C. A. 21, 4079).

Product from drying oils. COMTAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 633,784, May 3, 1927. Drying oils, e. g., linseed oils, are heated beyond the point of becoming a jelly till they become liquid again. The product obtained can be dissolved in org. solvents, or mixed with resinous matters or can be hardened by heating in thin layers in the air.

Lacquers. W. SCHMIDDING. Brit. 282,574, Feb. 28, 1927. In the manuf. of lacquers as described in Brit. 247,599 (C. A. 21, 660), a special app. is used which is described in detail.

Polishing celluloid or enameled or lacquered surfaces, etc. M. B. MOORE. Brit. 281,751, Aug. 27, 1926. Various polishing compns. are specified comprising a mild volatile solvent of the base of the surface coating, e. g., a mixt. of "methylated spirits" and turpentine, a lubricant such as a mixt. of linseed oil, paraffin and Japanese wax or tallow, and sufficient of a polishing grit or abrasive to form a paste.

Polishing wax. JEAN MAS. Fr. 634,291, May 12, 1927. A polishing wax for floors is made by mixing and heating together, carnauba wax, ceresin, ozocerite, beeswax, oil of turpentine, mineral oil and a little alc.

Synthetic resins. BAKELITE GES. Brit. 282,414, Dec. 14, 1926. Phenol-aldehyde condensation products are rendered sol. or readily dispersible in oils by heating them with polyhydric or polycyclic phenols, such as naphthols, resorcinol, xanthine, dihydroxydibenzyl, diphenols, dicresols, dithymols, dicarvacrols and dinaphthols, or

mol. compds. of these phenols. The reaction may be assisted by catalysts such as substances like hydrated Mn oxide and Pb oxide which promote the formation or drying of varnish and the reaction mixt. may include oils such as linseed oil and mild oxidizing agents such as α - or β -nitronaphthalene or nitronaphthol; air or N oxides may be passed through the mass. The products are suitable for use in varnishes or paints mixed with other usual ingredients of such compns.

Synthetic resin. ARTHUR L. BROWN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,680,408, Aug. 14. A condensation product is formed by reaction of a phenol, China wood oil and CH_2O or other substance contg. an active CH_2 group. The product is suitable for *elec. insulation*.

Synthetic resin. GUSTAVE E. LANDT (to Diamond State Fibre Co.). U. S. 1,679,312, July 31. Substantially pure xylenol is caused to react with CH_2O to form an initial condensation product which by further heating may be converted into a hard, infusible and insol. product.

Synthetic resin. JAMES MCINTOSH (to Diamond State Fibre Co.). U. S. 1,679,322, July 31. A phenolic compd. such as PhOH is caused to react with an essential oil having an aldehyde base, *e. g.*, with oil of cassia, to form a fusible, sol., non-cryst. condensation product which by further heating can be transformed into a hard, infusible product. Cf. *C. A.* 21, 3756.

Synthetic resins. SELDEN CO. Brit. 281,742, July 7, 1926. A resinous substance capable of being hardened by heat, such as a glycerol phthalate resin, is admixed with a liquid, high-b. p., non-resinifiable ester of an aromatic polybasic acid, such as di-Et phthalate, before hardening. Natural resins such as shellac also may be used.

Synthetic resins. F. VACHER (to Soc. anon. la fibre Diamond). Brit. 282,435, Dec. 16, 1926. Condensation products which may be rendered insol. and infusible by further heating are obtained by condensing an aldehyde with an amine and heating the product under reduced pressure. Either aliphatic or aromatic aldehydes and amines may be used and the condensation may be assisted by catalysts such as acids, bases or salts, or, preferably, phenols. An example is given of the condensation of PhNH_2 and CH_2O with or without cresol.

Resinous products by polymerization. WESLEY R. GERGES (to The Barrett Co.). U. S. 1,679,214, July 31. Material such as solvent naphtha contg. polymerizable constituents of the coumarone and indene classes is subjected to a polymerizing action, *e. g.*, by use of H_2SO_4 , and before the polymerization is complete it is arrested by the addn. of a non-neutralizing diluent such as water. The product is of lighter color than products made without the use of the diluent.

Urea-formaldehyde resins. ALPHONSE GAMS and GUSTAV WIDMER (to Soc. anon. pour l'ind. chim. à Bâle). U. S. 1,679,246, July 31. Insol. urea CH_2O condensation products are converted into sol. form by heating under pressure with aq. CH_2O .

Purifying phenol aldehyde resins. FRITZ SEEBACH (to Bakelite G. m. b. H.). U. S. 1,681,368, Aug. 21. In order to obtain alkali-sol. phenol-aldehyde resins free of acids, the resins are dissolved in alkalies such as NaOH solu. and there is added to the solns. Na soaps or other hydrotropic salts which have the property of rendering difficultly sol. or insol. substances sol. in water but do not affect the soly. of the phenol resin, and the resins are pptd. with CO_2 or other acid in the presence of the added hydrotropic salt or salts. U. S. 1,681,369 specifies treating fusible sol. phenol aldehyde resins with not more than an equal quantity of water and with sufficient alkali such as NaOH to form a colloidal suspension and then pptg. the resins by adding salts such as NaCl which have the property of salting out the resins.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

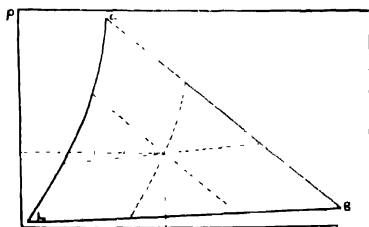

The fatty acids of seed oils of Brassica species. The composition of rape, ravisson, and mustard seed oils. T. P. HILDITCH, T. RILEY and N. L. VIDYARTI. Liverpool Univ. *J. Soc. Chem. Ind.* 46, 457-62T(1927).—The compn. of the fatty acids combined with glycerol in the fats of 4 representative oils of the genus *Brassica* has been detd. by quant. fractional distn. of their Me esters after preliminary sepn. of the mixed fatty acids by means of the varying solubilities of the Pb salts in alc. and Et_2O . The following gives the % of combined fatty acids in different oils: English rape seed (*Brassica campestris*), palmitic 1, lignoceric 1, oleic 32, linoleic 16, linolenic 1, erucic 50, Danubian ravisson (*B. campestris* var.), palmitic 2, behenic trace, lignoceric 2, oleic 20.5, linoleic 25.5, linolenic 2, erucic 47; English black mustard (*B. Sinapis nigra*), palmitic 2,

stearic trace, arachidic trace, lignoceric 2, oleic 24.5, linoleic 19.5, linolenic 2, erucic 50; English white mustard (*B. Sinapis alba*), palmitic 2, stearic trace, arachidic 1, lignoceric 1, oleic 28, linoleic 14.5, linolenic 1, erucic 50%. The total proportion of unsatd. fatty acids with 18 C atoms is fairly const. and approximates 45 to 47%.

T. S. CARSWELL

Approximate determination of butter and coconut fat in fat mixtures. THURE SUNDBERG. *Svensk Kem. Tids.* 40, 9-21(1928).

—From the accompanying graph the 70 butter fat, coconut fat and lard may be found when the Reichert-Meissl no. (RM) and Polenske no. (P) have been obtained. The point C is 100% coconut fat, P 16, RM 7.6; B is 100% butter fat, P 1.8, RM 27.7; and L is 100% lard, P 0.4, RM 0.5. The lines C-B and L-B are straight and C-L is slightly curved towards B. One % intervals are represented on the triangle by cross lines. The broken lines in the figure illustrate the lines involved in the coordinate-trilinear systems when the fat mixt. consists of equal parts of lard, coconut fat and butter fat. The graph is based on the consts. of 70 fat mixts. and results with it agree closely with established procedures.

Paul Jaeger's flow method for differentiating oils. HANS VON NABELL. *Chem Umschau Fette, Oele, Wachse u. Harze* 35, 121-3(1928).—N. shows 24 illustrations of patterns, obtained when various oils are dropped on Jaeger's specially prepd. carton-paper, representing drying oils, blubber, oleins of different origins and vaseline. N. considers Jaeger's method (Fließverfahren zur Unterscheidung pflanzlicher Oele. Stuttgart 1927, Verlag des Forschungs- und Lehrinstituts für Anstreichtechnik G. m. b. H.) a useful adjunct in analysis.

A. R. ROSE

Paul Jaeger's flow method for differentiating oils. JOHANNES SCHEIDER. Leipzig Univ. *Chem. Umschau Fette, Oele, Wachse u. Harze* 35, 123-5(1928).—Jaeger's method of differentiating wood oil from linseed oil is restricted to crude oil and is based on the formation of air bubbles along the fibers of the carton paper; wood oil dries with a wrinkled surface while linseed oil will fill the capillaries of the paper fibers and subsequent wetting of the spots brings out the difference in appearance. Only 3 types of patterns can form in Jaeger's method; the long time required for a test (7 days and more) will make its general adoption doubtful.

P. ESCHER

Hydrogenation of polymerized and oxidized oils. Z. TALANZEV (N. NOVGOROD). *Oil and Fat Ind. (Russia)* 1927, No. 8, 20-1.—Linseed oil previously polymerized by heating up to 300° was hydrogenated at 260°. A white and solid hydrogenated oil was obtained of superior quality with a titer of 63° and I no. = 12. T. suggests heating the oils before polymerization as less H₂ is required and the hydrogenated product obtained is of a different chem. structure and much higher in quality. Evidently no catalysts are required for a polymerization. G. BRAKHAMAN-DAM'VE. *Ibid* 22-3.—

A. A. BOEHLINGK

Action of air on the nickel catalyst prepared for oil hydrogenation. A. BAG. *Masloboino-Zhirovoye Delo.* No. 5, 6(1928).—Two samples of a Ni catalyst prepd. in the usual way and cooled in an atm. of CO₂ gas were used for the following expt. • The first sample was left exposed to the air for 1 month, and 0.34% mixed with 99.66% of cottonseed oil. The second sample was mixed with the same oil in the same proportion immediately after the Ni catalyst was prepd. The table shows the action of both catalysts.

Time of hydrogenation	Temp. of hydrogenation	Iodine no. Sample No. 1	Sample No
1 hour	240°	79.3	75.6
2 hours	240°	59.4	47.6
2 1/2 hours	240°	47.4	36.8

Because of the treatment of the Ni catalyst with CO₂ its deterioration can be considered negligible.

A. A. BOEHLINGK

The utilization of coconuts. E. SCHMÜLLING. *Z. Ver. deut. Ing.* 72, 989-91 (1928).—In 1927 more than 1.5 million tons of copra were produced, with a value of about 900 million marks. For each ton of copra at least 5000 coconuts are needed. From copra an edible oil, about 65% of the wt. of the copra, is prepd. When 5%

H₂O remains in the copra the material is quite stable, but when more than this quantity is present, it spoils rapidly, its fats undergoing hydrolysis. The profit from coconuts is small; by utilizing the fiber also additional income can be had. Biologists and chemists had always said that only ripe nuts would make good copra, and only unripe nuts good fiber. B. G. H. van der Jagt, an engineer, found that if the ripe nuts were softened by treatment with NaOH soln., with heating, and the fiber flattened by pressure or rolling, it was possible to prepare a good quality of yarn. A new industry has developed accordingly. Machines for making yarn and copra have been perfected, and now coconuts are worked up on a factory scale, with yarn, copra and fuel (from waste) as the products. At present efforts are being made to prepare finer yarn than Nos. 1 and 2, and to utilize the parts of the coconut now burned, as in making artificial wood.

W. C. EBAUGH

Cottonseed and its by-products. W. L. DAVIES. *Fertilizer Feeding Stuffs and Farm Supplies J.* 13, 451-2(1928).—A brief discussion of the manuf. and compn. of cottonseed products.

K. D. JACOB

The fluorescence of Italian olive oils in Wood light. R. STRATTA and A. MANGINI. *Reale Scuola Ingegneria Torino. Giorn. chim. ind. applicata* 10, 205-7(1928).—When the surface of virgin-pressed olive oil was exposed to Wood radiation, a fluorescence varying from yellow to dark lemon-yellow was obtained. On exposure for at least 0.5 hr., this fluorescence changed to a natural sienna color. Olive oil extd. by solvents and refined gave a brilliant sky-blue fluorescence which did not change on prolonged exposure. Lower grade refined oils gave a blue-gray fluorescence. Virgin olive oils to which had been added refined lower grade oil or oil extd. by solvents changed their fluorescent colors as soon as 1% had been added. With 10% addn. the fluorescence became almost white, with 30% it became light blue, and from 60 to 100% the fluorescence became brilliant sky-blue, i. e., the color of the refined oil. By examn. of olive oil in Wood light, either by eye alone or with the aid of a colorimeter which is described, it is possible to ascertain whether a shipment of oil is identical with a sample. The spectrum of the fluorescence of a crude olive oil, particularly of a virgin oil, has a sharp red characteristic band which lies at 669 μ and is the same for all oils. This band allows the identification of a virgin oil even when 90% refined oil is present. This red band was absent in all refined oils. The intensity of the red band indicates the concn. of the virgin oil in a mixt.

C. C. DAVIS

Investigation of a distillate of tallöl. K. FRICKE. *Allgem. Öl- u. Fettztg.* 24, 45-6; *Chem. Zentr.* 1927, I, 1907.—The distillate was clear and oily. The unsapon. material (10.27%, Spitz-Hönig) was yellowish, with a green fluorescence and had a pleasant resinous odor. Treated with H₂SO₄ (1.53) and Ac₂O, it turns red, then brown. The fatty acids pptd. from the soap soln. show a sapon. no. 188.6 and an I no. (Wijs) 147.5. The esterification (Wolff) showed 28.44% of resinous acids, whose MeOH soln. gave crystals m. 138-40°, sapon. no. 181.3, I no. 162.2. The Storch-Morawski test gave an intense blue color, gradually turning green. A comparison with pure abietic acid shows that the present acid is a new compd.; its formula is C₂₀H₃₀O₂ and it is named "tallic acid."

A. L. HENNE

Application of castor oil in the manufacture of curd soap. V. SKVORZOV. Moscow Techn. School for Fat Industry. *Oil and Fat Industry (Russia)* 1928, No. 3, 15-17.—The following proportions were used for making soap with castor oil: 66% sunflower oil, 31% mixt. of sunflower and castor oil (castor oil being in the proportions of 5 to 15% to sunflower oil), 3% rosin. Five batches contg. 5, 7.5, 10, 12.5 and 15% castor oil, resp., produced soaps of the following compns.: total fatty acids 62.15, 62.77, 63.41, 63.92, 63.17%; unsaponified matter, 0.51, 0.68, 0.73, 0.77, 0.81%; free NaOH 0.080, 0.024, 0.063, 0.08, 0.08%. The cooking took 8 hours, settling 40 hrs. The data on castor-oil soaps supplied by G. Heffer and Ubbelode are not quite accurate. By using the above mixts. there is obtained a soap of high quality, in normal yield, and of normal water content. The cake is very hard. It lathers abundantly even with cold water. The soap does not soften in use. If more than 15% of castor oil is used the good qualities of soap disappear gradually.

A. A. BORHTLINGK

Washing sulfonated oils with salt solutions. C. RIESS. *Collegium* 1928, 298-301.—If a sulfonated oil is washed with NaCl or Na₂SO₄ soln. to remove free H₂SO₄, the Na salt of the sulfonated oil is formed and HCl or H₂SO₄ is set free. The reaction goes to completion. The titration curve of a sulfonated oil shows two breaks, one at pH 7.5, the methyl orange end point, caused by neutralization of the sulfo groups and the second at pH 10, the phenolphthalein end point, caused by neutralization of COOH groups.

I. D. CLARKE

Soap for the silk dyer. FRED GROVE-PALMER. *Am. Dyestuff Rept.* 17, 493-5

(1928).—A suitable soap should contain fat anhydrides 65% or more, combined alkali 8, free alkali less than 0.3, water 23. The low content of free alkali is important. A green olive oil soap gave good results. Failure to rinse out all of the soap is a frequent cause of trouble.

Wetting and emulsifying agents. AUGUST NOLL. *Papier-Fabr.* 26, 318-26 (1928); cf. C. A. 22, 710.—The chem. nature and physical properties of 16 more trade-named emulsants and 5 salts of tetrahydronaphthalene- β -sulfonic acid are reported, special attention being given to the emulsifying power. These wetting and emulsifying agents are rapidly increasing in importance and popularity. They all contain high-molecular alkali sulfonates, which have the great advantage over ordinary soaps of being unaffected by hard water or acid.

L. W. RIGGS

R. H. DOUGHTY

Discussion of soap in its relation to the scouring of wool (PROCTOR & GAMBLE) 25. Fuller's earth from New Zealand (ANON.) 18. *Sclerocarya caffra* [for use in soap manufacture] (BRANDWIJK) 17. The seeds of *Nerium oleander* L. (MATTHES, SCHÜTZ) 11D. Filter for oil (U. S. pat. 1,680,029) 1.

JAEGER, PAUL: Prüfung und Unterscheidung pflanzlicher Öle durch das neue Fließverfahren. Stuttgart: Forschungs- und Lehrinstitut für Anstrichtechnik. 26 pp. M. 1.60.

Stabilizing oils, fats and waxes by addition of a small proportion of furfural. JOHN Y. HUBER, JR. U. S. 1,680,047, Aug. 7.

Purifying palm oil or similar oils. AMERICAN SHEET & TIN PLATE CO. Brit. 282,321, Sept. 13, 1926. In connection with processes such as removal, purification and recovery of oil from tin plate, the oil is sepd. from an emulsion of oil and water and purified and dried by heating sufficiently to vaporize and expel substantially all the water. The emulsion obtained by scouring the oily metal plates may be broken by use of H_2SO_4 and steam or by use of niter cake, waste pickle liquor, lime, $CaCl_2$, $FeSO_4$, or Na_2SO_4 or alum. An app. is described.

Washing or extracting seed or oil cakes or other materials. E. SILVANO and V. L. CERRI. Brit. 282,446, Dec. 17, 1926. The material is treated in a thin layer on a conveyor belt or the like which acts as a filter for the treating liquid or ext. after it has passed through the layer. An app. is described.

Extraction of fatty materials. ADOLPHE PANSKY. Fr. 634,595, May 18, 1927. Fatty materials are extd. from animal and vegetable products by a solvent in known manner but under reduced pressure at a low temp.

Extracting fat from cacao beans. IVAN S. HOCKER (to The Hocker Corp.). U. S. 1,680,943, Aug. 14. Finely divided cacao beans are heated with water to dissolve water-sol. constituents and gelatinize the starch; the mixt. is then treated with a diastatic enzyme such as malt ext. at a temp. at which the starch is saccharified, and an agent such as yeast capable of inducing alc. fermentation is then added after a lowering of the temp. to a point suitable for the alc. enzyme; gases are thus produced which cause coalescence of the fat globules in the emulsion and carry them to the surface of the mixt., whence they are removed.

Apparatus for extracting grease from bones, hide trimmings or other materials by use of solvents. FREDERICK E. LYNN. U. S. 1,679,728, Aug. 7.

Fatty acids and their salts from oils and fats. G. PETROFF. Brit. 281,896, Feb. 1, 1927. Drying or semi-drying fats and oils such as linseed, sunflower, fish or castor oils are mixed with aromatic hydrocarbons or phenols or hydrogenated hydrocarbons or phenols, not exceeding 15%, and the mixt. is treated with not over 15% of concd. H_2SO_4 . When reduction of the I value and hydrolysis of the acid have been effected, the excess hydrocarbons are distd. off and the neutral glycerides obtained are split by use of sulfo-fatty acids of high mol. wt. Partial polymerization of the unsatd. fatty acids may take place.

Sulfonating fats, etc. H. FLESCH. Brit. 282,626, Dec. 23, 1926. Olive oil, ricinoleic acid, olein, castor oil or other materials are sulfonated by SO_3 or chlorosulfonic acid in the presence of glacial HOAc, formic, propionic, butyric, lactic or similar acids or the anhydrides of chlorides of the lower aliphatic acids. Mention is made of the sulfonation of linseed oil, fish oil or rosin oil by SO_3 in the presence of glacial HOAc.

Insoluble soaps from partial oxidation products of mineral oils. JOSEPH H. JAMES (to Clarence P. Byrnes, trustee). U. S. 1,681,237, Aug. 21. A product formed by catalytic partial oxidation of hydrocarbon vapors, or other similar partial oxidation product contg. aldehyde fatty acids, is treated with $Al(OH)_3$ or $Pb(OH)_2$ or otherwise

suitably treated to sep. the aldehyde fatty acids from other assocd. constituents and convert these acids into insol. soaps.

Substitute for black soap. JEAN-ULRIC MAROGER. Fr. 634,409, Sept. 15, 1926. Soap is mixed with a special earth found in the Gard department and known as "Sommières cleaning earth" in the proportion of 1 part of soap to 3 of earth.

28—SUGAR, STARCH AND GUMS

F. W. ZERBAN

Seedling propagation and selection. A. J. MANGELSDORF AND C. G. LENNOX. *Proc. Hawaiian Sugar Planters' Assoc.*, 47th Ann. Meeting 1927, 160-9(1928).—Male sugar-cane tassels shed their pollen normally when placed in H_2SO_4 soln. and female tassels live long enough to mature viable seed when kept in the same medium. This is a discovery of tremendous importance for crossing work, because it makes possible the complete isolation, from other canes, of the tassels used in crossing and permits of a certainty of parentage in breeding work that otherwise could be obtained only at a great expense. The Yellow Tip variety of cane lost 58.8% of its recoverable sucrose when allowed to lie in the field for 7 days after cutting, while the Badila variety lost only 16.2% in the same time. C_2H_4 did not have any effect in converting glucose into sucrose in cane during storage, but it did have a positive effect on germination of cane seed. Hard body seed stored for several days in a chamber contg. 0.01% C_2H_4 showed a marked increase in germination. K. D. JACOB

Preservation of cane seed and other experiments. R. E. DOTY. *Proc. Hawaiian Sugar Planters' Assoc.*, 47th Ann. Meeting 1927, 179-80(1928).—The factors involved in the CO_2 - $CaCl_2$ method of preserving sugar-cane seed were studied. The best procedure is to use air-dried seeds and seal them in air-tight cans in an atm. of CO_2 with $CaCl_2$ at the rate of 8.9 g. per 1000 cc. of gas space, and to store at 31°F. Excessive quantities of $CaCl_2$ should be avoided. Germination of seed cane was almost completely prevented in 30 days by planting the stalks in a bed of green cane leaves. Planting in dry cane leaves resulted in 13-17% germination, while 23-27% germination was obtained in rotted cane trash. Germination in normal soil was 41%. K. D. JACOB

Statistics of the distribution and yield of cane varieties in the season of 1927 (Java). W. J. HEYLIERS. *Arch. Suikerind.* 36, III; *Mededeel. Proefstat. Java-Suikerind.* 443-534(1928); cf. C. A. 21, 3478.—Statistics are given of the area and production of the varieties for 177 mills, representing 93.8% of the total area planted, in 4 tables as before. The area in EK 28 has been further reduced to 35.25% (sugar yield 13.4 metric tons per hectare). DI 52 has also lost ground (26.25%; 13.4 tons). No. 247 B, EK 2, SW 3, 90 F and EK madoc have become unimportant. But the area planted to POJ 2878 has expanded to 12.25% (15.7 tons sugar), and other POJ varieties to 10.5% (11.1-13.8 tons). P. R. PEKELHARING

Sugar cane variety tests in Louisiana during the crop year 1926-7. R. D. RANDS, SIDNEY F. SHERWOOD AND F. D. STEVENS. U. S. Dept. Agr., *Circ.* 36, 1-14(1928).—Analyses of 36 seedling mosaic-resistant varieties of sugar cane gave juice varying from 10.6° to 18.5° Brix with purity (sucrose) values from 53 to 87.2%. The mill used expressed about 61% of the total juice. Several promising new varieties are recommended for La. C. R. FELLERS

Sugar-cane mills and small power crushers in the Bombay Presidency. P. C. PATIL. Dept. Agr. Bombay, *Bull.* 139, 19 pp.(1927).—A considerable portion of the crude sugar produced in India is made on the native farms. Iron crushing mills and modern equipment are gradually replacing the old wooden mills which are operated by bullock power. K. D. JACOB

Sugar technology. W. R. MCALLEP. *Proc. Hawaiian Sugar Planters' Assoc.*, 47th Ann. Meeting 1927, 121-34(1928); cf. C. A. 21, 3477.—Exptl. results with the Oliver filter for juice settlings are tabulated. By acidifying the settlings to p_H 5.8-6.0 with HCl and then liming to p_H 7.3 the filtration rate of the settlings was improved to practically the same degree as with the Borden process, but filtering difficulties and contamination of the juice with $CaCl_2$ more than offset the low cost of the treatment. The effect of the addn. of varying quantities of inorg. salts, known to be present in settlings, on the filterability of cane juice was studied. $FeCl_3$, $AlCl_3$, $MgCl_2$, and the Na phosphates and aluminates had little effect. By acidifying Na_2SiO_3 to about p_H 7.5 and then adding it to settlings low in SiO_2 , at p_H 7.0-8.0, filtration was almost entirely stopped, although the total SiO_2 present did not exceed the amt. frequently occurring

naturally. When acidified Na_2SiO_3 was added to clarified juice a very voluminous and very slimy gelatinous ppt. was formed, which after drying contained 92% SiO_2 and 1.3% CaO . When this gelatinous ppt. was treated with H_3PO_4 it slowly dissolved until at p_H 6.8, which is the end point of the Borden process, it was no longer visible. The changes undergone by SiO_2 during the processing of cane juice are being investigated further. From a study of the compn. of press cakes from a no. of factories it was established that the ratio of fiber to SiO_2 in the cake solids is an indication of the cake-forming properties of the settlings. When this ratio decreases below 3.0 difficulties are experienced in filter press operation, requiring some special treatment of the settlings, but with greater ratios filtration usually proceeds without particular difficulty. A study of the *invertase method for detn. of sucrose* showed that it gives values lower than the regular acid hydrolysis method, by from 0.15 to 0.20% of the total sucrose. Red colors are the most desirable for p_H detns. on sugar-factory products, chlorophenol red being the most satisfactory in this respect. After liming, whether or not the juice has been heated, changes in p_H occur when the juice seps. into clear and muddy fractions. The mud is usually higher and the clear juice lower in p_H than the original mixt., but changes sometime occur in the opposite direction. Remixing the clear juice and settlings restores the original p_H except for the development of such acidity as may take place during the time required for manipulation. *Viscosities of molasses* produced at different factories ranged from 200 to 2000 poises. The relation of molasses viscosity to grain characteristics of the sugar is being studied by photomicrographic methods. *Colloidal material in com. sugar*.—The substance remaining in permanent suspension at p_H 6.3 coagulating and settling out below, and imparting an intense brown color to solns. above this p_H , has the ultimate compn. of $\text{C}_{20}\text{H}_{26}\text{O}_8$ and a mol. wt. of 404. This compd., originally sepd. from com. sugar may also be obtained by digesting bagasse as it comes from the mill with solns. of p_H 8.0. The material remaining in permanent suspension at p_H 7.6, sepg. out above, and imparting an intense brown color to the soln. below this p_H is in reality 2 substances. The compn. of one is a multiple, probably a rather large multiple, of $\text{C}_2\text{H}_2\text{O}_2$; the other is $\text{C}_2\text{H}_2\text{O}_4$. The first of these 2 compds. was also obtained by digesting bagasse in a moderately alk. soln.

K. D. JACOB

Report of the raw sugar technical committee. S. S. PECK, *et al.* *Proc. Hawaiian Sugar Planters' Assoc.*, 47th Ann. Meeting 1927, 23-36 (1928); cf. *C. A.* 21, 3477.—Of the total shipments of sugar received at the Crockett refinery during the first 8 months of 1927, 1.15, 0.36 and 0.96% was classed as sour, caked and sticky sugar, resp. The av. filtration rate was 79.3 and the polarization 97.62. The figures for caked and sticky sugar do not include sugar discharged from boiler hatches. *Caked sugar* results from storage too near boiler bulkheads during shipment and to stacking the bags while the sugar is still hot. Severe drying of sugar contg. excessive moisture also results in caking. Reduction of the alky. to the point where the sugar becomes slightly acid increases the tendency of the refined product to cake, while screening out the fine crystals greatly reduces caking. The term "caked" is applied to sugar solidified into a rigid mass which does not disintegrate to any great extent during the somewhat rough handling between the ship and the cut-in station. Caked sugar is a serious problem at the refinery because of the extra labor required, losses through damaged bags, damage to grain in grinding up the lumps, and a less satisfactory sepn. of the mass into individual crystals in the mixt. prepd. for affination. If the mass is at all plastic but still in such condition that it can only be removed from the bag with considerable difficulty, the sugar is designated as "sticky". The cause of *sticky sugar* is not definitely known but factories shipping caked sugar also produce sticky sugar, the latter usually in larger amts. In many cases stickiness seems to be caused by drying out that has not proceeded far enough to cement the sugar into a rigid mass. *Contamination of refined sugar with specks due to sulfate scale* can be greatly reduced by frequent and thorough cleaning of heating surfaces. A very small difference in the size of the sugar grains has a very great effect on refining characteristics. As the proportion of fine grains increases the efficiency of sepn. of the crystals and liquor in the centrifugals decreases very rapidly and the efficiency of sepn. of sucrose from impurities decreases greatly. *Dark crystals* are due to the inclusion of solid particles and microorganisms in the grain. The solids vary in size from particles too small to be resolved clearly under the microscope to particles of plant material of sufficient size to be easily identified. The greater part of the microorganisms consists of yeast and spores of fungi. The dark grains are objectionable in refining because of the effect of the fine matter in retarding filtration, rather than because of the introduction of coloring matter. There is considerable evidence to indicate that atm. conditions during storage and the length of time

of storage are important factors in the production of caked and sticky sugars.

K. D. JACOB

Examination of sugar-cane juice for p_H values after various treatments. T. LAKSHMANA RAO AND G. GANAPATI AYYAR. Madras Agr. Dept., *Yearbook 1926*, 73-9(1927).—The effect of boiling, centrifuging, addn. of kieselguhr and of filtering through paper on the p_H of cane juices was detd. by colorimetric and electrometric methods. There was no appreciable difference in the p_H values of juices from the same varieties of cane when treated by the various procedures. The p_H values of juices from different varieties of cane varied from 5 to 5.89. Colorimetric detns. with bromocresol purple gave p_H values which were very close to those detd. electrometrically. Methyl red gave much lower values.

K. D. JACOB

Preliminary boiler tests with preheated air at the sugar mill Wonoaseh (Java). I. HES AND H. J. SPOELSTRA. *Arch. Suikerind.* 36, III; *Mededeel. Proefstat. Java-Suikerind.* 535-62(1928).—The object of these tests was improvement in boiler efficiency, and reduction in cost of upkeep of furnaces and boilers, and of labor. On account of local conditions the preheater was placed in the first flue, and therefore it was not possible to investigate the attainable cooling down of the flue gases and the increase in efficiency resulting from it. But all tests showed an increase in efficiency of the boiler plant, without any operating difficulty.

P. R. PEKELHARING

Nature of the acidic substance formed on hydrolysis of acacia. LEONARD H. CRETCHER AND C. L. BUTLER. *Science* 68, 116-7(1928).—Gum arabic hydrolyzed with dil. H_2SO_4 yields an aldobionic acid of the formula $C_{12}H_{10}O_{12}$, which gives a strong naphthoresorcinol test (cf. Tollens, *C. A.* 2, 2693) and reduces Fehling soln. vigorously. On boiling with 12% HCl, the correct amt. of CO_2 is liberated and the glucose value calcd. from the amt. of I consumed in oxidation, as well as the percentage of Ca in the Ca salt, corresponds to the requirements of $C_{12}H_{10}O_{12}$ contg. 1 aldehyde and 1 carboxyl group.

L. W. RIGGS

The organization and cost of gul (crude sugar) making in the Deccan sugar cane tracts. P. C. PATIL. Dept. Agr., Bombay. *Bull.* 147, 18 pp.(1927).—In the small-scale operations common in India, the av. production of crude sugar is 60-65 lb. per man employed in crushing the cane, and evapg the juice, on the basis of a 12-hr. day. Production costs vary considerably in the different districts.

K. D. JACOB

Furnaces for making gul or crude sugar in the Bombay Presidency. P. C. PATIL. Dept. Agr. Bombay, *Bull.* 144, 35 pp.(1928).—The various types of native furnaces for the evapn. of sugar-cane juice are described and their merits discussed. Double, triple and multiple furnaces designed with special reference to efficient utilization of heat, are described and illustrated.

K. D. JACOB

Percentages of moisture and soluble matter in starches used by North Carolina mills. A. H. GRIMSHAW. N. C. State College Textile School. *Textile World* 74, 184-7(1928).—The results of tests are reported for moisture and soly. of the mill starches previously examd. microscopically (cf. *C. A.* 22, 2853). Of the 63 samples submitted by the N. C. mills, the majority were corn starch, but a few samples of potato and wheat starch were included. The methods used in this study as well as those of several manufacturers are described.

RUBY K. WORNER

Tests on ash, grit, color, pasting points and lasting qualities of starch. A. H. GRIMSHAW. N. C. State College Textile School. *Textile World* 74, 696-9(1928); cf. preceding abstract.—A report of further tests on starches submitted by the N. C. mills. The methods of analysis used as well as those of several manufacturers are described.

RUBY K. WORNER

A new soluble starch and an improved polarimetric Lintner method. H. C. GORE. Fleishmann Labs. *Ind. Eng. Chem.* 20, 865-6(1928).—Potato starch is mixed with 1.5 parts of 13% HCl, allowed to stand 6 days, thoroughly washed, and dried in warm air. The resulting product is used in an improved Lintner method for detn. of diastatic power.

T. S. CARSWELL

Entomology [in relation to sugar-cane soils] (SWEZEY) 15. Report of the work done by the agricultural chemist, Bengal, for the year 1926-27 (CARBERRY) 15. Report on agriculture (VERRET) 15. Pathology (LEE) 15. Mathematical interpretation of experimental results obtained with fertilizers for sugar cane (KUTSUNAI) 15. Chemistry [sugar cane] (STEWART) 15. Apparatus for drying bagasse (U. S. pat. 1,680,274). 1. Textile fiber from sugar cane (U. S. pat. 1,681,223) 25.

OWEN, B. J.: Desiccation of Sugar Beet and the Extraction of Sugar. London Min. Agr. and Fisheries. 84 pp. Reviewed in *Expt. Sta. Record* 58, 884(1928).

Sugar manufacture. ALOIS RAK. Fr. 634,135, May 10, 1927. A battery is made of diffusers and screw presses arranged alternately and in such a way that the juice circulates from the bottom to the top and the slices from the top to the bottom of the diffusers.

Treating sugar juices. DORR COMPANY. Fr. 633,946, May 5, 1927. To control the alky. of sugar juices during the process of defecation, use is made of the fact that the alky. is proportional to the elec. resistance, *e. g.*, a reversible motor controls a valve regulating the feed of the reagent, and is actuated by a suitable relay according to the fluctuations of an instrument indicating the variations produced in the resistance.

Purification of sugar juices. ELECTRO-OSMOSE A-G. (GRAF SCHWERIN GES.). Fr. 634,493, May 16, 1927. The juice is submitted to the action of a continuous elec. current between 2 diaphragms of the same elec. character, so that before the positive and negative electrodes so-called "negative diaphragms" are inserted, and the water which flows through the cathode chamber is caused to flow through the anode chamber.

Centrifuges for sugar. GABRIEL KREPELKA. Fr. 633,781, May 3, 1927. Constructional features.

Counter-current extraction apparatus for diffusion of sugar beets, etc. J. & F. HOWARD, LTD. and G. E. ROWLAND. Brit. 281,813, Oct. 7, 1926.

Removing hydrochloric acid from sugar solutions. FRITZ KOCH (to the International Sugar and Alcohol Co., Ltd.). U. S. 1,678,819, July 31. A sugar soln. contg. HCl, such as a soln. produced by the treatment of sawdust with HCl, is sprayed into heated air or oil to volatilize and remove HCl from the soln.

Starch from rice. OTTO JASCHKE. U. S. 1,681,118, Aug. 14. Rice grains are dry ground or crushed sufficiently to break down the starch cells and starch granules, so that the starch particles and glutinous particles of the grain may be quickly enveloped, permeated and satd. by treating liquids such as used in sepg. rice starch. An app. is described.

29—LEATHER AND GLUE

ALLEN ROGERS

Contribution to the study of the pickling of the hides. ENRICO SIMONCINI. *Boll. ufficiale staz. sper. ind. pelli mat. concianti supplemento tecnico* 6, 17-32, 35-48 (1928); cf. C. A. 22, 2487.—The expts. were made on samples of bison or cow hides. H_2SO_4 and NaCl were used as the constituents of the pickle. In pickling, the physicochem. state of the hide is altered by a specific action of the acid; within 30 min. the acid absorbed by the hide is in equil. with the acid in the soln. The intensity of absorption is proportional to the concn. of the acid. In solns. of equal concn., the absorption is proportional to the percentage of acid employed, calcd. on the wt. of hide. In presence of salt, the acid causes contraction of the tissues and synchronous dehydration of the fibers. If the increase of the liquid is considered as a measure of the intensity of the pickling, this value is nearly proportional to the amt. of acid fixed by the hide. Also, after the fixation of the acid is completed, the vol. of the pickle is still increasing; therefore, a prolonged pickling is recommended in practice. The absorption of salt is proportional to the initial concn. of NaCl in the pickle; an excess does not produce better results.

A new apparatus for determining the ethyl acetate figure of tannins. C. RIESS. *Collegium* 1928, 275.—An extn. vessel similar to that described by Procter (*Pocketbook* p. 53,) has a coarse glass filter fitted around the funnel which conveys the condensed ethyl acetate to the bottom of the extn. vessel. The solvent is broken up into small drops and extn. is therefore rapid.

A rational chemical analysis of synthetic tannins. (Technical condensation products of aromatic sulfo acids). I. BERKMANN AND A. KIPRIANOFF. *Collegium* 1928, 177-97.—The direct detn. as $BaSO_4$ of SO_4 in syntans is not possible because syntans prevent pptn. of $BaSO_4$. A soln. of 0.03 g. $Na_2SO_4 \cdot 10H_2O$ and 0.5 g. of Neradol FB in 300 cc. H_2O treated with $BaCl_2$ is clear even after warming for half an hr.; after cooling a milky ppt. seps. in 1 or 2 hrs. Several methods of removing the org. matter were tried; the following was most satisfactory. Mix 0.5 g. of powdered syntan and 8 g. of Na_2CO_3 in a Pt crucible, ignite gently at first and then fuse. Ext. the melt, oxidize by boiling 15 min. with Br, acidify with HCl, heat to remove Br and then ppt. with $BaCl_2$. This method was used to det. (a) total SO_2 ; (b) SO_2 in the ash of the carefully neutralized substance was also detd. (a) is SO_2 in both org. and inorg. combination; (b) is half that in org. combination plus the inorg.; half the org. is lost during ashing according to the

reaction, $2 \text{RSO}_2\text{Na} \rightarrow \text{Na}_2\text{SO}_4 + \text{SO}_2 + \text{R}_2$ where R is a syntan mol. Instead of neutralizing before ashing it is usually more convenient to titrate the syntan with 0.5 N alkali and methyl orange paper, calc. the acid as SO_3 and add this to the SO_3 found in the ash of the unneutralized syntan. If NaCl is present, moisten the syntan with H_2SO_4 , then ash and det. SO_3 . Ash another portion with soda, det. Cl in the ash and calc. and correct for the Na_2SO_4 formed from NaCl. All the Cl is assumed to be inorg.; data are given which support this view. From the SO_3 in org. combination and the neutralization figure the quantity of sulfo salt can be calcd. Analyses of 9 German syntans are given.

I. D. CLARKE

A new synthetic tannin: Alpha NK. VITTORIO CASABURI. *Boll. ufficiale staz. sper. ind. pell. mat. concianti* 5, 377-9(1927).—The by-products obtained in manufg cellulose treated according to the Italian-soda method are brought into reaction with a mixt. of phenols and homologous substances, instead of β -naphthol, which latter yields the tannin Alpha C. The new tannin, Alpha NK, tans skins even when employed alone; the color of the leather is uniform. An analysis of the tanning liquor gave these results: tanning substances 20.4, non-tans 17.0, H_2O 62.6%, d_{15} 1.18. For neutralizing 1 g. of liquor, 16 cc. N NaOH is needed.

GUNTHER SCHWOCH

Vegetable and synthetic tannins. O. GERNGROSS. *Papier-Fabr.* 26, 380-5 (1928).—An address. The chem. nature, sources, prepn. and testing of naturally occurring vegetable tannins are outlined. The color with which a dil (1:1000) soln fluoresces in ultra-violet light (cf. C. A. 22, 183, 419) is a valuable indication of the nature of the material. Synthetic tanning agents may be classified roughly as (I) condensation products of aromatic hydrocarbons, phenols, etc., (II) condensation products of carbohydrates, (III) oxidation products of brown coal, etc., and (IV) products obtained from sulfite waste liquor. Class II includes certain condensation products of cellulose esters.

R. H. DOUGHTY

The future of chestnut tanning materials. CHARLES R. OBERFELL. John H. Heald & Co., Lynchburg, Va. *Chem. Met. Eng.* 35, 468(1928).

E. H.

Process for tanning by means of the condensation products of phenols, their substituted derivatives or oxidation products, with aldehyde. CHARLES BLANC. *Bull. soc. ind. Mulhouse* 94, 359-64(1928). Sealed Note 1928, Sept. 9, 1909.—When phenols (or their substituted derivs. or oxidation products) are condensed with aldehydes under such conditions as to obtain sol. reaction products, the latter have valuable tanning properties. Report. LOUIS MEUNIER. Faculté des Sciences, Lyon. *Ibid* 364-7. Though the reaction of sol. phenol-formaldehyde condensation products with gelatin was known previously (Bayer, *Ber.* 5, 1904(1872); Nierenstein, *Collegium*, 1905, 221; 1906, 434; Stiasny, *Der Gerber* 31, 186, 202, 216, 231(1905); Kauschke, *Collegium* 1906, 351, 361; Weinschenk, *Chem.-Ztg.* 31, 349(1907)), its application to the tanning of hides was not systematically studied before B.'s work, Wolessenky's investigation coming much later (C. A. 20, 1336, 1535).

A. PAPINEAU-COUTURE

Clarification of waste tannery liquors and their utilization for agricultural purposes. V. HLAVINKA. *Sbornik Českoslovenké Akad. Zemědělské* 2, 41-54(1927).—The inorg constituents, with the exception of compds. of Cr and As, of tannery waste liquors are usually harmless, and no danger is likely to arise from bacteria unless pathogenic bacteria are present; these are only imperfectly removed by treatment with Cl or bleaching powder. To obtain efficient sedimentation the tanning liquors should be kept sep. from the lime-pit liquors. Sedimentation is carried out in sand pits and in raking plants where the chem. reactions are allowed to complete themselves so that coagulation of suspended matter is accelerated. The slime obtained contains 98% of the inorg. and 75% of the org. solids suspended in the liquors. The clarified liquors retain only 10% of the Cr content, while the slime has a N content of 5-6%. After drying to a water content of 60% it may be used as a fertilizer.

B. C. A.

Emulsions. E. STIASNY. *Collegium* 1928, 230-41.—A review of present theories of emulsions, introductory to further work. For fat-liquoring leather the emulsion must be stable enough to penetrate the leather but it must not be too stable for the oil must deposit in the leather.

I. D. CLARKE

Fat liquors and fat emulsions. HCH. ARNOLDI. *Collegium* 1928, 292-5.—General discussion of fat liquoring chrome leather.

I. D. CLARKE

Chromium-fatty acid compounds and their existence in leather. WILHELM SCHINDLER and KARL KLANFER. *Collegium* 1928, 286-91.—Four types of compds. were identified. Type a is formed as a violet sticky mass on boiling solns. of Cr alum with Na soaps. When dry it is a blue-green wax-like substance contg. about 7.2% Cr. It dissolves slowly in $\text{C}_2\text{H}_5\text{Cl}$. It is not hydrolyzed by boiling concd. HCl, only slowly by HCl in $\text{C}_2\text{H}_5\text{Cl}$, but at once by boiling 30% NaOH. Type b is pptd. from

cold solns. of soap and Cr alum. It forms a blue-green soln. in C_2HCl_3 . It changes into type *a* on standing and so is not important in leather technology. Type *c* is formed by treating boiling basic Cr alum solns. with soap. It could not be sepd. from the basic sulfate and $Cr(OH)_3$ ppt. Type *d* is formed by the action of oleic acid on cold freshly pptd. $Cr(OH)_3$. It contains about 16% Cr and is insol. in all solvents when dry. It is slowly hydrolyzed by boiling HCl in absence of C_2HCl_3 . Ten leathers were extd. with CCl_4 . All the exts. contd. Cr (0.4 to 1.7%). By treatment of the ext. with solvents small amts. of compds. richer in Cr could be sepd. but none as rich as in Cr as type *a*.

I. D. CLARKE

Dyeing of gloving and clothing leathers. M. C. LAMB. *J. Soc. Dyers Colorists* 44, 225-9(1928).—See *C. A.* 22, 2076.

Further studies of rubber under compression. C. H. BIRKITT and T. J. DRAKELEY. *Trans. Inst. Rubber Industry* 3, 462-7(1928).—In continuation of earlier expts. (cf. *C. A.* 20, 1920), the influence of the area and thickness of the test piece and of the friction between the compression plates and the upper and lower surfaces of the test

piece were investigated. The compression is proportional to the original thickness but corrections for area follow no definite law and must be detd. experimentally. The compression at given loads depends upon the lubricant. A general discussion follows.

C. C. DAVIS

Carbon blacks and their use in rubber. I. Comparative properties of blacks and tests in uncured rubber. NORRIS GOODWIN AND C. R. PARK. *Ind. Eng. Chem.* 20, 621-7(1928).—The phys. and chem. properties of 5 C blacks and of rubber mixts. contg. them were studied to det. the relative value of the individual blacks as pigments in tire treads. The blacks included: (1) "Charlton" lampblack, an oil black; (2) "Micronex," made by the channel process black for rubber; (3) "Super Spectra," made by the channel process for varnishes and enamels; (4) "Thermatomic," made by thermal decompn. of natural gas, and (5) "Goodwin," made by incomplete combustion of natural gas at high temps. The true d., apparent d., particle size and shape, x-ray structure, tinting strength, light scattering and absorption, extractable substances, adsorptive capacity, moisture content, oil absorption capacity, sedimentation max. capacity of incorporation in rubber, the behavior during the milling operation, the soly. of the resulting mixts. in C_6H_6 , the plasticity of these mixts. and their tendency to bloom were detd. II. Experiments in cured rubber. *Ibid* 706-15.—The 5 C blacks were tested in rubber mixts. with different accelerators to det. the phys. properties of a C black which are most responsible for the properties of rubber mixts. contg. the black. The relative properties of the mixts. were judged by stress-strain data, hardness and resistance to abrasion. The results indicate that particle size, adsorption capacity and the nature of the non-C components all play a part in detg. the phys. properties of a rubber mixt. contg. the C black. Of these the adsorption capacity has the most influence on the properties of rubber mixts. In all but 1 case, the higher the adsorption capacity the more the C black retarded the rate of cure. Resistance to abrasion does not vary directly with tensile strength or resilient energy, but is a complex function of the stress-strain curve and particularly of the hardness. Increased resistances to abrasion with increased proportions of C black indicate that a C black which is inferior to another in the same proportion may in larger proportions excel the other. The effects with stearic acid and with the individual accelerators are described in detail.

C. C. DAVIS

Effect of various types of carbon black on certain physical properties of rubber compounds. D. J. BEAVER AND T. P. KELLER. *Ind. Eng. Chem.* 20, 817-9(1928).—Tests of various C blacks in vulcanized rubber show that in general the presence of O in C black retards the rate of vulcanization in direct proportion to the quantity of O adsorbed by the black, and that O decreases the phys. properties obtainable with a given proportion of an accelerator. Furthermore, aging data show that the presence of O in the black increases the rate of deterioration, though this rate does not increase in direct proportion to the quantity of O. Therefore blacks which contain a relatively low proportion of O, such as "Thermatomic" black and acetylene black, give rubber mixts. with better aging properties than do blacks like lampblack and channel C blacks, which contain relatively large quantities of O. No correlation could be found between the acetone ext., I absorption and oil absorption of the blacks and the effects of the blacks on the rate of vulcanization and on the aging of the rubber mixts. contg. them.

C. C. DAVIS

The permeability of rubber and methods of testing it. H. A. DAYNES. *Trans. Inst. Rubber Industry* 3, 428-53(1928).—A crit. review and discussion of the phenomena of permeation, absorption, diffusion, equil. conditions, and the influence of various factors on permeation, diffusion and the time to reach equil., including the nature of the gas, the pressure, the thickness, the temp., the state of vulcanization, and the presence of compounding ingredients. The practical importance of these phenomena in the deterioration of air bags for curing tires, in tennis balls, inner tubes and balloons, in the vapor cure, in the Peachey process, in the natural and artificial aging of rubber, in connection with antioxidants, in rubber under expansion, in drying rubber, and in elec. insulation are then discussed. Finally methods of measuring the permeability of rubber to gases are described. The subjects are discussed from a critical point of view, with many original references, and certain new points of view are introduced. Stability toward O is of great importance in its influence on the life of rubber, but accessibility of O is sometimes of equal or greater importance. Balloon fabric may be stable for yrs. in darkness, but on exposure of one side to O for a few seconds, O passes through without chem. combination to the other side. In this case stability is the predominant factor. When rubber is heated, its rate of combination with O increases more rapidly than the diffusivity, and a condition is reached where the rubber can combine with more O than is available.

Under such conditions, when 2 rubber mixts. are equally stable, the one in which O diffuses more rapidly deteriorates the more rapidly, whereas the 2 mixts. deteriorate at the same rate at a lower temp. These conditions apply to the 70° air oven test, where the rate of deterioration is increased about 180 times and the permeability only 5 times. In aging tests with O under pressure at elevated temps., the concn. of O must be increased disproportionately to increase the rate of deterioration, and the increase of the concn. of O probably does not take the place of time for uniform penetration and leads to uneven oxidation. There is much to recommend a low concn. of O with slower deterioration, as in the Bruni test (cf. C. A. 16, 4093). The effect of an *anti-oxidant* on the accessibility of O depends upon whether it acts as an antioxygen, as defined by Moureu and Dufraisse, or is merely a preferential reducing agent. The latter would be very limited in its protective action at normal temps., whereas it would be effective in protecting rubber for short periods against high temps., as in dry heat cures, in hot water bottles, or in accelerated aging tests where accessibility of O plays an important part. A general discussion follows the paper. C. C. DAVIS

Softeners and antisofteners. FRLE C. ZIMMERMAN AND LESLIE V. COOPER. *Ind. Eng. Chem.* 20, 812-3(1928).—By measuring the plasticity of rubber before and after the addn. of a substance, the whole procedure being carried out under standardized conditions, it is possible to judge whether the substance softens or stiffens a rubber mixt. The relative effects of different softeners and stiffeners may also be detd. by this method. Stearic acid, pine tar, liquid asphalt, pine oil and degreas showed the greatest softening action of 14 softeners tested, while benzidine and *p*-aminophenol are among the substances found to have a distinct stiffening action. C. C. DAVIS

Machine for testing rubber products used to absorb vibration. FRANZ D. ABBOTT. *Ind. Eng. Chem.* 20, 853-7(1928).—A machine, termed a *compression flexometer*, for judging the resistance of rubber to prolonged vibration by its resistance to flexure while under compression is described and illustrated. Tests of rubber for shock insulators, motor supports and other objects which absorb vibration or undergo flexure while under compression show that the new method is a reliable indication of the behavior of the rubber in service. This is not true of elongation, tensile strength modulus and hardness tests or of static compression-set tests. C. C. DAVIS

Plasticity and elasticity of rubber. A. VAN ROSSEM AND H. VAN DER MEIJDEN. *Rubber Age* (N. Y.) 23, 438-40(1928).—See C. A. 22, 3063. C. C. DAVIS

The variability in the plasticity of plantation rubber. F. L. ELLIOTT. *Trans. Inst. Rubber Industry* 3, 468-79(1928).—The expts. are a part of the Ceylon Rubber Research Scheme. Comparative tests of the plasticity of raw rubbers, the same rubbers after mastication and after mixing with S showed that in most cases there is a definite relation between the plasticity of a raw rubber and its plasticity after mastication. With normal estate rubber, the plasticity of rubber-S mixts. was about 1.7 times that of the corresponding masticated rubber, but with special types, *e. g.*, sprayed latex rubber, this relation was not true. The rubbers were masticated with the same consumption of power in all cases, and the plasticity detns. were made on a Williams' plastimeter, and on a newly devised *extrusion plastimeter*, the construction and operation of which are described and illustrated. The vol. of rubber extruded per unit time is inversely proportional to the abs. viscosity, so D_{30} (de Vries) is inversely proportional to the 4th root of the vol. extruded. This extrusion method is therefore far more sensitive to differences of plasticity than is the parallel plate method, *e. g.*, 10% difference between D_{30} values (less than 0.1 mm.) corresponds to approx. a 45% difference in the rate of extrusion. With this procedure, it was found that the difference between the max. and min. values of crepe or of sheet is much greater than the difference between the mean values of the 2 types of rubber, *i. e.*, the differences in plasticity which depend upon the methods of prepn. of crepe and sheet are much smaller than those between individual samples. Sprayed latex rubber varied considerably and fine hard para was harder and less variable than crepe or sheet. The rate of vulcanization varied with the plasticity, the harder the rubber the more rapid its rate of vulcanization. By maturing rubber for different times, it was found that the state of maturation plays the predominant role in governing plasticity, an increase of maturation so slight that little change in the rate of cure was manifest, hardening the rubber 50%. The high values obtained by de Vries (*Mededeelingen* No. 46) for the viscosity of matured rubber with little change in the D_{30} values are contrary to experience of the Ceylon Research Scheme. The plasticity changes on keeping, and perhaps this accounts for the conflicting results. Machine-dried crepe averaged approx. 25% more plastic than that dried at av. temps., so that the temp. of drying influences the plasticity. Thus rubber dried at 180° F. was about twice as plastic as rubber dried at 140°. The smok-

ing process also increases the plasticity. A general discussion follows the paper.

C. C. DAVIS

Snow-white and bright-colored, non-poisonous, highly elastic rubber varnish with titanium dioxide. RUPPOLD DITMAR. *Chem.-Ztg.* 51, 506-7(1928).— TiO_2 gives excellent results when used as a pigment in white and bright-colored rubber varnishes.

C. C. DAVIS

The effect of antioxidants on the color of rubber mixts. T. L. GARNER. *Trans. Inst. Rubber Industry* 3, 417-27(1928).—Systematic tests of the color produced by antioxidants in different colored rubber mixts. were carried out. Preliminary tests showed that the same effects are manifest in cured and uncured mixts., so in most cases uncured mixts. were used. They were maintained (1) in air in darkness; (2) in air in daylight and (3) in N in daylight. The results show that in general uncured and cured rubber mixts. contg. antioxidants become discolored on exposure to daylight in air or in an inert gas, whereas there is little or no effect when they are kept in darkness in air. The color effect is only on the surface. The antioxidants tested were all aldehyde-amines, and the amine constituent may be responsible for the undesirable effects. Therefore the introduction of antioxidants of quite different chem. nature might furnish antioxidants which can be used in light-colored rubber products.

C. C. DAVIS

Vulcanization of rubber. NICHOLAS BACON. Cornell Univ. *J. Phys. Chem.* 32, 801-27(1928).—A review of theoretical and exptl. work on the nature of vulcanization indicates that there are at least 4 possible assumptions, that (1) "combination" of rubber and S is simply the formation of a solid soln., in which case it should be possible to ext. S by treating a vulcanizate with excess raw rubber in a suitable solvent; (2) vulcanization is simple adsorption or absorption accompanied by a chem. reaction, in either of which cases a vulcanizate should be heterogeneous and it should be possible to fractionate it by peptization in C_6H_6 and thus obtain fractions with different S contents; (3) the compn. or structure of rubber is altered by vulcanization, combination with S being only a secondary reaction, in which case it should be possible to induce vulcanization without the vulcanizing agent taking a part, and also to obtain raw rubber from vulcanized rubber; or (4) the rubber mol. is very large and forms a series of compds. with S, the larger the mol. the smaller the differences between 2 successive compds. and the more difficult their sepn. In the present work, these 4 theoretical possibilities were investigated experimentally to ascertain which is the most probable explanation of vulcanization. To test (1), hard rubber was extd. with acetone and was then heated to 190° with aniline contg. raw rubber in excess of that in the hard rubber. Though S is very sol. in aniline under these conditions, no S was extd. from the hard rubber, showing that "combined" S in hard rubber is more firmly held than in ordinary solid solns. According to (2), it should be possible to obtain soft vulcanized rubber from a mixt. of hard rubber and raw rubber provided their mutual adsorption could be effected, but after heating 15 parts of hard rubber with 85 parts of raw rubber at 150° , the 2 components could be sepd. by peptization in C_6H_6 . Likewise heating at 180° or 245° a mixt. of hard rubber and of excess raw rubber, each peptized in aniline, failed to yield a vulcanized product, and from the product obtained by evapn. the hard rubber was recovered by C_6H_6 (cf. *J. Soc. Chem. Ind.* 13, 14(1894)). Similarly, when a mixt. of hard rubber and raw rubber in xylene was refluxed, the raw rubber was sepd. from the solid product by peptization in C_6H_6 . The addn. of vulcanization accelerators and ZnO to mixts. of hard rubber and raw rubber, either in the solid state or peptized, did not bring about vulcanization. In the fractional peptization tests, mixts. contg. much less combined S than those of Stevens (C. A. 13, 3039) were used to ascertain whether even under such conditions homogeneity persisted. Rubber cured with different proportions of S was extd. with acetone and was then peptized in hot C_6H_6 and successive fractions were analyzed. All samples were homogeneous, including those which contained less than 0.1% "combined" S. With the aid of ultra-accelerators and ZnO, samples, which from a phys. point of view were well cured, were obtained which contained less than 0.5% S. Removal of protein did not influence the results with mixts. of raw and cured rubber. Further vulcanization tests showed that when coeffs. of vulcanization are very close together, e. g., 0.37 and 0.57% combined S, homogeneous mixts. cannot be obtained by heating them in peptized form. Homogeneous products were also obtained when mixts. cured below the m. p. of S were extd. with acetone and then

peptized in C_6H_6 . Accordingly even below its m. p., S is sol. in rubber. When sheet rubber was heated with a layer of S on one side, the surface in contact with S had a much higher coeff. of vulcanization than the part farthest from the S, and on fractional peptization fractions contg. different proportions were obtained. This proves that rubber is not composed of "giant" mols. Boiling $BuOH$ does not peptize rubber but dissolves S, so that equil. between resin-free rubber and S was studied in this solvent at 117° . Different concns. of S, i. e., different proportions based on the rubber, were used, and after drying *in vacuo* and extg. with acetone, the S content was detd. In all cases the rate of increase of S content diminished progressively until ultimately it became so slow that it could not be decided whether equil. had been reached or whether diffusion became so slow that the reaction was inhibited. The data show no evidence whatever of the formation of a chem. compd. up to the compd., $C_{10}H_{16}S_2$, which was formed in each case when sufficient S was present. The proportion of S combining with the rubber was practically proportional to the concn. of S. Because the soly. of S in rubber increased with increase in the coeff. of vulcanization, which in turn was counteracted by the lowered diffusion, there was probably a static condition reached which was a false equil. The results as a whole show that the union between rubber and S is chem., and that the theory of C. O. Weber is in modified form the most satisfactory for explaining vulcanization. Since fractional peptization shows that homogeneity exists even with a coeff. of vulcanization of 0.1%, the initial compd. of the Weber series must be wrong. The mol. wt. of the rubber hydrocarbon is at least 32,000 to account for the initial compd. of a series extending to a compd. contg. 32% S. This compd. would be $(C_6H_8)_{470}S$, and if analytical methods were more delicate, it might be found that homogeneity existed below 0.1% S; in which case the value of n in the initial compd. $(C_6H_8)_nS$ would be even greater than 470. C. C. DAVIS

Binding agent (from rubber) for colors, varnishes, etc. (U. S. pat. 634,275) 18. Oils resembling petroleum by destructive distillation of rubber (Brit. pat. 282,565) 22.

UTTÉE, A. J.: **Kautschuk**. Bearbejdet fra hollandsk af Frits Heide. Copenhagen: J. H. Schultz. 76 pp.

Rubber. HAROLD E. CUDE (to Naugatuck Chemical Co.). U. S. 1,680,862, Aug. 14. Commiunited rubber is treated with oleic or stearic acid or other org. acid capable of forming a water-sol. soap, until the mass has assumed a putty-like consistency, and residual acidity is neutralized with a base such as NaOH capable of forming a water-sol. soap. The product may be dispersed in aq. liquids.

Rubber. TECHNISCHE CHEMIKALIEN-COMPAGNIE G.M.B.H. Fr. 633,794, May 3, 1927. Rubber is treated before vulcanization with mineral oils contg. unsatd. compds. of S and OH and is characterized by the fact that the oils are activated by heating to $135-150^\circ$ and drying.

Treating rubber latex. W. A. GIBBONS (to Naugatuck Chemical Co.). Brit. 282,011, Dec. 9, 1926. Concd. latex contg. alkali preservative is neutralized or slightly "overneutralized" to improve its plasticity and cohesiveness on the mixing mill or other app. H_3PO_4 or $HOAc$ or a buffer material or salt which hydrolyzes to give an acid reaction such as primary Na phosphate or Zn acetate may be used.

Treating rubber latex. SIDNEY M. CADWELL (to Naugatuck Chemical Co.). U. S. 1,680,856, Aug. 14. In making various rubber articles, a rubber dispersion is treated with a metallic compd. such as ZnO and with NaOAc or other suitable org. acid salt capable of reacting to liberate metallic ions in the dispersion to form an uncoagulated compn. of increased filterability, and rubber is deposited from the latex thus obtained directly on a porous form in the shape of the desired article. U. S. 1,680,857 specifies prepg. a vulcanized latex by adding, to an approx. NH_3 -free latex contg. sufficient non-nitrogenous CS_2 accelerator, ZnO and S to cause the latex to be vulcanized to a soft elastic product, and then sufficient addnl. S, ZnO and tetramethylthiuramdisulfide to cause the rubber to be vulcanizable to a hard rubber at temps. below 100° . U. S. 1,680,858 specifies forming rubber articles from latex by vulcanizing the latex in the presence of a salt of a thiol acid such as Na dithiobenzoate and depositing the latex directly on a porous form.

Warming mill and associated apparatus for treating rubber stock. OSCAR D. HOLLENBECK. U. S. 1,680,171, Aug. 7.

Mold for rubber airbags, etc. LEON S. WASHBURN (to The Goodyear Tire & Rubber Co.). U. S. 1,679,554, Aug. 7. Structural features.

Apparatus for making seamless rubber tubing. CHARLES H. ROTH (to The Goodyear Tire & Rubber Co.). U. S. 1,679,545, Aug. 7.

Abrasion testing machine for testing rubber tire treads, etc. DUNLOP RUBBER Co., LTD., and L. J. LAMBOURN. Brit. 282,131, Sept. 1, 1926.

Coating metals with rubber. FRITZ AHRENS. Fr. 634,128, May 10, 1927. In coating metals with a soln. of rubber, the product obtained by treating oxidizable oils with sulfur chloride is added to the soln.

Rubberized fabric driving belts. C. MACINTOSH & Co., S. A. BRAZIER and T. E. ANDREW. Brit. 282,271, May 6, 1927. Driving belts, bands, ropes or the like such as those for use in textile machinery are immersed in a natural or artificial rubber dispersion, which may contain added compounding or vulcanizing ingredients, dried and vulcanized. The material may be preliminarily treated with dil. NH_3 soln. to render it more permeable, and may be alternately dipped in the rubber dispersion, and dried between dippings, to obtain any desired degree of rubberization. Vulcanization may be effected by steam or dry heat.

Rubber-composition flooring. JOHN B. LOSEY and WALTER R. STONE. U. S. 1,678,948, July 31. Structural features are specified of a material comprising a base of relatively soft rubber compn. and surface sections of harder rubber compn.

Treating waste material containing rubber and fiber. REED P. ROSE (to Mechanical Rubber Co.). U. S. 1,680,915, Aug. 14. Tire casings or similar waste material is disintegrated and worked mechanically with about 10% its quantity of a soap-forming fatty acid such as oleic or stearic acid until a mixt. of plastic, putty-like consistency is produced; NaOH in quantity 1.2-1.5 times that of the added fatty acid is then added, and the material is further worked and then beaten in an aq. medium contg. an alkali such as NaOH together with glue, casein or other protective colloid, until the rubber is completely removed from the fiber and in dispersed form.

Composition for softening and use as a filler in making vulcanized rubber mixtures. CLAYTON O. NORTH (to The Rubber Service Laboratories Co.). U. S. 1,679,000, July 31. A mineral lubricating oil of a viscosity of not over 120 sec. Saybolt at 38° is mixed with a small proportion of cotton seed oil.

Vulcanizing rubber. LORIN B. SEBRELL (to The Goodyear Tire & Rubber Co.). U. S. 1,679,548, Aug. 7. Vulcanization is accelerated by the use of mercaptoamino benzothiazole or other mercaptoarylthiazole, the aryl structure of which contains an amino group. Cf. C. A. 22, 2686.

Vulcanizing rubber coverings of rollers or other hollow articles. C. H. GRAY. Brit. 282,502, Sept. 24, 1926. Mech. features.

Plastic material from latex and asbestos. WILLIAM B. WESCOTT (to Rubber Latex Research Corp.). U. S. 1,680,234, Aug. 7. A product suitable for insulating wire is made by washing asbestos with acid and mixing it with latex.

CHEMICAL ABSTRACTS

Vol. 22.

OCTOBER 20, 1928

No. 20

1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

A large capacity laboratory extractor. F. E. HOLMES. Procter & Gamble Co. *Ind. Eng. Chem.* 20, 888(1928).—A 1 l. Pyrex flask serves to hold the boiling solvent; above this is placed a second 2-l. flask, connected to the first by a vapor line blown in the bottom of the second. The vapor line extends up almost to the top of the second flask. A small hole blown in the bottom of the vapor line returns the condensed solvent. A condenser is mounted on the top of the second flask. T. S. CARSWELL

A precision pipet viscometer. S. W. FERRIS. Atlantic Refining Co. *Ind. Eng. Chem.* 20, 974-7(1928).—The app. consists of an all-glass pipet with a carefully ground orifice, which is mounted in a water jacket which serves as a const. temp. bath. The capacity of the instrument is 4 to 5 cc. Calibration curves, Saybolt seconds being plotted against pipet seconds, are straight lines which intersect in one point on the Saybolt axis, thus making it possible to calibrate a pipet with one oil of known viscosity. The pipet may be calibrated with an accuracy of 1% by water alone. T. S. C.

A buret cleaner. F. H. FISH. Virginia Polytech. Inst. *Science* 67, 654-5(1928).—A method is given for cleaning a buret which is still unclean after trying chromic acid. After the buret is washed once with 95% EtOH, 2 cc. of this and 5 cc. concd. HNO₃ are added to it, a large test tube being placed over the open end. The reaction starts in a few min., throwing the contents up the full length of the tube repeatedly. At the end of the reaction the products are easily washed out, the buret being clean. J. B.

New continuous filters for sludges, etc. KURT W. GEISLER. *Z. Ver. deut. Ing.* 72, 1089-92(1928).—The construction of different types of vacuum drum filters are described. In one type the sludge is contained inside the rotating drum and in contact with a filtering screen so that its wt. aids the suction required to draw it through the screen; furthermore the tank ordinarily used as the liquid container in drum filters is here dispensed with. A filter especially adapted for *cellulose pulp* and one totally enclosed so that *filtration in an inert atm.* may be carried out are described. D. G.

Self-acting filtration apparatus. J. V. DUBSKÝ AND A. RABAS. Masarykova Univ. Brno. *Chem. Weekblad* 25, 293-4(1928). (In German).—A cylindrical glass vessel of 1000 cc., with a glass stopper at the bottom movable by a glass rod which emerges through a rubber stopper at the top, is used instead of a turned-over flask for const. supply of liquid to a filter. Ease of filling is thus obtained. J. GROSSFELD. *Ibid* 294.—The same result can be obtained by using a large separatory funnel with wide cock. B. J. C. VAN DER HOEVEN

Automatic supply of liquid. W. P. JORISSEN. *Chem. Weekblad* 25, 294-5(1928).—Old methods are described for liquid supply to a filter. B. J. C. VAN DER HOEVEN

The "A" tube—an improved form of "U" tube. A. O. JONES AND F. HOBSON. *Chemistry & Industry* 46, 1222-3(1927).—The app. consists of 2 pieces of glass tube which form an inverted V, joined near their lower extremities by a third tube so as to form an A. The lower ends of the first 2 tubes are closed with rubber stoppers, and the upper ends are drawn out to make connections for rubber tubes, or supplied with cocks. T. S. CARSWELL

The T. C. B. photo-colorimeter. J. PINTE. *Tiba* 6, 517-25, 637-47(1928); *Rev. gén. mat. plastiques* 4, 323-9, 410-3, 477-80(1928); cf. *C. A.* 21, 3492, 22, 1499.—A description of recent improvements in the instrument. A. PAPINEAU-COUTURE

A new turbidimeter. W. EWALD. *Instruments* 1, 371-5(1928).—Two light bundles from the same source pass through the app., 1 through the turbid soln. and the other through a standard adjustable turbid wedge, after which they are reflected onto a divided field, the halves of which are brought to the same intensity by means of the wedge and the results read from a scale. J. H. MOORE

Micro-apparatus for the determination of molecular weight by the cryoscopic method. KENJI IWAMOTO. *Sci. Repts. Tôhoku Imp. Univ.* 1st. ser., 17, 719-22

(1928).—The app. uses a Beckmann thermometer of reduced size, similar to that used in Pregl's ebullioscopic method, and the tube holding the solvent is so small that 1.5 cc. solvent will cover the bulb of the thermometer. The solvent tube is stirred with a Ni or Pt stirrer, and fits into a larger tube which serves as an air-jacket. The whole is immersed in a liquid 2–3° lower than the crystn. pt. of the solvent. From 7 to 30 mg. of solute are sufficient. T. S. CARSWELL

A new apparatus for a rapid sedimentation analysis. C. J. VAN NIEUWENBURG AND WA. SCHOUTENS. Tech. Univ., Delft, Holland. *J. Am. Ceram. Soc.* 11, 696–705(1928).—The app. is based on the detn. of the changes in concn. in one definite layer. The changes are measured by the changes in apparent wt. of a suspended body. C. H. KERR

An apparatus for continuous gas analysis. ERNEST C. WHITE. U. S. Bur. Chemistry and Soils. *J. Am. Chem. Soc.* 50, 2148–54(1928).—An app. is described for the continuous automatic analysis of gases, utilizing the change in elec. cond. of a soln. that has been exposed to the gas in a device for controlling the vol. ratio. A gas actually analyzed is CO in the presence of H₂ and hydrocarbons. Other gases capable of extn. are NH₃, HCl, SO₂, Cl₂, H₂S and CO₂. L. A. PRIDGON

A vacuum grating spectrograph for ultra-violet and soft x-rays. JEAN THIBAUD. *J. Optical Soc. Am.* 17, 145–54(1928); cf. *C. A.* 22, 1539.—Description of an app. for using ruled gratings at high glancing incidence, with 5 spectrographs and table showing wave lengths of lines for O, N, C, B, Fe, Mo, Ta, W, Pt and Au. J. H. MOORE

Direct-vision spectroscopic apparatus and monochromator with two prisms and constant deviation. C. LEISS. *Z. Physik* 47, 143–6(1928).—A direct-vision spectro-scope is described which can be used with either 1 or 2 prisms. Mirrors are mounted in permanent connection with the prisms, which can be adjusted together with one movement. It is so arranged that any line focussed on the cross-wires or on the emergence slit has passed through the prism with min. deviation. B. C. A.

Spectrometer or monochromator with lenses or mirrors for use with one or two prisms of glass, quartz, rock salt, etc. C. LEISS. *Z. Physik* 47, 137–42(1928).—A new form of const. deviation spectrometer is described which can be used according to requirements with 1 or 2 prisms of glass (for visible region), quartz (up to 4μ), or rock salt (up to 16μ). The arrangement of mirrors (or lenses) and prisms is such that the prisms are always used in the position of min. deviation. The instrument is very compact and simple of adjustment. B. C. A.

The condensate trap and its heat-technical significance. MAX BERGER. *Apparatebau* 40, 169–71(1928).—General remarks on heat losses due to inefficient traps, with descriptions of 2 types of Pieron traps. J. H. MOORE

An electrically heated furnace for organic combustions. MAX PHILLIPS AND R. HELLBACH. Bur. of Chemistry and Soils. *J. Assoc. Official Agr. Chem.* 11, 393–6(1928).—After briefly outlining the disadvantages of the ordinary 3-unit type of elec. combustion furnace, P. and H. describe a 4-unit furnace in which all the heating units are small, allowing of the use of a smaller combustion tube which permits C and H detns. to be made on 70–100 mg. samples if desired. A. PAPINEAU-COUTURE

Crucible melting furnaces. A. J. SMITH. *Met. Jurgist* (Suppl. to *Engineer* 146, No. 4) 101–3(1928).—An account of new designs used in Italy, France and England. D. B. DILL

An adjustable thermostat. BRADFORD NOYES, JR. *J. Optical Soc. Am.* 17, 127–31(1928).—A detailed description, with 2 cuts, showing connections of thermocouple, potentiometer, photoelec. cell, vacuum tube, relays, resistances and batteries. J. H. MOORE

A device for controlling the rate of cooling and heating of the Haughton-Hanson thermostat. J. D. GROGAN. *J. Sci. Instruments* 5, 217–9(1928).—An electrolytic cell delivers O at a steady rate to the thermostat bulb to regulate cooling, or to a bulb on the other side of the Hg relay to regulate heating. J. H. MOORE

WRIGHT, LEWIS: *The Microscope: A Practical Handbook*. Enlarged and re-written by A. H. Drew. London: R. T. S. 293 pp. 7s. 6d., net.

Filters. SOC. ANON. DES CHARBONS ACTIFS E. URBAIN. *Brit.* 283,192, Jan. 8, 1927. Capillary filters for liquids are formed of wicks of fibrous material or of material such as C, SiO₂, wood, powd. glass or resin, packed in siphonic tubes or agglomerated in the form of a siphon. By washing with suitable agents the capillary material may be given a charge corresponding to that of the particles to be sepd.

Hydrometer. LEO EDELMANN (to E. Edelmänn & Co.). U. S. 1,683,452, Sept. 4. Structural features.

Hygrostat. GEORGE R. LAWRENCE. U. S. 1,682,915, Sept. 4. Structural features.

Gasometer with sliding disk. MASCHINENFABRIK AUGSBURG NÜRNBERG A.-G. Fr. 635,061, May 27, 1927.

Rotating-disk photometer. CARL W. KEUFFEL (to Keuffel & Esser Co.). U. S. 1,682,528, Aug. 28.

Röntgen-ray apparatus. W. OTTO. Brit. 283,106. Jan. 3, 1927.

Meter for proportioning the flow of fluids. FREDERICK N. CONNET (to Builders Iron Foundry). U. S. 1,681,762, Aug. 21.

Filter and settling chamber for separating dust from air, etc. H. WARING AND ASSOCIATED LEAD MANUFACTURERS, LTD. Brit. 282,849, Aug. 28, 1926.

Apparatus for removing dust from air or other gases by centrifugal action. H. G. KAMRATH (to A. C. Spark Plug Co.). Brit. 282,726, Dec. 29, 1926.

Centrifugal apparatus for separating dust from air or other gases. GEORGE KEITH (to James Keith & Blackman Co., Ltd.). U. S. 1,682,285, Aug. 28.

Apparatus for liquefying and separating constituents of air or other gases. STUDIEN GES. FÜR GAS-INDUSTRIE. Brit. 282,813, Dec. 29, 1926.

Apparatus for liquefaction and rectification of air or other gases. W. L. DEBAUFFRE (to S. G. Allen). Brit. 283,101, Jan. 3, 1927.

Apparatus for humidifying air or other gases. BRITISH ARCA REGULATORS, LTD. AND T. LINDSAY. Brit. 282,915, Oct. 9, 1926.

Apparatus for controlling the mixture in suitable proportions of gases such as air and fuel for furnaces. CHARLES H. SMOOT. U. S. 1,682,689, Aug. 28.

Gas purifier construction. H. H. HOLLIS. Brit. 283,283, Oct. 8, 1926.

Reversing valve construction for gas purifiers. H. H. HOLLIS. Brit. 282,943, Nov. 9, 1926.

Gas cooling and washing apparatus. METALLBANK UND METALLURGISCHE GES. A.-G. Brit. 282,939, Nov. 3, 1926.

Gas washing apparatus. W. C. HOLMES & Co., LTD., C. COOPER and D. M. HENSHAW. Brit. 283,028, April 13, 1927.

Apparatus for obtaining mixtures of gases, particularly for anesthesia. ROBERT MARCEL MACHAVOINE and LUCIEN LOUIS GIRARD. Fr. 635,092, May 27, 1927.

Apparatus for feeding air mixed with steam into furnaces. HENRY MARCU. Fr. 635,116, May 28, 1927.

Furnace for annealing articles in an inert atmosphere. AKT.-GES. BROWN, BOVERI, ET C^{IE}. Brit. 282,799, Dec. 27, 1926.

Furnace construction with silicon carbide or similar heat-radiating flues, combustion chambers, etc. C. E. HAWKE (to Carborundum Co., Ltd.). Brit. 282,720, Dec. 27, 1926.

Retort furnace (with superposed horizontal heating chambers) for heating pulverized fuels and treating them with water, steam or air. H. A. PROCTOR. Brit. 283,388, April 30, 1927.

Ducts and ovens for baking varnished wires. FERDINAND HANFF (to Siemens-Schuckertwerke G.m.b.H.). U. S. 1,682,123, Aug. 28. Structural features.

Tubular system heat-exchange apparatus. O. SIMMEN. Brit. 282,717, Dec. 28, 1926.

Heat-exchange apparatus suitable for fractional condensation, etc. CARL F. BRAUN. U. S. 1,683,236, Sept. 4.

Apparatus for utilizing solar heat for heating water, etc. F. MARGUERRE. Brit. 282,773, Dec. 23, 1926.

Liquid heating apparatus. ALBERT JOHN LAMBERT and THE LAMBERT HEATER AND ENGINEERING COMPANY, LIMITED. Fr. 635,065, May 27, 1927. The liquid passes through shallow rectangular cells heated by flame or internal elec. resistances.

Carbide-feed acetylene generator. D. A. BROWN and A. F. DRINKWATER. Brit. 282,886, Sept. 29, 1926. Structural features.

Multiple-chamber continuous kiln construction. A. E. OSMAN. Brit. 283,009, Feb. 19, 1927.

Apparatus for controlling the flow of water or other fluids by temperature and pressure variations. RICHARD E. B. WAKEFIELD (to Westinghouse Electric & Mfg. Co.). U. S. 1,683,317, Sept. 4.

Apparatus for spray desiccation of milk or other liquids. WM. D. CALLAN (to Economic Powdered Products Co.). U. S. 1,682,596, Aug. 28.

Apparatus for treating milk or other liquids with ultra-violet rays. FRANZ HOFFMANN. U. S. 1,681,538, Aug. 21.

Apparatus for purifying dry-cleaning liquids. MAURICE M. SCHWAB and SAMUEL S. SCHWAB. U. S. 1,682,939, Sept. 4.

Apparatus for generation and distribution of mercury vapor ("mercury boiler"). FRANK SHORT (to Chemical Machinery Corp.). U. S. 1,683,310, Sept. 4.

Catalytic apparatus suitable for vapor phase reactions. ALPHONS O. JAEGER (to Selden Co.). U. S. 1,682,787, Sept. 4. A catalytic material such as a Pt or V catalyst is arranged in an annular layer and reaction gases such as SO_2 or C_2H_2 or C_4H_{10} vapor may be passed through the layer of catalyst at approx. at right angles to its axis, through perforated cylinders.

Centrifuge for the purification of oil. AKTIEBOLAGET SEPARATOR. Fr. 634,903, May 24, 1927.

Grinding and separating apparatus for minerals, coal, etc. PAUL LOUIS CROWE. Fr. 635,083, May 27, 1927.

Surface condensers. SOCIÉTÉ ANON DES ATELIERS DE CONSTRUCTIONS MÉCANIQUES ESCHER WYSS & C^{IE}. Fr. 634,904, May 24, 1927. An arrangement of the cooling tubes and flow plates for the condensed liquid is described by which max. efficiency from the cooling tubes is obtained.

Apparatus for "magnetic analysis" of drills or similar articles. THOMAS SPOONER (to Westinghouse Elec. & Mfg. Co.). U. S. 1,682,435, Aug. 28.

Apparatus for making coffee, tea or other extracts, infusions, decoctions, etc. LOUIS M. POUGER. U. S. reissue 17,077, Sept. 4. The original pat., No. 1,556,026, was issued Oct. 6, 1925.

Apparatus for extracting mucilage from flaxseed (for use in steam boilers). JOSEPH F. SANFTLEBEN (to Filtrators Co.). U. S. 1,683,102, Sept. 4.

Apparatus for drying paste, etc. JEAN B. VERNAY. U. S. 1,681,690, Aug. 21.

Apparatus for diffusion treatment of sewage or other materials. LORENZO S. WASHBURN (to Norton Co.). U. S. 1,681,890, Aug. 21. A porous diffusion plate for use in the bottom of the app. is formed of granular material such as cryst. Al_2O_3 bonded by a vitrified ceramic material and having the walls of its pores treated with a water-repellant substance such as paraffin.

Electric discharge device. A. W. HULL (to British Thomson-Houston Co., Ltd.). Brit. 282,766, Dec. 23, 1926. The cathode of a rectifier or lamp consists of a tube of Ni, Ni alloy or Mo open at one end and coated internally with one or more of the alk. earth metal oxides, oxides of rare earth metals such as Ce or with misch metal. A cylindrical anode of Ni, Mo or C closely surrounds the cathode and retains its heat and a heating coil of W insulated by thoria or MgO is supported within the cathode. Particles of the coating driven off from the cathode are deposited again inside the cathode. A bulb filling of rare gases such as A or Ne is used at a pressure of 1-100 microns or a small quantity of Hg may be inserted in the bulb. Various other structural details are described.

Thermionic valves with four electrodes. MARCONI'S WIRELESS TELEGRAPH CO., LTD. Fr. 634,648, May 3, 1927.

Thermostatic device for electric circuits. HARRY C. MILLER and AUGUST J. MOTT LAU (to Westinghouse Elec. & Mfg. Co.). U. S. 1,682,395, Aug. 28.

Thermostatic control device for electric circuits. REUBEN S. TICE (one-half to Arthur L. Holcomb). U. S. 1,681,446, Aug. 21.

Thermostat for control of electric circuits. HERBERT J. SAUVAGE (to Drying Systems, Inc.). U. S. 1,683,264, Sept. 4.

Thermostatic valve suitable for regulating fuel supplied to water heaters. LORAN F. DOGN (to Cleveland Heater Co.). U. S. 1,683,172, Sept. 4.

- Liquid stars and atomic volume. A. S. EDDINGTON. *Nature* 121, 496(1928). H. G.
- Liquid stars and atomic volume. J. H. JEANS. *Nature* 121, 496-7(1928). H. G.
- The atomic weight of protactinium. FRANZ LOTZE. Univ. Göttingen. *Naturwissenschaften* 16, 558(1928).—By analysis of at. wt. detns. of radioactive Pb a mixt. of Ra G, Act D and Th D and possibly some "ordinary" Pb the attempt has been made (cf. C. A. 22, 2106) to find the at. wt. of Act D. From 6 values the av. is 207.42, corresponding to an at. wt. of protactinium of 231. B. J. C. VAN DER HOEVEN
- Discrepancies in Moseley's law. V. DOLEJŠEK. *Z. Physik* 46, 132-41(1927).—It is shown that for the homologous elements of at. no. 36, 54 and 86, the value of $\sqrt{\nu/R}$ is given by the empirical expression $a + bN + cN^2 + dN^3$, where N is the at. no. and a, b, c, d are consts. The difference between the exptl. value of $\sqrt{\nu/R}$ and that calcd. from the above empirical expression is shown to be a periodic function of the at. no. B. C. A.
- Density and axial relations of hexagonal silver iodide determined with Röntgen rays. N. H. KOLKMEIJER, W. J. D. VAN DOBBENBURGH AND H. A. BOEKENOOGEN. *Verslag Akad. Wetenschappen Amsterdam* 37, 481-94(1928).—AgI, prepd. for another study, was purified and a d. 5.683 was finally obtained. Since the d. did not change any more by further purification, it was assumed that the crystals were physically pure. To check this assumption, the d. was calcd. from x-ray measurements and found the same. Conclusion: The sample was physically pure cubic AgI. Similarly, a d. 5.49 was found for hexagonal AgI. Changes in d. are attributed to vacuoles. A. L. H.
- The structure of silver subfluoride, Ag₂F. H. OTT AND H. SEYFARTH. Univ. München. *Z. Krist.* 67, 430-3(1928).—Ag₂F was prepd. by evapn. or electrolysis of H₂O soln., the latter giving greenish metallic hexagonal plates. No lines were found in x-ray patterns for either Ag or AgF. The structure is of the CdI₂ type, hexagonal, with $a = 3.0$ and $c = 5.14$ Å. U. There is 1 mol. in the cell, with F at 000, and Ag at $1/3, 2/3, p; 2/3, 1/3, -p$, where $p = 0.306$. L. S. RAMSDELL
- The lattice-plane contraction of crystal faces. WERNER BRAUNBEK. Techn. Hochsch. Stuttgart. *Naturwissenschaften* 16, 546(1928).—The Davison-Germer contraction effect has been explained previously by Bethe (C. A. 22, 538, 2511). H. calcs. for a NaCl crystal the amt. of actual contraction which can be expected. The lattice planes are stiff, and the mutual forces are composed of Born's at. forces (Coulomb attraction, r^{-8} repulsion, β factor of $-1/2$). For the widening of the surface plane relative to the internal planes the following values are found: no. 1 —0.0030, no. 2 +0.000001, no. 3 —0.000005, no. 4 —0.000001, no. 5 —0.000004. Because of an actually more rapid decrease of the repulsive forces (cf. Unsöld, C. A. 22, 536) it is probable that the contraction diminishes considerably faster toward the inside. Only the first value of 0.3% is of practical significance. Its influence on electron scattering will be negligible anyway. B. J. C. VAN DER HOEVEN

Crystal structure of urea and the molecular symmetry of thiourea. STERLING B. HENDRICKS. Rockefeller Inst. *J. Am. Chem. Soc.* 50, 2455-64(1928).—The crystal structure of $\text{CO}(\text{NH}_2)_2$ has been detd. by the use of Laue and spectrum photographs. The unit of structure contg. $2\text{CO}(\text{NH}_2)_2$ has d_{100} 5.73 A. U. and d_{001} 4.77 A. U. The space group is $4d - 3 (\sqrt{2})$ with O and C at $(c) 0\frac{1}{2}, \frac{1}{2}, 0$; and N at $(e) u, \frac{1}{2} - u, v; \frac{1}{2} - u, u, v; u, u + \frac{1}{2}, v; u + \frac{1}{2}, u, v$. The probable parameter values are u_N 0.13 \pm 0.01, v_N 0.20 \pm 0.02, v_O 0.32 \pm 0.02 and v_O 0.57 \pm 0.03. Laue and spectrum photographs were made from crystals of thiourea. The unit of structure contg. $4\text{CS}(\text{NH}_2)_2$ has a_0 5.50 A. U., b_0 7.68 A. U. and c_0 8.57 A. U. The space group is $2D_2 - 16 (\sqrt{2})$ with S and C at $(c) 0uv, \frac{1}{2}, \frac{1}{2} - u, v; 0, u + \frac{1}{2}, \frac{1}{2} - v; \frac{1}{2}, v + \frac{1}{2}$ and with N in the general positions. The mol. symmetry is that of the point group $2c$ (Cs) which has a plane of symmetry. C. J. WEST

An old experiment on collisions of the second kind. J. RUD NIKLSEN. Univ. of Oklahoma. *Science* 67, 651(1928).—Gooch and Hart (*Am. J. Sci.* 42, 448(1891)), observed that Na in a flame increases the intensity of the red K doublet. They dipped a helix of Pt wire into a KCl and NaCl soln., dried and then ignited it in the outer zone of a Bunsen flame. The K line, observed through a spectroscope and so fitted with a telescope that the Na doublet falls outside the field of view, increases in intensity with the Na concn. of the soln., reaching a max. when the ratio of Na to K is 100. An explanation of the phenomena is most likely to be found in the theory of at. collisions of the sec. kind (Klein and Rosseland, *C. A.* 15, 1654; Franck, *C. A.* 18, 1241). The Na atom, whose resonance potential is greater than that of the K atom, imparts some of its energy to the latter on colliding with it, thus increasing the intensity of the K doublet. J. BALOZIAN

Influence of electrolytic ions upon the moisture of steam (analog of Wilson cloud experiment). ARTHUR W. EWELL. Worcester Polytechnic Inst. *Phys. Rev.* 29, 912(1927).—The breaking of bubbles of vapor at the free surface of a liquid always throws some of the liquid into the vapor space. If the vapor is drawn away continuously, some of this liquid accompanies it. Increase in d. and viscosity increase the effect, but the presence of electrolytic ions decreases it. W. W. STIFLER

The vapor pressure of binary liquid mixtures. II. J. BROWN. *J. Soc. Chem. Ind.* 46, 482T(1928); cf. *C. A.* 19, 1800.—The following errata occur in the previous section of this series: equation (1) should read: $P'_m = P_a (1 - e^{-\Delta\gamma_a/RT}) + P_b (1 - e^{-\Delta\gamma_b/RT})$, whence $\Delta P_m = P_a c_a [1 - (1 - e^{-\Delta\gamma_a/RT})/c_a] + P_b c_b [1 - (1 - e^{-\Delta\gamma_b/RT})/c_b]$, where P'_m is the total vapor pressure of the mixt. at temp. T ; P_m is the divergence of P'_m from the simple mixt. law; c_a and c_b are the fractional concns. of components a and b of the mixt.; P_a and P_b are the vapor pressures of the pure substances a and b at temp. T ; λ_a and λ_b is the latent heats of vaporization of a and b in the mixt. The applicability of the formulas previously derived to a non-volatile solute is given. Equation (8) of the previous paper should read: $P'_m = P_a + (P_b - P_a) [(c_b - k)^n - k^n] / [(1 - k)^n - k^n]$. J. H. PERRY

Unimolecular films. B. C. J. G. KNIGHT AND P. STAMBERGER. Univ. College, London. *Nature* 122, 97(1928).—The suggestion of Sheppard and Keenan (*C. A.* 22, 3327) that the low values for the film thickness of cellulose esters on Hg are due to the formation of chains or sheets of polymerized mols. is supported by expts. with vulcanized triolein and a series of polymerized products obtained from it. With increasing degree of polymerization the thickness of the film on water is practically const. at 14 to 16 A. U. Triolein gives 13.0 A. U. From these and other measurements with the vulcanized fatty acids obtained on sapon., it is concluded that in the polymerized compds. the mols. are joined and definitely oriented in long chains, leaving the polar groups unaltered. F. A. JENKINS

Adhesion. II. (SIR) W. B. HARDY AND (MISS) M. E. NOTTAGE. *Proc. Roy. Soc. (London)* A118, 209-29(1928); cf. *C. A.* 20, 3605.—Measurements of the tensile strength of a solid joint between a steel or Cu cylinder and plate are described. The joint was formed by melting solid paraffins, fatty acids, or alcs. on the plate, allowing some of the liquid to be drawn under the cylinder by capillary attraction and then freezing it. A microscopical examn. of the disk of "lubricant" found on either the plate or cylinder on breaking the joint supports the view that it is composed of a central plate of flat crystals between 2 primary layers, one on each of the enclosing solids. The break appears to occur at one or both of the surfaces between the primary film and the plate of crystals. The effect of added impurity on the strength of the joint, and the position of the surface of break was investigated and the relation of the adhesion to the temp., pressure, chem.

compn. of the lubricant and compn. of the cylinder and plate is discussed. As in the case of static friction, the adhesion varies linearly with the mol. wt. of the lubricant for a given chem. series. The distance between the surfaces of the cylinder and plate, measured by means of a specially constructed spherometer, was found to be independent within the limits of error, of the nature of the lubricant and of the enclosing solids. A few measurements are recorded of the tangential pull required to break a joint. The fracture occurs at the same surface as with a normal force. B. C. A.

The relationship between crystal structure and the rate of adsorption of hydrogen on palladium, iron and nickel. G. TAMMANN AND J. SCHNEIDER. *Z. anorg. allgem. Chem.* 172, 43–64 (1928).—The rate of adsorption of H by Pd foil was measured at 100, 150 and 200°. Exposure to air of foil contg. dissolved H caused a marked diminution of adsorption rate. The rate was not affected by air exposure if the foil were H-free. The effect of air is undoubtedly connected with the presence of H₂O mols. in the crystal lattice. The rate of adsorption on O-free foil was dependent on the previous thermal treatment of the foil. Rapid adsorption occurred after heating to 400°, but the rate decreased if preliminary heating were carried to higher temps. The rate measurements were correlated with known changes in crystal structure of heated Pd foil. It is concluded that the max. rate of adsorption of both mol. and at. H occurs on the icositetrahedron planes of the crystals. The max. adsorption rate for electrolytic Fe foil accompanied preliminary heating to 300°. As with Pd, changes in crystal orientation accompanying preliminary heating above 300° decreased the adsorption rate. With Fe conversion to the γ modification exerted a still more marked decelerating effect. The rate of adsorption by Ni foil at 200° was greater than with Fe. No measurements were made with Ni that would permit correlation of crystal structure changes and adsorption rates. Adsorption of electrolytically evolved H on Ni and Fe cathodes at 20° was quite different from adsorption of gaseous H. Preliminary heating of the cathodes had the opposite effect on the rate of adsorption. The adsorption of electrolytic H represents a diffusion of H atoms into the metal, while with gaseous H the mols. must first be transformed to atoms before diffusion takes place. R. L. DODGE

Comparative adsorption by active charcoal. II. Isoelectric point of charcoal. O. SPENGLER AND E. LANDT. *Z. Ver. deut. Zucker-Ind.* 1928, 81–98; cf. *C. A.* 22, 178.—The charcoal is added to a series of buffer solns. at various p_H values, and the isoelec. point of the charcoal is taken to be the p_H value of the buffer soln. which is not changed by the addn. of the charcoal. The isoelec. points so obtained fell between p_H 5.7 and 8.7. B. C. A.

Adsorption of ammonia, carbon dioxide, benzene and acetone vapor by titanium oxide and stannous oxide gels. N. I. NIKITIN AND V. I. YUR'EV. *Z. anorg. allgem. Chem.* 171, 281–4 (1928); cf. *C. A.* 20, 3615.—The adsorption of C₂H₆ and (CH₃)₂CO by TiO₂ and SnO₂ gels was detd. by the dynamic method; that of NH₃ and CO₂ was detd. by the static method. At 1 atm., and 16° TiO₂ adsorbed 8.5% of its wt. of NH₃; SnO₂ about 1/4 as much. At 14.9° TiO₂ adsorbed 32% of its wt. of C₂H₆ while at 25° it adsorbed 30.4% of its wt. of (CH₃)₂CO. R. L. DODGE

Adsorption of gas on the faces of heteropolar crystals. J. H. DE BOER. N. V. Philips Gloeilampenfabrieken, Eindhoven. *Physica* 8, 145–56 (1928).—The residual field on the surface of heteropolar crystals can attract neutral atoms or mols. by dipole induction and thus hold them adsorbed. The theory is worked out for CaF₂ and I, CaF₂ being assumed to have on its surface a two-dimensional lattice of Ca⁺⁺ and F⁻ ions. For α the polarizability of the I atom, p the induced I dipole moment and r the distance between F and Ca, the energy liberated on adsorption of one I atom will be $\varphi = -(S\epsilon p/r^2) + (p^2/2\alpha)$; for $\delta\varphi/\delta p = 0$, the equilibrium position, $\varphi = -S^2\epsilon^2\alpha/2r^4$. The factor S , a numerical const., includes the action of + and - ions all over the surface. Its value drops rapidly for distances larger than r from the I atom. Assuming $\alpha = 5 \times 10^{-24}$ for I, estd. from the Fajans and Gross value (7.5×10^{-24}) for gaseous undeformed I⁻, $r = 1.93 \times 10^{-8}$ cm. for CaF₂, the Ca-I distance = 1.25 r (from ion radii of Ca and I) and the resulting $S = 0.36$, the energy $\varphi = 7600$ cal. heat of adsorption per g. atom is found, and $p = 2.3 \cdot 10^{-18}$ e. s. u. (equal to H₂O dipole moment). This adsorption can be continued in more than one I layer by dipole induction as long as the mols. are close enough together. For considerable distances between the (preformed) dipoles (e. g., for fatty acids) only unimol. layers can be formed. For I₂-CaF₂, the energy will be less than calcd. because of mutual repulsion of the I dipoles, the estd. value being 3450 cal.; including the reaction of the successive layers it will be about 3750 cal. The dipole moment decreases with every layer so that for the n th layer $P_n = k^{n-1}P_1$ (k includes r , α and S), also $\varphi_n = (k^2)^{n-1}\varphi_1$. The heat of evapn. of the adsorbed substance will increase by the adsorption thus: $\ln \pi = -(\varphi_1 + \varphi_n/RT) + B$ for π the

vapor pressure. For a satd. vapor pressure of π_0 , $\ln \pi/\pi_0 = -\varphi_n/RT = C k_1^{n-1}$. This represents an adsorption isotherm with 2 consts. c and k_1 for adsorption in multimol. layers. Expts. on this theory were made by evapg. I_2 in an evacuated tube on to a thin (invisible) CaF_2 film, which covered part of the wall. The I_2 in an extension of the tube was first cooled in liquid air; after heating to 0° the I_2 began to appear as a brown layer on the CaF_2 , at room temp. and it distd. all through the tube. By regulating the I_2 temp. π could be found and the amt. m of the I pptd. detd. analytically. Several isotherms were so detd., and curves are shown for a glass surface of 75 sq. cm. covered with 7.5 mm. CaF_2 . Even if the CaF_2 surface is unknown, still $\ln(\pi/\pi_0) = c/k_1^m$ will hold, i. e., $m = f\{\log[-\log(\pi/\pi_0)]\}$ is a straight line. This was completely confirmed; the equation $-am + b$ for this line had a const. $b (= \log_{10} \varphi_1/4.57T)$ which yielded a φ_1 of 3500 cal. per g. atom, agreeing well with the theory. Decreasing the amt. of CaF_2 finally leads to a convergence of a (0.2 mg. CaF_2 per 75 sq. cm. glass), probably due to the formation of a compact CaF_2 film (no pores) of const. surface (80×10^{-8} cm. thick); the I layer was calcd. from data of this type to be 30 mols. thick. It is typical for the isotherms that they run up rapidly for π/π_0 close to one. Previously this has been attributed to condensation in capillaries (Hückel). Results for thin (compact) CaF_2 surfaces with few capillaries are contrary to this view. Conclusion: A less pronounced rise of m with π/π_0 is due to filling up of capillaries, which decreases the effective surface. For thick CaF_2 layers deviations in b are more pronounced in a less ideal condition. Adsorption on powders is for the same reason less typical. The adsorbed I layer is brown because of a shift in spectrum toward short λ caused by the polarization. The spectrum begins at 6000 A. U., with a max. at 2950.

B. J. C. VAN DER HOEVEN

Structure in colloidal solutions. H. ZOCHER. *Collegium* 1928, 203-8.—A lecture giving a general discussion of the optical character of certain colloidal sols. I. D. C.

Studies on cerium hydroxide sols and gels. B. N. DESAI. *Kolloidchem. Beihefte* 26, 422-39 (1928).—Ce hydroxide sols were prepd. by dialyzing an NH_4 soln. of $Ce(NO_3)_3$. The sols set to gels when cooled or when electrolytes were added. The vapor pressure-concn. relation is given. The viscosity of the sol. increases as a linear function of the time of dialysis within the limits of the expts. Viscosity-concn. curves are irregular in shape. Heating the sol above 40° decreases the viscosity of the sol permanently. The sol-gel transformation is thought to be caused by an increase in the hydration of the micelle following increased elec. charge.

J. G. McNALLY

The influence of concentration of a sol on its stability. SUBODH GOBINDA CHAUDHURY. Univ. College of Science, Calcutta. *J. Phys. Chem.* 32, 1231-5 (1928).—Previous explanations of the effect of diln. of a sol on its stability have failed to take into consideration the fact that there is a decrease in charge on the particle as well as a decrease in surface and increase in the distance between the particles. The first 2 of these changes tend to make the sol unstable toward coagulation by electrolytes, provided it is assumed that the potential at which a sol coagulates does not change on diln. of the sol and that the relative adsorption of all ions on the surface remains the same. The greater distance between the particles of the dild. sol tends to make it more stable. That, in a no. of cases, the sol becomes unstable on diln., is presumably due to the preponderance of the first 2 effects over the third. When the ratio of the amt. of adsorption of similarly charged ions to that of the pptg. ions increases, another factor enters which tends toward greater stability. This increase in adsorption is probably due to the greater adsorbability of similarly charged ions.

H. F. JOHNSTONE

The coagulation of thorium hydrosols by electrolytes. B. N. DESAI. *Kolloidchem. Beihefte* 26, 357-421 (1928).—The velocity of the coagulation was detd. by an optical method and found to follow Smoluchowski's law for rapid coagulation. When dialyzed well enough to remove peptizing agents, the sols followed the Schulze-Hardy rule. This rule failed with the chlorides of the alkali and alk. earth metals where the salts formed the series $Li < Na < NH_4 < K$ and $Mg < Ca < Sr < Ba$ in their ability to stabilize the sol. It is suggested that stabilizing ability is a function of the valence and migration velocity of the ion. Ionic antagonism was found with $KCl + HCl$, $KNO_3 + HCl$, $K_2SO_4 + HCl$ and $LiCl + BaCl_2$.

J. G. McNALLY

Motion of sub-microscopic silver particles in gases. O. TRAUNER. *Z. Physik* 46, 237-52 (1927).—The rate of fall of Ag particles, 1.16×10^{-8} – 4.13×10^{-8} cm. in diam., in N has been examd. by Ehrenhaft's method. The results show that the velocity of fall is normal and that particles produced from Ag vapor or from a low-tension Ag arc are spherical and of normal d. The elec. charge carried by such particles is generally less than the electron charge; the min. value observed is 1.13×10^{-10} e. s. u.

B. C. A.

Influence of hydrogen and hydroxyl ions on colloidal systems. M. P. VENKATARAMER. *J. Mysore Univ.* **1**, 183-6(1927).—The distinctive properties of H and OH ions with respect to the stability of colloids are due to the fact that many substances adsorb water and that the outermost hydration layers are slightly dissoed. The changes in stability are due to the neutralization of either H or OH ions, preferentially adsorbed on the surface. The fact that acid does not reverse the charge on silica indicates that soil acidity cannot be ascribed to the silica acting as an acid in stoichiometric proportions, but is rather due to the preferential adsorption of H ions by the hydrated substances. The colloid behavior of stearic acid illustrates the importance of hydration.

B. C. A.

Theory of the spontaneous division of drops of microscopic size. N. VON RASCHESKY. *Z. Physik* **46**, 568-93(1927).—The method of Gibbs has been employed in the investigation of the stability of drops of microscopic size. It is shown that, if the velocity of change of the size and constitution of the drops is small due to chem. transformations, and if effects due to elec. charges are neglected, the drops are absolutely stable for a pos. surface tension in the absence of capillary-active adsorbents. Under the same condition but with neg. surface tension, the drops are always labile and tend to disperse. In the presence of dissolved capillary-active adsorbents and with a pos. surface tension the drops are stable. A no. of other related problems are discussed.

B. C. A.

The Brownian displacements and thermal diffusion of grains suspended in a non-uniform fluid. S. CHAPMAN. *Proc. Roy. Soc. (London)* **A119**, 34-54(1928).—The Einstein derivation of the distribution function for the displacement of grains at any time after $t = 0$ in a uniform stationary liquid has been generalized for non-uniform fluids. Non-uniformity may be due to temp., concn., or any other factor affecting the coeff. of diffusion. An undetd. const. is included which is assumed to be zero for Brownian grains large compared to the mean free path of the mols. of the fluid. It is possible to produce a uniform distribution of grains by having a vertical temp. gradient opposing the gravitational effect since grains tend to go from warm to cold regions. This effect is more pronounced with liquids than with gases as the medium. Cases are cited where the densities of grains and medium are the same or different. R. H. L.

The molecular displacements in diffusing gas-mixtures. S. CHAPMAN. *Proc. Roy. Soc. (London)* **A119**, 55-60(1928).—The more sp case of mol. displacement in a gaseous medium (cf. preceding abstr.) is studied. It is of interest from the standpoint of the kinetic theory of gases. The treatment is considered both for uniform temp. and a temp. gradient. The effect for mols. as rigid spheres and of different sizes is also shown.

RAYMOND H. LAMBERT

Relative rate of diffusion of the electrolytes in the charged gels. (MLLE.) F. CHOUCKOUN. *Compt. rend.* **187**, 296-7(1928); cf. *C. A.* **22**, 3084.—C., continuing work which showed that the rate of diffusion through a membrane was modified only if its charge is the same as the less mobile ions, establishes quant. the diffusion coeff. of ferrocyanide through neutral and alk. gelatin gels. The diffusion of the ferrocyanide is detd. by its adsorption of a beam of light of uniform intensity passed through the gel. The ratio between the 2 diffusion coeffs. at 28° is 1/2.5. The rate is the same in neutral and alk. soln. The diffusion coeff. is 0.47×10^{-8} c. g. s. units at 28°. D. H. POWERS

Determination of vapor pressure of saturated aqueous solutions. F. POHLE. *Mitt. Kali-Forschungs-Anst.* **1927**, 33-43.—Detns. were made of the satn. pressure of satd. solns. of Mg, Na and K chlorides and sulfates, and of various mixts. of the salts. The b. ps. were also detd.

B. C. A.

The state of ionization of solutions of hydrogen sulfide. MAURICE AUMERAS. *Compt. rend.* **186**, 1724-6(1928).—An expression is given for the law of soly. of CdS in HCl at a temp. of 16°. The soly. product const. of CdS is 3.6×10^{-29} and the values 0.59×10^{-16} and 0.37×10^{-16} are given for the second dissoen. consts. of H₂S. Values of the first const. of dissoen. of H₂S, given by Walker and Conrad, are 5.7×10^{-8} and 9.1×10^{-8} .

H. R. MOORE

The effect of salts on weak electrolytes. I. Dissociation of weak electrolytes in the presence of salts. HENRY S. SIMMS. Rockefeller Inst. Medical Research. *J. Phys. Chem.* **32**, 1121-41(1928); cf. *C. A.* **20**, 2774.—The term index is introduced to signify the negative logarithm of a quantity. Thus $-\log X = P_X = \text{index of } X$. Titration data of 0.01 M solns. of acetic, oxalic, malonic, succinic, azelaic, citric and aspartic acids, succinimide, aminoethanol and glycine were obtained, in the absence of salt, in the presence of 2 concns. of NaCl and in the presence of 2 concns. of MgCl₂. (K₂SO₄ and MgSO₄ were also used with malonic acid.) From each observation a dissoen. index value (P_k') was calcd. and plotted against the sq. root of the ionic strength ($\sqrt{\mu}$).

The slopes of these curves show the extent of the agreement of the activity of the ions with the activities predicted by the Debye-Hückel equation. Singly charged anions from univalent or bivalent acids obey the Debye-Hückel equation in the presence of either NaCl or MgCl₂, or the salt of the weak acid, but not with K₂SO₄ or MgSO₄. Multivalent anions in the presence of NaCl obey a modified form of this equation which includes a correction for the distance between the charges. Multivalent anions behave anomalously with MgCl₂. This effect is much greater for oxalic, malonic and citric acids than for succinic, azelaic and sebacic acids. Sulfate ions produce an effect on both mono- and dianions which is opposite to the effect of Mg ions. Cations from amines or amino acids do not obey the Debye-Hückel equation but show a deviation with both NaCl and MgCl₂ which varies with the substance. P_{K_1}' of glycine and P_{K_1}' of aspartic acid are anomalous in the presence of MgCl₂ but normal with NaCl. Isoelectric points drop with increase in ionic strength. E. R. SMITH

The transport number of the cation in aqueous solutions of nickel salicylate. FREDERICK E. JONES AND C. R. BURY. Univ. College of Wales. *J. Phys. Chem.* **32**, 1272-5(1928).—Transference nos. in Ni salicylate solns. at 25° were detd. throughout the range 0.02 to 0.2 (the limit of soly.) mols. per 1000 g. of H₂O. The cation transference no. varied from 0.573 at 0.2046 molal to 0.612 at 0.0192 molal. The results show that Ni salicylate ionizes mainly in a normal manner but also suggest the presence of small quantities of a complex acid form. E. R. SMITH

Kinetics of the combination of hydrogen and oxygen. C. N. HINSHELWOOD AND H. W. THOMPSON. *Proc. Roy. Soc. (London)* **A118**, 170-83(1928).—The whole course of the gaseous reaction between H and O has been examd. by a static method at const. temp. and vol. over a range of temp. from the region where the reaction is undoubtedly a heterogeneous surface reaction to near the point at which the combination ceases to be isothermal and passes into explosion. The app. was essentially the same as that previously described (cf. *C. A.* **18**, 1444). At temps. below or not much above 500°, the reaction is approx. of the first order, in agreement with the results of Bone and Wheeler (*Phil. Trans.* **206A**, 1(1906)). It is greatly accelerated by the presence of powd. silica in the bulb, and somewhat retarded by the presence of steam. From about 520° to 530° a reaction comes into prominence which is quite different from the low-temp. reaction. A definite order cannot be assigned to the reaction, for the apparent order tends to increase with pressure and with rise of temp. but on the av., the influence of pressure between 540° and 560° is roughly characteristic of a fourth-order reaction. It is strongly autocatalyzed by steam and has a high temp. coeff. At high temps. the normal pos. catalytic effect of the walls of the reaction chamber is replaced by a neg. effect, which may be due to the catalytic destruction of an autocatalyst for the principal reaction (cf. Egerton and Gates, *C. A.* **21**, 2555), or to the interruption of "reaction-chains" (cf. Christiansen, *C. A.* **18**, 1419), or to a combination of both causes. It is suggested that the high-order reaction is the true gas reaction between H and O. B. C. A.

Decoloration velocity of potassium permanganate by oxalic acid, and its influence by substances present in the solution. M. BOBELSKY AND D. KAPLAN. Hebräische Univ. Jerusalem. *Z. anorg. allgem. Chem.* **172**, 196-212(1928).—The appearance of the induction and its behavior are discussed. The induction has been connected with the elec. state of the soln. The decompn. of the MnO₄ ion has been examd. The influence of various compds. in the solns. has been investigated. In dil. soln. neutral ions have very little effect. In concd. soln. they play an important role. Zn, Cd, Al and Cl ions accelerate the reaction very markedly. Fe⁺⁺, Fe⁺⁺⁺, Ag, Mn⁺⁺, Hg⁺⁺, Pb⁺⁺, Br and I ions, As₂O₃ and SO₂ have a decided effect: their relative importances are tabulated. It is possible quantitatively to titrate the above ions by measuring the influence undergone in the decoloration of the MnO₄ ions. A. I. HENNE

The inversion point of second order. WITOLD JAZYNA. Tech. Inst. Leningrad. *Z. Physik* **49**, 270-8(1928).—The inversion point of second order is given by $X = (\partial\mu/\partial p)_T, J$, where μ (the first order inversion point) is defined by $(\partial t/\partial p)_J$. J is energy content. A change of μ with pressure at const. temp. has been established for air, O₂ and CO₂. The existence of max. and min. values of μ for air and H₂ proves the existence of a second order inversion point where $(\partial\mu/\partial p)_T = 0$. Variations of expansion coeffs. $(\partial\alpha/\partial p)_T$ in the neighborhood of the second-order inversion are also expld. criteria. H. R. MOORE

Reactivity of iodine in organic solvents. I. FRITZ FRIGL AND ERWIN CHARGAV. Univ. Vienna. *Monatsh.* **49**, 417-28(1928).—The brown soln. of I in Et₂O, EtOH, dioxan, cyclohexanol and cyclohexane reacts with Ag saccharin with quant. formation of AgI; the violet soln. of I in CHCl₃ and C₆H₆ also reacts quant., while that in CS₂,

CCl_4 and petr. ether forms very little AgI . Br in CS_2 and Et_2O behaves like I. Hg succinimide and I in CS_2 and Et_2O behave like Ag saccharin. C. J. WEST

The reduction of silver sulfide by means of carbon. N. PARRAVANO AND G. MALQUORI. Univ. Roma. *Atti accad. Lincei* [6], 7, 367-9 (1928).—The method was that already used for MoS_3 (cf. C. A. 22, 2091). A current of N was passed over a mixt. of Ag_2S and graphite at 1015° and at 1050° in an elec. furnace, vapors of S and CS_2 were condensed, and the quantity of each was detd. The values of S_2/CS_2 were 0.113 at 1015° and 0.188 at 1050° , from which it was calcd. that p_{CS_2} was 35.6 mm. of Hg at 1015° and 39.6 mm. of Hg at 1050° . These values agree well with those calcd. from the equation: $p_{\text{S}_2}/p_{\text{CS}_2} = \text{const.}$ C. C. DAVIS

The dissociation of chromium azide. G. VALENSI. *Compt. rend.* 187, 293-6 (1928).— CrN is prepd. by heating pyrophoric Cr in N_2 at 800° . The dissocn. is detd. by measuring the N_2 after allowing about 10 hrs. for equil., tracing the curves for increasing and decreasing temps. The analogy to the Pd- H_2 network is striking. Each isotherm has a plateau of decreasing amplitude with increasing temp. Solns. of CrN in Cr may be formed. D. H. POWERS

The system calcium oxide, silica and water. JOHN R. BAYLIS. *J. Phys. Chem.* 32, 1236-62 (1928).—When lime is added to a suspension of silica gel in water there appears to be formed a compd. of CaO and SiO_2 corresponding to the hydrated $\text{CaO} \cdot \text{SiO}_2$. The addn. of more CaO to the suspension results in the adsorption of $\text{Ca}(\text{OH})_2$ to an extent equal to 30-45% of the lime chemically united with the silica. These conclusions are drawn from expts. in which the p_{H} value of the soln. and the total alky. toward H_2SO_4 were detd. after each addn. of lime to the suspended gel. The points of min. p_{H} and alky. correspond approx. to monocalcium silicate. Further addn. of CaO causes these values to increase rapidly up to those at the satn. point of $\text{Ca}(\text{OH})_2$. No evidence of compds. with a higher Ca content is shown. That the equil. between the soln. of $\text{Ca}(\text{OH})_2$ and the adsorbed $\text{Ca}(\text{OH})_2$ is reversible is shown by the fact that it is approx. the same whether it is estd. by the addn. or the extn. of $\text{Ca}(\text{OH})_2$. The same type of reversible adsorption is shown when lime is added to a suspension of the diatomaceous earth "Celite." It is possible that this condition of surface equil. materially retards the rate of hydrolysis of some of the compds. in concrete submerged in water. According to B. the assumption of Bogue (C. A. 22, 1452) that dissocn. of the Ca silicates causes the variable p_{H} or alkali concn. as the Ca is leached out is not correct. H. F. J.

Contribution to the knowledge of the precipitation of salt from sea water. The polytherms of the equilibrium solubilities in the potassium chloride region and of the points Y and Z. GEORG LEIMBACH. *Mitt. Kalb-Forschungsanstalt* 1925, 11-48; *Chem. Zentr.* 1927, I, 414; cf. C. A. 20, 1970.—L. extends to 103° the values detd. by Feit-Przileylasch (*Kali* 3, 393 (1909)) for the soly. of KCl and NaCl in MgCl_2 solns. of various concns. at 15.40° and 90° , and he interpolates the figures at 83° . F.-P. considers only the influence of MgCl_2 on the soly. of KCl and NaCl at various temps. L. detcs. the line P-R, where MgSO_4 also begins to crystallize as Langbeinite. The line P-R is detd. exptly. at 83° , 95° and 105° . The point Y_{83} shows an appreciable deviation from the data obtained by synthesis (Serowysch). Approx. values of Y_{93} and Y_{105} are also detd. L. confirms the value of Z. (theoretical limit to which the mother liquor should be evapd. to recover MgCl_2) at 25.55° and 83° and detcs. it at 95° and 105° . A. L. HENNE

The heterogeneous equilibrium between metallic chlorides and hydrogen sulfide, or metallic sulfides and hydrogen chloride at higher temperatures. KARL JELLINEK AND GEORG VON PODJASKI. *Techn. Hochschule, Danzig. Z. anorg. allgem. Chem.* 171, 261-70 (1928).—The equilibria for the reactions between H_2S and CdCl_2 , MnCl_2 and AgCl , resp., were detd. at several temps. In the formation of CdS , 76.5% of the total amt. of HCl is obtained at 352° . Only 13.1% of the HCl is obtained at 232° . The extent of conversion is less for the other sulfides studied. Equil. data are shown graphically. The heat of reaction (endothermic) for each metallic chloride with H_2S is calcd., viz., CdCl_2 —18,230 cal.; MnCl_2 —20,030 cal.; 2AgCl —16,790 cal. A. J. C.

The heterogeneous equilibrium for the reaction, $\text{CdBr}_2 + \text{H}_2\text{S} \rightleftharpoons \text{CdS} + 2\text{HBr}$, at higher temperatures. KARL JELLINEK AND LEON ZUCKER. *Techn. Hochschule, Danzig. Z. anorg. allgem. Chem.* 171, 271-4 (1928).—The technic was the same as that in a previous study (preceding abstract). The reaction is endothermic (—28,030 cal.), 89.2% of the total amt. of HBr was obtained at 502° , 40% at 446° , 16.4% at 387° and 4.4% at 299° (extrapolated to 0 rate of flow of gases). A. J. CURRIER

Equilibrium of molten sulfides and silicates. WILHELM JANDER AND KURT ROTHSCHILD. Würzburg Univ. *Z. anorg. allgem. Chem.* 172, 129-46 (1928).—The systems: $\text{Na}_2\text{SiO}_3 + \text{PbS}$; $\text{PbSiO}_3 + \text{FeS}$; $\text{Cu}_2\text{SiO}_3 + \text{FeS}$; $\text{NiSiO}_3 + \text{FeS}$; PbSiO_3 ,

+ Cu_2S ; Cu_2SiO_3 + NiS and NiSiO_3 + PbS have been experimentally investigated in the molten state. The simple mass-action law is not available for these systems. An approximation $K = C + aC^2$, derived from the Lorenz modification of the mass-action law, has been used and gave satisfactorily checking consts. In nearly every case, the reaction const. of a system could be computed from the reaction consts. of 2 other systems. At high temp., the affinity of the various metals for O and S undergoes important modifications.

Catalytic hydrogenation. E. J. LUSH. *Notiz. chim.-ind.* 3, 361, 363, 365, 367, 369(1928); cf. *C. A.* 21, 2390, 3475.—A review and description, with illustrations and diagrams of the continuous hydrogenation of oil, catalysts and their oxidation, the recovery of inactive catalyst, the use of catalytic "cages," hydrogenation app. and equipment and hydrogenated oils. Eight references are included. C. C. DAVIS

Catalysis. H. E. DALE. *Pharm. J.* 120, 92(1928).—A concise review of catalysis illustrating by selected examples its theoretical and practical importance. S. W.

A new interference method of measuring the surface area of film catalysts. I. The theory. F. HURN CONSTABLE. *Proc. Roy. Soc. (London)* A119, 196-201(1928).—By adsorption methods only a fraction of the true surface of catalysts can be measured. Direct spectrophotometric measurements of the intensity and wave length of the light reflected from oxidized surfaces of Fe, Ni and Cu leave no doubt that interference is the main cause of production of the color sequences. The color of the oxide film det. its thickness when the order of the color and the n of the film is known. A general method is developed mathematically by means of which the surface area of films can be evaluated. II. **Nickel—method of preparation of the film, an apparatus for activation, and study of the surface area.** *Ibid* 202-13.—China-clay rods were first coated with a continuous film of graphite-oleic acid paste and the oleic acid was removed by elec. heating. The graphite-coated rods were covered with a measured amt of Ni film by electrolysis from Ni solns. at a known rate. An app. was devised to move the rod in such a way as to insure a uniform deposit. The change of elec. resistance and of refractivity of the film when subjected to oxidation and reduction was measured. The app. was of special design. The surface area was calcd. from the refraction measurements. The max. area of the film per unit mass of Ni was measured for various temps. of activation by alternate oxidation and reduction. The max. increase in surface area on activation was found to be about 5 times. Reduction at 563° decreased this to 1.3 times.

R. L. DODGE

Catalysts used in the synthesis of higher hydrocarbons from water gas. A. ERDELY AND A. W. NASH. *J. Soc. Chem. Ind.* 47, No. 32, 219-23T(1928).—A continuation of Elvin's expts. (*C. A.* 22, 3130). From the expts. with different, unpromoted catalysts at 285° , and with a gas mixt. contg. equal parts of CO and H_2 , a Co-Cu-ZnO catalyst appears to be most suitable. After the initial period its activity was very const., causing a contraction of about 50% for several days continuous operation. A Co-Cu- Al_2O_3 catalyst gave nearly as satisfactory performance, although less oil and more H_2O was formed in its presence. The oil yield was highest with an unpromoted Co-Cu catalyst, although the activity of this catalyst decreased most rapidly. A Co-Cu- CeO_2 catalyst gave the lowest yield of H_2O and a fair yield of oil, but although the initial activity of this catalyst was the greatest, its activity decreased about as rapidly as that of the Co-Cu. Catalysts supported on silica gel were as active as the Co-Cu-Mn catalyst only in one instance. In this connection, the importance of the relative proportions of catalyst to support was shown. The optimum temp. for the formation of liquid hydrocarbons was found to be $280-290^\circ$ for the Co-Cu- Al_2O_3 catalyst. Above 290° CO_2 and CH_4 are the chief products, and below 230° no reaction was observed. An excess of H_2 in the initial gas mixt. increased the H_2O formation, while an excess of CO rapidly decreased the activity of the catalyst. The gas velocity exerts a marked influence on the yield of products. The optimum space velocity for the Co-Cu-ZnO catalyst was about 120 vols. of gas per hr. per unit vol. of catalyst.

J. H. PERRY

The thermal decomposition of ammonia on tungsten, molybdenum and nickel. I. C. H. KUNSMAN. *J. Am. Chem. Soc.* 50, 2100-13(1928).—The rate of decompn. of NH_3 on W, Mo and Ni filaments was measured at 900° to 1300° by observing the rate of pressure increase in a closed glass system contg. the electrically heated filaments. The order of the reaction was detd. by the usual method and found to be an apparent zero order. Diln. of the NH_3 and N had relatively little effect on the decompn. rate. H diln., however, showed a large retarding effect, greatest at the lowest temps. Preliminary heating of the filaments to 1600° caused a marked decrease in activity. Thoriated W wire showed no greater activity than W. The value of the E in Arrhenius

equation as calcd. from the data decreased with increase in temp. being about 45,000 cal. at about 900°. The change in E with increase in temp. is no doubt due to a change of the surface of the wire.

R. L. DODGE

Catalytic chlorination of acetic acid to chloroacetic acid. H. BRÜCKNER. *Z. angew. Chem.* **41**, 226-9(1928); cf. *C. A.* **21**, 3345.—The velocity of chlorination of acetic acid in presence of I, P or S increases with the amt. of catalyst used, but not in direct proportion. Of the 3 catalysts I gives the best results, but more effective chlorination is obtained with mixts. of 3 catalysts, chlorination in presence of a mixt. of I, P and PCl_5 being more rapid than in presence of S, PCl_5 and P. Binary mixts. of catalysts are less effective than the ternary mixts. Ac_2O is chlorinated in the absence of a catalyst, and in the chlorination of AcOH the presence of chloroacetyl chloride and the mixed anhydride of acetic and chloroacetic acid has been established. The suggested mechanism of the chlorination is represented by a series of equations. S and P appear to act by accelerating the formation of acetyl chloride, and I by the dispersion of the Cl through the reaction mixt. in consequence of the formation of I chloride and I trichloride.

B. C. A.

Mechanism of 2,4-dinitrophenol formation from benzene and nitric acid in presence of mercury salts as catalysts. A. I. ZAKHAROV. *J. Chem. Ind. (Moscow)* **4**, 960-4 (1927); **5**, 26-7(1928).—To find the course of the reaction it is necessary to det. its speed at arbitrary time intervals and thus find the order to which the reaction belongs. A soln. of 10 g. C_6H_6 , 50 cc. HNO_3 sp. gr. 1.36 and 1 g. of the Hg catalyst was kept at 15° for 432 hrs., being agitated every 1-2 hrs. The concn. of HNO_3 in this soln. was detd. at definite time intervals and $K^2 = (1/t) \cdot x/(a-x)a$ and $K^3 = (1/t) \times (2a-x)/(a-x)^2$ have been calcd. The figures obtained for K (const. of speed) gradually decreased, which indicated the decrease of speed with the time. To det. the order (class) of the reaction van't Hoff's method has also been applied and gave the same neg. result; complicated combinations between the components are thus indicated. However, while it has been established that in this freshly prepd. soln. in which $\text{Hg}(\text{NO}_3)_2$ served as catalyzer, the course of the reaction is complicated, in solns. in which the catalyzer has already oxidized C_6H_6 , the course of the reaction is simplified considerably, in the latter case the speed, after some initial fluctuations, becomes const. and, from the figures obtained, indicates a reaction of the second order. The complications which take place at the outset of these reactions, particularly when using freshly prepd. solns., can be explained by the peculiarity of the catalyzer: in order to become active the catalyzer requires a certain amt. of acid, which thereby ceases to take part in the main reaction and causes complications. Expts. were instituted to det. whether each of the 2 intermediates PhOHgNO_3 and $\text{O}_2\text{NC}_6\text{H}_4\text{OH}$ is actually formed in the reaction. It was expected that by operating with very dil. HNO_3 and at low temp. the passage from one intermediate into another would become slow, which would permit detecting the presence of either of them by means of appropriate sensitive reagents. All attempts in this direction failed. If the Hg salt is the transmitter of O, then an increase in the strength of the acid would be increasing only the process of formation of mono- and polyphenols, which is in contradiction with exptl. data. Expts. show that the nature of the final products of reaction depend on the concn. of the acid. If the acid is dil. its activity is directed towards oxidation and the final product consists of nitrophenols; if, on the contrary, the concn. is comparatively great, its oxidizing power is decreased and the course of the reaction is the resultant of 2 factors, namely the nitrating influence of HNO_3 and the nitrating influence of the catalyzer, and the final product of the reaction is nitrobenzene. The role of the catalyzer consists in nitrating the original C_6H_6 . It is known that the oxidation of C_6H_6 is the greater the more nitro groups it contains; but the process of oxidation depends on the strength of HNO_3 used. As a whole, the process of formation of nitrophenols takes place through the formation of unstable Hg nitrobenzene compds as intermediates, and this explains the fact that a certain amt. of nitrobenzene always accompanies nitrophenols in this reaction. It is thus evident that used solns. must be in a more active state than freshly prepd. solns., since in the former the catalyzer is contained in another form which is the real catalyzer of the reaction, whereas in freshly prepd. solns. the active form is at first absent and some time is required for its formation. Expts. show that freshly prepd. solns. of 59-60% acidity and 30% catalyzer content give at 35-40° an av. dinitrophenol yield not above 40%; when these solns. are used for the second time under the same conditions the yield of dinitrophenol is increased to 50-55% and, after using them 3, 4, etc., times, the yields reach 65, 75 and 80%.

BERNARD NELSON

Determination of heat of combustion with Féry's calorimeter. F. KARAS. *Chem. Obzor* **1**, 121-5(1926).—The max. deviation of results obtained with Féry's and the

Berthelot-Mahler-Kroeker calorimeters is 1.21%; Féry's method occupies half the time of the latter method. Errors may arise from the radiation from incandescence lamps; day- and night-values may differ by 2%. B. C. A.

Heat conductivity of metals as factor in heat transfer. ROBERT WORTHINGTON. International Nickel Co., New York. *Chem. Met. Eng.* 35, 481-2(1928).—Argument that the controlling factor in heat transfer is the existence of various types of surface films and not thermal cond. of metals. G. B. TAYLOR

Heat transmission of liquids flowing through tubes. L. SCHILLER AND TH. BUBACH. *Z. Ver. deut. Ing.* 72, 1195-6(1928).—See C. A. 22, 3076. H. G.

Difference $c_p - c_v$. A. BACHINSKII. *Z. Physik* 45, 892-4(1927).—The sp. heats of a gas for which the equation of state $p v = RT$ is assumed valid are related to the gas const. by the equation $c_p - c_v + p(dc_p/dp)_v - v(dc_v/dv)_p = AR$, where A is a const. When c_p and c_v are functions of temp. only, the equation of state becomes $T = \alpha p v + \beta p + \gamma v + \delta$, where α, β, γ and δ are arbitrary const., and $c_p - c_v = AT/(\alpha T + \beta \gamma - \alpha \delta)$. By choosing values so that $\alpha \delta = \beta \gamma$, the following relationships are derived: $c_p = c_v = A/\alpha$ and $T/\alpha = [p + (\gamma/\alpha)]v + (\beta/\alpha)$. The latter expression is identical in form with the equation of state observed by Tammann for a series of liquids at 0-50° and at pressures from 10^3 to 3×10^3 atm., $CT = (p + K)(a - b)$; by identifying α with $1/C$, $c_p + c_v$ should have a const. value of AC . It is shown from Tammann's data that this is roughly true. By extending this analysis a soln. has been obtained for the equation of state for which $c_p - c_v$ has a const. value AR . B. C. A.

Rotational and vibrational specific heat of a diatomic gas, the molecules of which have a doublet P normal state. ENOS E. WITMER. Harvard Univ. *Phys. Rev.* 29, 918(1927).—A description is given of the differences between the sp. heat-temp. curve of a diatomic gas in which the mols. have a single electronic state as the normal level and the curve when the mols. have a double level. W. W. STIFLER

Simplified formulas for specific heats of gases and solids, especially of explosion products. NORUJI YAMAGA. *Proc. Imperial Acad. (Japan)* 4, 102-5(1928).—Following Eucken, Y. has deduced formulas for the sp. hts. between 3000° and 4000° for each of the commonly occurring gases and for a diatomic gas. CHARLES F. MUNROE

Classical thermodynamics and the new problems of chemical dynamics. HORACE DAMIANOVICH. Univ. Buenos Aires. *Anales soc. cient. Argentina* 105, 225-71(1928); cf. *Ibid* 84, 105(1917); *Revista del Centro Estudiantes de Ingeniería* No. 180 (1917); *Revista de Filosofía* III, 227(1917).—Classical thermodynamics deals only with systems in equil. and fails to yield any theoretical deductions concerning the mechanism by which a new equil. is reached. D. reviews the views of Duhem, Hatanson, Helmholtz, van't Hoff, Nernst Berthelot, Ostwald and Marcelin on this subject. In D.'s previous work he has developed an equation for the velocity of reactions by introducing the concept of acceleration. Combining this with Marcelin's equation, D. derives an equation in which the velocity is connected with the affinities. Using the equation he classifies physicochem. transformations in the following way: First category (A) coeff. K depends on temp.; (a) unimol. chem. reactions, irreversible, reversible and simultaneous; (b) soln., simple diffusion, evapn., sublimation and dehydration of crystals; (B) coeff. K does not vary with temp.; (a) radioactive transformations considered as unimol.; (b) unimol. photochem. transformations. Second category: the variables of evolution depend on the concn. at every instant; (A) transformations in which no catalyst is used: (B) catalytic transformations; simple catalysts, autocatalysis, complex catalysis (diastases, etc.) No concrete examples are given. A. F.

The van der Waals-Clausius equation leading to the necessary integrating factors of thermodynamics as a function of two variables. A. PRESS. *Z. Physik* 49, 306-10(1928).—The general integrating factor $\mu = T^{-1}$ of thermodynamics usually suffices for all conditions of integrated equations of the van der Waals type, but a rigorous derivation of an equation of state requires that μ be taken as a function of 2 variables, i. e., $\mu = f(v, t)$. The equation of state is simplified when $\partial U/\partial T$ is independent of temp. H. R. MOORE

Chemical constants in the new quantum statistics. G. E. GIBSON AND W. HETTLER. Univ. Göttingen. *Z. Physik* 49, 465-72(1928).—The application of the new quantum statistics to the dissocn. of a diatomic mol. composed of like atoms gives the equil. equation, $\ln K = D/kT + 3/2 \ln (\pi m k T/h^2) - \ln (8 \pi^3 J/h^2) + \ln (1 - e^{-h\nu/kT}) + \ln 2 + 2 \ln g_s$, where ν = vibrational frequency of mol. in the normal state; D = heat of dissocn. of the mol., J = moment of inertia, and g_s the statistical weight of the normal state of the atom. Substitution of the spectral values for D, J, ν and g_s gives values for the equil. const. in close agreement with Starck and Bodenstein's exptl. values. W. West

The quantum theory of molecule formation. HANS LESSHEIM. *Naturwissenschaften* 16, 576(1928); cf. *C. A.* 22, 1531.—London's solution (*C. A.* 22, 1531) of the symmetry character of the center of gravity function is only 1 out of 3 possible solutions of the problem of mol. formation. By using another one, which neglects the interaction of orbit impulse and electron moment, a better picture of the chem. conduct of elements can be obtained. In particular the character of the noble gases and the difference between pos. and neg. elements follows more clearly. B. J. C. v. d. H.

Electrification produced by friction between gases and solid surfaces. I. M. A. SCHIRMANN. *Z. Physik* 46, 209-36(1927).—Two types of electrification by friction have been identified during the operation of Hg vapor diffusion pumps: the first, which takes place at low rates of vapor flow, is due to friction between Hg droplets and glass surfaces; the second takes place at flow rates of the order of 10^4 cm./sec. and is due to friction between the vapor and glass surfaces. Confirmatory expts. have been carried out by releasing compressed N from a highly insulated metal bomb in which the bomb attains a potential of several hundred volts. B. C. A.

Electrification in gases due to friction with solid surfaces. E. PERUCCA. *Z. Physik* 46, 747-52(1928).—Expts. are described in which electrification results from the friction between a stream of Hg vapor and an Fe electrode; the conditions were chosen so that the vapor was free from droplets. It is therefore concluded that droplets play no part in the observed phenomenon. B. C. A.

Effect of temperature on polarization capacity and resistance for gold and platinum electrodes in different concentrations of sulfuric acid and at different audible frequencies. E. F. ZIMMERMAN. Cornell Univ. *Phys. Rev.* 29, 913-4(1927).—For Pt electrodes in 12.7% soln. of H_2SO_4 , the temp. coeff. of polarization capacity is pos. between 0° and 90° , decreasing in value at higher temps. For Au electrodes the value is about 0.1 that for Pt and increases at higher temps. Cell resistance with Pt electrodes decreases at higher temps. but the reverse is true of Au. For both the temp. coeff. of capacity decreases with increase in frequency between 650 and 3900 cycles. W. W. S.

The influence of movement of electrolyte upon the steadiness of the potential of the oxygen electrode. H. V. TARTAR AND VICTOR E. WILLMAN. Univ. of Washington. *J. Phys. Chem.* 32, 1171-7(1928).—The effect of the rate of flow of electrolyte on the potential of the O electrode has been studied and it has been shown that the potential is quite steady for a given electrode in a given electrolyte if the rate of flow remains unchanged. Under the same conditions of flow bright Pt electrodes seem to give fairly reproducible potential values within a few millivolts. The behavior of the O electrode may be more easily interpreted by the assumption of the formation of a sol. substance, possibly H_2O_2 , than by the so-called insol. Pt oxide theory. E. R. SMITH

The tarnishing of palladium by heating in air and by anodic polarization. G. TAMMANN AND J. SCHNEIDER. Univ. Göttingen. *Z. anorg. allgem. Chem.* 171, 367-71(1928).—Pd foil after heating in air to $400-750^\circ$ becomes vari-colored and at higher temps. resumes its original appearance. Heated for an hour, in air at 400° , it changes to red (I order). At 500° , 550° , 600° , 680° and 750° the color varies from orange (I) to yellowish green (II). The measurements showed that Pd tarnishes in air similarly to other metals according to the log. law. Data are plotted as follows. logs. of time, in min. as abscissas and air film thickness in μ equiv. to the colors, as ordinates. A straight line is obtained for each temp. which cuts the abscissa at the log. of time. By action of anodic O_2 , films of greater thickness are formed (from brownish yellow I to V order). A Pd foil served as anode in 1.6 N H_2SO_4 between two Pt cathodes of the same size. The film was thicker, by 400μ , at the edges than in the center of the foil. Values of μ /milliamp., for varying c. ds. (after 2 min.) show that not all evolved O_2 goes into the oxide layer. Since they decrease with increasing c. d. PdO only could be formed on oxidation in air for according to L. Wohler, PdO_2 and Pd_2O_3 are no longer stable above 200° . The film formed by electrolysis is probably a hydrated oxide, which changes either in compn. or form. A film of 352μ , equiv. to air film thickness formed at higher temp. in air, disappears in O_2 gas at 20° within 20 min. The same holds true for the electrolytic film of equal thickness. Pd black could not be detected in either case. At approx. 700μ the electrolytic film first disappeared in O_2 gas after 50 min. at 20° and left a visible coating of Pd black. A. J. CURRIER

Critical potentials of copper. RICHARD HAMER AND SURAIN SINGH. Univ. of Pittsburgh. *Phys. Rev.* 29, 901-2(1927).—The method consisted in searching for repeatedly recurring breaks in the current-potential curves when a Cu cylinder and insulated central Cu rod were heated to approx. 700° in a highly evacuated quartz tube. This preliminary report up to 30 v. indicates critical potentials at 3.3, 7.9, 14.2, 19.5 and 25.3 v. W. W. STIFLER

Polarity and piezoelectric excitation. A. HETTICH AND A. SCHLEEDÉ. *Z. Physik* **46**, 147-8(1927).—Arguments are advanced claiming to invalidate the suggestion of Mark and Weissenberg (*Z. Krist.* **65**, 435(1927); cf. *C. A.* **22**, 1507) that the piezoelec. excitation of pentaerythritol affords evidence of polarity in the direction of the principal axis. B. C. A.

Conductivity of powdered salts. JEAN CICHOCI. *Compt. rend.* **187**, 287-9 (1928).—C. verifies the hypothesis of Peczkalski (*C. A.* **22**, 2870) that the cond. of powd. salts is due not only to the cond. of the solid particles but also to the cond. of the salt vapors. BaCl_2 is put in a Cu tube (1 cm. \times 12 cm.) contg. a concentric Cu wire (0.7 mm. diam.). The tube is put in a flask and kept under 1 mm. pressure. The wire and tube serve as electrodes and the temp. is measured by a thermocouple. Detns. are made of the external temp. (*t*), the intensity of the current (*b*), the potential drop along the wire (*v*), the intensity of the anodic current (*i*) and the time of flow of current (*a*). From *b* and *v* the resistance of the wire is deduced. Curves are given plotting *a* against *i*. Results confirm Ohm's law. The major part of the salt is below the temp. of the emission of ions but its cond. is of the order of the cond. observed at the temp. of the heated wire. This can only be explained by the presence of salt vapors uncondensed in the cold part of the tube. The cond. is also partly due to the dispersion of the Cu in the salt when the wire is used as the anode. D. H. POWERS

Influence of gelatin on the potential and discharge potential of zinc in zinc sulfate solution. E. RABALD. *Z. Elektrochem.* **33**, 532(1927).—A reply to Izgaruishev and Titov (*C. A.* **21**, 3163) B. C. A.

The local element theory of metal solution. A. THIEL AND J. ECKEL'S. *Sitzber. Ges. Beförderung gesamten Naturwissenschaften zu Marburg* **61** (Sept., 1926); *Chem. Zentr.* **1927**, 1, 857 —Preliminary paper. To gain insight into the problem of the metal soln. in acids, it is essential to follow a well-defined and clear exptl. method. This precludes the use of alloys or of metals pptd. on an active surface. T. and L. use 2 identical plates of metal, one of pure Zn, and the other of the metal to be investigated. The plates are connected through an ammeter which indicates the rate of liberation of H by the second metal in relation to that of the Zn during and after combination. Sp. expts. showed that the evolution of H at the second metal follows Faraday's law, so that measuring the current intensity of the metal combination affords the simplest way of detg. accurately the catalytic or activating effect of foreign metals on the Zn soln. in acids. The fraction given off by Zn is the difference between the total rate of formation and that calcd. for the second metal. The overvoltage at the metal liberating H is detd. by measuring the potential at the electrode, in the absence of air. This should be equal to the potential observed at the second metal (compared with H_2 in the same electrolyte, without stirring). The rate given by the combination of the 2 metals falls always short of sum of the rate of soln. of Zn alone, and that calcd. from the potential of the second metal. No satisfactory explanation of the rate variations has been found as yet. The same observations were made in the soln. of Al in NaOH. A. L. HENNE

Resistance change of single crystals of bismuth in a longitudinal magnetic field. G. W. SCHNEIDER. *Phys. Rev.* [ii], **31**, 251-9(1928).—The resistance change as a function of the orientation of the vertical crystallographic axis was investigated. B. C. A.

Measurements of the disturbance caused by a magnetic field on the superconductivity of thallium. W. TUIJN. *Verslag Akad. Wetenschappen Amsterdam* **37**, 476-80 (1928).—A TI resistance, maintained at low temp., is subjected to the variations of a magnetic field (transverse to the current flow) (cf. *C. A.* **21**, 3305). If the temps. in $^\circ\text{K}$. are: 2.47, 2.21, 2.20, 2.19, 1.85 and 1.83, the values of $H(0.5)$ in gauss are: 0, 31, 32, 34, 65 and 67, resp. A. L. HENNE

The paramagnetism of iron in the ferricyanide of potassium. MILLE. PAULE COLLET AND FRANCIS BIRCH. *Compt. rend.* **187**, 35-6(1928).—Measurements by the method of attraction in a non-uniform field were made on $\text{K}_3\text{Fe}(\text{CN})_6$ between 0° and 250° . Special precautions were taken to insure purity of test sample and accuracy in exptl. details. Two series of measurements were in excellent agreement. After correcting for the diamagnetism of the remainder of the mol., the at. susceptibility of the Fe is very approx. inversely proportional to the abs. temp. The moment is 11.95 Weiss magnetons with θ of the Weiss-Curie law -13° abs. Other measurements between 0° and -80° seem to indicate that in this temp. range the moment is 13 magnetons, thus confirming the earlier work of Honda and Ishiwara (*Sci. Repts. Tokio* **3**, 303(1914)). W. W. STIFLER

Magnetic moment of iron in complex salts. L. A. WELO AND O. BAUDISCH. Rockefeller Inst. for Med. Research. *Phys. Rev.* **29**, 612(1927); cf. *C. A.* **20**, 2781.—

The moment of Fe is 29 magnetons in Fe^{+++} , 26 in Fe^{++} , zero in ferrocyanides, the pentacarbonyl and the nitroprusside, 10 in ferricyanides being about the same as in the bivalent Cu ion. Other moments in Fe may be found which may correspond to ions of other transition elements and to test this 45 rare Fe salts were examd. Of these, 28 salts behaved like simple Fe^{+++} , 7 salts, hexaacetates of the type $[\text{Fe}_2(\text{CH}_3\text{COO})_6(\text{OH})_2]\text{Cl}$ show a moment of 16 which is the same as the Ni ion, and a complex hexabenzozoate also has this value. Two complex glycolates correspond to the Cr ion with 19. It was assumed that the salts obey the Curie law and expts. are to be made to test this.

S. L. B. ETHERTON

Magnetic moment of helium and molecular hydrogen. IRVIN H. SOLT. Univ. of Cincinnati. *Phys. Rev.* **29**, 904(1927).—The method of Gerlach and Stern was used with a field gradient of 1.5×10^6 gauss/cm. The beam of atoms or mols. was explored by a Pt wire 0.017 mm. in diam. and 2.5 mm. long which formed one arm of a Wheatstone's bridge. No influence of the magnetic field on the beam was observed.

W. W. STIFLER

An interferential method for measuring magnetic susceptibility of liquids. O. SPECCHIA. *Atti accad. Lincei* [6], **7**, 574-6(1928).—The app. and technic are described in detail. The method is rapid and precise and has several advantages over the Fabry method.

C. C. DAVIS

Magnetic moment of atomic iodine. JOHN B. TAYLOR and T. E. PHIPPS. Univ. of Illinois. *Phys. Rev.* **29**, 904(1927).—Rays of I dissociated in an electrically heated quartz tube furnace were received on a liquid-air-cooled glass target coated with a thin film of Hg. On spectroscopic grounds a multiple sept in a magnetic field corresponding to a magnetic moment of 2 has been predicted. The rather imperfect images obtained seem to agree with this.

W. W. STIFLER

Thermomagnetic effect on gases. NOEL C. LITTLE. Bowdoin College. *Phys. Rev.* **29**, 901(1927).—A temp. gradient was maintained in a gas enclosed in a metal box placed between the poles of an electromagnet. A non-uniform magnetic field warped the isothermal surfaces, the effect varying with the nature of the gas. With a temp. gradient of 15° per cm., a thermocouple placed midway between the poles showed drops of 16° in air, 18° in O_2 , 6.6° in H_2 and 16° in propane when a field of 15 kilogausses was excited. N_2 and CO_2 showed no effect.

W. W. STIFLER

The optical properties and changes in state of zircon. W. FR. EPLER. *Z. Krist.* **64**, 510-11; *Physik. Ber.* **8**, 734(1927).—According to Stevanovic there are 3 kinds of zircon distinguished by d. a has a d. of 4.0 unchanged on heating; b has a const. value 4.7; c is unstable and goes over to b on heating. Densities and refractivities are now detd. on 7 specimens of different colors. Hyacinth from Laacher See at 197° has a reversible change in n of 30 units in the 4th decimal place. With c -zircon (green from Ceylon) there is a monotropic modification change at 1950° to normal b -zircon. Reversible color changes were observed, the color being due to content of Si, Zn, Hf, Ti, Cu, Fe, Zn and Ca.

G. I. CLARK

The law of mixed actions. ALEXANDER SOOS. *Chem. Rundschau Mitteleuropa u. Balkan* **3**, 129-31, 137-40, 148-50(1926); *Chem. Zentr.* **1927**, I, 1926.—Actions (such as light absorption, or rotation of the polarization plane) which affect substances as a function of the layer thickness form the resultant of 2 originally different components, after emerging from the substance. They are quantized, i. e., their transmission is accompanied by quantized variations of state. A plot of action vs. layer thickness gives a wavy line; the "elemental thickness" may be calcd. from the wave length. S. defines as "elemental thickness" h , a layer in which the dissolved particles cover completely, but once only, a plane of projection, the limit of absorption bands for instance. S. detcs. the absorption of light through Au, Ag and MnO hydrosols, in a Martens-Grunbaum polarizing spectrophotometer, increasing the thickness by 0.5 to 1.0 mm. each time. Values of h ranging between 4 and 10 mm. are found. S. calcd. the particle sizes (assumed to be cubic) of Au sols prepd. at different temps., by Zsigmondy's ultramicroscopical method, and by the law of mixed actions. The latter method gives values for the edge of the cube 100 times smaller than the former. S. explains it by assuming that the ultramicroscope detects only the larger particles and that a mol. does perhaps not absorb in its whole vol. as defined. The quotient $S = h^2/\pi r^2$ (r = particle radius), is called the "elemental number." At const. concn., it is independent of dispersion or of h , and is characteristic of the elements or compds. The mol. projections actually overlap each other 2, 3, n times before the field is completely covered. This fact does not alter the law of mixed actions.

A. L. HENNE

The reflecting power and color sequences shown by metals on activation. F. HURN CONSTABLE. St. John's College, Cambridge. *Nature* **122**, 57(1928).—Hinshel-

wood (C. A. 17, 657) observed that the brightening of color sequences on repeated oxidation and reduction shown by Cu goes hand-in-hand with increase in catalytic activity. That the brightening of the color sequence is due to the increased reflecting power (I) of the underlying metal, and that the I of Fe, Ni and Cu when reduced from the granular oxide increases with the no. of oxidations and reductions until a limiting value of I is reached has been shown spectrometrically (C. A. 22, 1720). It has now been shown experimentally that a burnished metal surface becomes duller on activation and that the color changes accompanying it become less pronounced. J. BALOZIAN

The azo-chromophore. I and II. J. S. PETRUS BLUMBERGER. *Chem. Weekblad* 25, 282-6, 315-8(1928).—The attempt is made to connect the color with the modern valency theories. An asymmetric position of the azo group (elec. polarity) gives rise to a powerful selective absorption. The factors increasing this polarity have a bathochromic effect, and *vice-versa*. A. L. HENNE

Graphic representation of colors. S. RÖSCH. *Physik. Z.* 29, 83 91(1928).—Every color can be defined by means of its "relative brightness," the relative width of its spectrum and the mean wave length. An app. is described whereby any color may be compared by synthesis in terms of these 3 coordinates B. C. A.

Optical and electrical properties of liquids. C. V. RAMAN AND K. S. KRISHNAN. *Proc. Roy. Soc.* 117A, 589-99(1928); cf. C. A. 21, 1053, 2419.—Theoretical. A review of the existing theories of the optical and elec. behavior of liquids shows that they are inadequate to explain the changes of refractivity and dielec. behavior with d. and temp. A new theory is developed based on the assumption that the mols. of a liquid are optically and electrically anisotropic, and that the polarization field acting on a mol is a function of its orientation. The formulas deduced are used to show why with increase of d. the Lorentz refraction const. usually diminishes. The changes in refractivity and dielec. const. are closely related to a change in the effective optical or electrical anisotropy of the mol. produced by the influence of its neighbors. The anisotropic consts. appearing in the formulas, can be evaluated with the aid of the theory of light-scattering in liquids previously developed (*loc. cit.*). B. C. A.

Variation in rotation and conductivity of sugars in aqueous solution with and without boric acid. II. R. VERSCHUUR. *Rec. trav. chim.* 47, 423 57(1928); cf. C. A. 22, 3142.—Numerous measurements of the rotatory powers and conductivities of solns. of maltose, levulose, α - and β -glucose, α - and β -galactose and inulin, both in absence and presence of boric acid, have been made. The cond. of maltose + boric acid shows a max. at equimol. concns. (0.5 M) and diminishes slightly with either increase or decrease of sugar. Levulose is the only sugar for which the consts. of mutarotation and cond. are proportional to the concn. of boric acid, and it is found that even traces of the acid cause a large increase in the cond. Dextrose shows a greater increase in cond. than does galactose, if comparison is made between the equil. mixts. In view of the above results and those previously obtained (*loc. cit.*), the structural formulas of xylose, arabinose, dextrose, galactose and mannose are discussed. B. C. A.

Absolute intensity measurements on a sodium burner and the life period derived from them. E. F. M. VAN DER HELD. Univ. Utrecht. *Physica* 8, 165-71(1928).—A review is given of expts. on the detn. of the time of excitation of Na atoms for the D line by measurement of the abs. intensity of the latter. A Na_2CO_3 soln. was dispersed in a flame of illuminating gas with a flame velocity of 418 cm. per sec. (Andrade method with revolving mirror and C particles), radius of 1.7 cm. The flame temp. was found by inserting a hot Pt filament in the flame and balancing the radiation from it as called from its optically detd. temp. with the elec. energy used. It was found to be $1970^\circ \pm 20$ abs. The light examd. was taken from a 1.08×1.14 -cm. strip of the flame, its intensity measured by the method (cf. van Dyck, C. A. 22, 21) of the abs. thermopile. The Na vaporized was found by weighing and no concn. changes were noticed. For a comparison radiator a quartz mercury lamp, previously standardized, was used (green line). The Na flame observations consisted of 3 abs. ones, direct spectrographic comparison with the Hg lamp, and 2 relative ones, comparison of Na intensities for varying flame concns. For a no. of atoms per cu. cm. $N = 4.16 \times 10^{14}$ to 7.12×10^{16} were found ratios of 0.199 to 1.15 (for normalities 1/1.17 to 1/10480), the relative width of the Hg lamp being from 0.066 to 0.0098. The calcd. quanta per sec. per atom q varied from 10.2 to 243 under these conditions. Plotting q against $\log \rho$ ($\rho = 4\pi N e^3/m$) gives an S-curve, in which q approaches 250 for extreme flame dilns. (no absorption). With this value in Einstein's equation for the time of excitation a value of 5×10^{-8} sec. is found higher than Minkowski's (1.6) by magnetic rotation, in fair agreement with Kerschbaum's of 4×10^{-8} . For the intensity ratio of the 2 D lines was found at the lowest concn. used 1:2.05. B. J. C. VAN DER HOEVEN

Refractivity of normal saturated monobasic aliphatic acids. P. E. VERKADE AND J. COORS, JR. *Rec. trav. chim.* **47**, 415-7(1928); cf. *C. A.* **22**, 571, 1326.—A polemic on the refractivity of the fatty acids. The mol. coeff. of refractivity is a phys. quantity whose const. homology increments $\Delta(M/d)$ and $\Delta(M, n)$ first occur in the rather higher members of the series. Abnormally small mol. vols. and high mol. coeffs. of refractivity cause homology increments to behave irregularly for initial members. Such data as are available on the latter therefore are of no value in detg. the oscillation phenomenon by means of mol. refractivity.

RAYMOND H. LAMBERT

The degree of association of sodium vapor. DONALD S. VILLARS. Univ. of Ill. *Proc. Nat. Acad. Sci.* **14**, 508-11(1928).—A detn. of the heat of dissoen. of the mol. Na_2 , was made from band-spectra observations and from this, by using the theoretical Sackur-Tetrode equation, the degree of assocn. was estd. The results contradict all previous hypotheses concerning the monatomicity of Na vapor and indicate that a very large portion of it is diatomic.

MALCOLM DOLÉ

A new method for observing the smallest birefringence. G. TODESCO. *Atti accad. Lincei* [6], **7**, 394-9(1928).—The method is based on the use of a photoelec. cell located to receive the light, which by means of interposing the birefringent object between 2 crossed Nicol prisms, emerges from the Nicol analyzer. The app. and technic are described in detail with diagrams. The app. is extremely sensitive, and the distribution of internal forces of glass subjected to pressure, tension or flexure can be detd. *Magnetic and elec. birefringence* are also readily measured. The Majorana effect in colloidal Fe is very distinct. Various substances are being studied with the new app.

Application of the quantum mechanics to the structure of the hydrogen molecule and hydrogen molecule ion and to related problems. LINUS PAULING. California Inst. of Technology. *Chem. Reviews* 173-213.—A general account of the application of quantum mechanics to the problems of mol. formation and decompn. A new first-order perturbation treatment of the H_2 molecule ion is given. W. WE-R

Comprehensive form of energy-level diagram for atoms. RAYMOND T. BIRGE. Univ. of California. *Phys. Rev.* 29, 922(1927).—The diagram is intended to include all energy levels of an atom and its singly, doubly, etc., charged ion, provided not more than one electron is in an excited level. For the neutral atom all levels are represented by parallel sets of vertical columns, grouped in one section. All the levels of the singly charged atom are grouped in an adjoining section. Transitions representing monochromatic radiation do not cross the division between sections, while all crit. absorption limits do cross. W. W. STIFLER

Coordination and atomic structure. P. RAY. *J. Indian Chem. Soc.* 5, 73-89 (1928).—Views concerning the electronic configuration of complex compds. are summarized, and a scheme for electron distribution in complexes is suggested. Complex compds. are differentiated as strong (perfect) or weak (imperfect), the former include most six-fold cobaltic, some six-fold ferrous and ferric, all six-fold and four-fold Pt, and the six-fold chromic, tervalent Rh, tervalent and quadrivalent Ir and a few Ru complexes, while the latter are transitional between true complexes and double or assoc. compds., e. g., Ni, Cu, Zn, Ca and cobaltous complexes. Tendency to assume the external electronic configuration of the next higher inert gas by the central ion is the main factor in the formation of perfect complexes. For the weak class it is assumed that the various units share electrons with the central ion at different levels, in the perfect class a more or less inner level of electrons takes part in the sharing. Thus the nature of the electron distribution in the central ion det. the type of coordination. The stability of the complex increases with the number of electrons in any sub-group as it gradually becomes filled up, a lone electron tends towards instability. B. C. A.

The statistical deduction of some properties of the atom. III. Calculation of the Rydberg correction for the s terms. E. FERMI. *Atti accad. Lincei* [6], 7, 726-30(1928), cf. *C. A.* 22, 1721, 2314.—Mathematical. The value of s terms of the spectra of all the elements, *i. e.*, the Rydberg correction of the s series, is calcd. A graphical representation of the results, where the abscissas are the at. nos. and the ordinates are Rydberg corrections, shows good concordance between exptl. data and theory. C. C. DAVIS

Velocity of cadmium atoms regularly reflected from a rock-salt crystal. A. ELLERT AND H. F. OLSON. *Science* 68, 89(1928).—The specularly reflected beam of Cd atoms produced by the incidence of a beam of such atoms on the cleavage face of a rock-salt crystal was found for 3 angles of incidence, 22.5°, 45° and 67.5°, to consist of atoms whose velocities were very nearly the same; the velocity of the atoms in the reflected beam was independent of the temp. of the crystal for temps. from 200° to 500°. If the assumption is made that in the deBroglie equation for the wave length of the phase wave assoc. with the particle of mass M , $\lambda = h/MV$, the mass of a single proton, and not that of the atom is to be substituted, and, further, that the reflection law is the same as that used by Davisson and Germer for reflection of electrons by crystals, namely, $n\lambda = nh/MV = 2d(\mu^2 - \sin^2\theta)^{1/2}$, where n in this case is 1, values for the velocity of the reflected atoms are obtained which are in close agreement with expt. W. WEST

"Nebulium" spectrum in new stars. C. T. FLVEY. *Nature* 121, 453(1928).—The discrepancy between the conclusions of Pike (*C. A.* 22, 1532) and those of E. are ascribed to the inapplicability of the theory of thermal ionization. B. C. A.

An attempt partially to separate the isotopes of cadmium. ARTHUR A. SUNIER. *Abstracts of Theses, Univ. Chicago, Science Series* 4, 173-7(1925-6).—No difference in at. wt. is found for 2 extreme fractions of Cd produced by 13 successive evapns. in vacuum, in each of which the amt. is decreased by $1/2$. The neg. result may be due to the slowness of self-diffusion in molten Ca. A study is made of the most advantageous scheme of fractionation. The relative at. wts. of the final samples were studied by comparing the densities of cast pellets, and the precautions necessary to obtain Cd castings of uniform density are given. F. A. JENKINS

The separation of the element chlorine into isotopes (isotopic elements): Light fraction. FRANCIS A. JENKINS. *Abstracts of Theses, Univ. Chicago, Science Series 4*, 93-8(1925-6).—By a systematic fractionation of HCl gas, consisting of diffusions against air at atm. pressure through porous pipe-stems, 28 g. of HCl is obtained in which the Cl has an at. wt. 35,418, as found from the ratio Ag/AgCl. At. wt. changes for intermediate fractions are detd. from the densities of HCl solus., and afford a comparison of the efficiencies of 2 forms of *diffusion app.*

F. A. JENKINS

New theory of the origin of the actinium series. T. R. WILKINS. Univ. of Rochester. *Phys. Rev.* **29**, 352(1928).—It is suggested that the Act series comes from an isotope of U (actino-uranium I) whose decay const. is several times that of U_1 . This would explain the variations of the radii of pleochroic rocks. Decay consts. of actino-uranium are calcd. from a study of haloes. Some uranium Pb is due to Act. The ages of rocks calcd. from Pb or He content is probably as much as 40% in error in the oldest rocks.

L. D. ROBERTS

The number of ions produced by radium C' in air. IRENE CURIE AND FREDERIC JOLIOT. *Compt. rend.* **186**, 1722-4(1928).—The app. of Mme. P. Curie (C. A. **19**, 2448) for the estn. of very intense α -ray sources is used. Ionization currents equiv. to $1/10,000$ part of total α -radiation are measured. These measurements are obtained in the presence and absence of a magnetic field and with the interposition of a series of screens of Al 0.02-0.1 mm. in thickness. Numerical results are deferred to another paper.

H. R. MOORE

Apparent evidence of polarization in a beam of β -rays. R. T. COX, C. G. MCILWRAITH AND H. KURRELMAYER. New York Univ. and Columbia Univ. *Proc. Nat. Acad. Sci.* **14**, 544-9(1928).—Preliminary attempts to obtain exptl. evidence of polarization in a beam of β rays are described and discussed. The "somewhat inconclusive results" seem to indicate a true polarization due to the double scattering of asymmetrical electrons.

MALCOLM DOLE

The scintillation method. BERTA KARLIK AND ELISABETH KARA-MICHAILOVA. *Z. Physik* **48**, 765-83(1928).—The factors concerned in the scintillation method for counting α -particles, H particles, etc., are analyzed. ZnS screens, which phosphoresce in the region of max. sensitivity of the eye, were used in the expts. Quant. expts. were performed with a comparison microscope provided with 2 objectives and a common eyepiece. Scintillations from α -particles are 3 times as intense as those from H particles. For α -rays the intensity of scintillation is detd. by the energy transferred to the phosphorescent crystal. Measurements of the total intensity made by a photoelectric cell show proportionality of the intensity to the number of α -particles. The prepn. and testing of phosphorescent screens are considered in the light of the results obtained.

W. WEST

Preparation of highly concentrated polonium preparation by distillation. ELISABETH RONA AND EWALD A. W. SCHMIDT. *Z. Physik* **48**, 784-9(1928).—The concn. of Po on metallic surfaces by the original method of I. Curie, by pptn. of Po from concd. almost neutral soln. on Ag or Ni sheets rotating for about 20 hrs. in the soln., suffers from the disadvantages of requiring great purity of the initial materials, fine adjustment of the soln., and of the impossibility of further concn., once the sheet has been removed from soln. These disadvantages are evaded by the following distn. method. Po is first sepd. on large Pt electrodes by electrolysis of Ra D soln. contg. 0.1 N HNO_3 with a c. d. of 5×10^{-6} amp./sq. cm. The electrode is cut into strips 1 cm. \times 0.3 cm. and a strip placed in the constricted part of a quartz tube and distd. by heating with a micro-oxygen blow lamp on to Pd or Pt plates 3 mm. diam. placed in the wider part, and kept cool by contact with a large Cu rod. The distn. is carried out in a slow stream of pure H_2 . Point preps. can be similarly made. Preps. of strengths up to 20,000 e. s. u. on sheets of 4 sq. mm. area and point preps. of 1400 e. s. u. per sq. mm. have been made. It was also shown that the radiation from different points of these surfaces was quite uniform.

W. WEST

The radioactivity of the lighter elements. WILLIAM G. GUY. *Abstracts of Theses, Univ. Chicago, Science Series 4*, 87-91(1925-6).—A method of balancing the ionization currents from two chambers charged to opposite potentials is used to detect radioactivity. The arrangement will detect an activity of $1/300$ of the β -radiation from K. No activity is found for salts of Na, Ca, Ba, Sr, C, Cl, Br, Cu, Fe, Pb, Mg, Mn, Ni, Ag and Zn, or for the elements Ta, W, La, Se, As, Sn, Au, Sb, Al and Hg. The activities of Rb and K are found to be in the ratio 1.39/1.00. The absorption coeff. in Al of the β -rays from KCl under satn. conditions varies from 39.6 to 55.4 with Al thicknesses 0.0135 to 0.0405 cm., while with Rb salts it decreases from 593 to 522 with Al thicknesses 0.0017 to 0.0051 cm. Certain org. salts of K show an anomalous behavior in

that they retard the electrometer deflection instead of accelerating it. The effect is ascribed to the presence of a free surface charge on the compd. F. A. JENKINS

Physical-chemical investigations of ordinary and uranium-lead chloride. W. A. ROTH AND O. SCHWARTZ. Braunschweig Tech. Hochschule. *Ber.* **61B**, 1539-45(1928).—The phys.-chem. constns. of ordinary and uranium PbCl_2 are measured; salts carefully purified by repeated crystn. from HCl are used. Density is detd. in ethylene bromide, a xylene mixt. ($d_{18} = 0.86451$), and a satd. H_2O soln. of PbCl_2 in the case of the ordinary salt or a satd. HCl soln. in the case of uranium PbCl_2 . d_{18} for the ordinary salt is 5.909 ± 0.001 and for the U salt 5.884 ± 0.001 . Calcn. of mol. vol. from the d. detns. gives 47.07 cc. in each case. d_{18} for concd. solns. is given as 1.00720 for ordinary PbCl_2 and 1.00716 for uranium PbCl_2 . Measurement of the n of H_2O solns. shows that, while the mol. refraction is the same for the 2 salts, the increase in the n of H_2O is slightly greater for the U isotope than for ordinary PbCl_2 . Elec. cond. of the 2 salts is practically equal, the equiv. cond. of a 0.062 N soln. at 18° being 75.4. Heat of pptn. as chromate is likewise equal and is given as 11.17 kg.-cal. per mol. at 18° . H. S.

Electron counting tube for the measurement of weak activities. H. GEIGER AND W. MÜLLER. *Naturwissenschaften* **16**, 617-8(1928).—A thin wire covered with a uniform poorly conducting surface film is axially suspended in a metal tube. The insulating skin allows the wire-wall potential to rise above the spark value. This causes an electron ray penetrating the wall to give a powerful ionization current which stops rapidly on charging the insulating skin. The individual current peaks can easily be demonstrated by a string electrometer. The app. as a whole represents a counter for corpuscular rays with the whole surface of the external cylinder as active opening. The recording intensity is actually proportional to the tube surface and, over a range of 50 v., independent of the potential. It is extremely sensitive; hundreds of hits were recorded in one min. from cosmic radiation, radiation of room objects, etc. With an 80-sq. cm. tube and 25-cm. iron armor this no. was reduced to 0.6 per min. per sq. cm. surface. The γ -radiation of K could be shown on 100 g. KCl in a few min.; 50 mg. KCl inside the armor prevented any other observations due to β -radiation of K. Activities of one thousandth the K activity can be measured. B. J. C. v. D. H.

Quantum theory of the spinning electron. FRIEDRICH MÖGLICH. *Z. Physik* **48**, 852-67(1928).—A formal amplification of Dirac's treatment of relativistic quantum mechanics (C. A. **22**, 1535). In particular the transformations are considered which replace the Lorentz transformations for the electron spin and the characteristic functions. A Lagrange function is further found from which, by variation, both the Dirac and the Maxwell equations can be obtained. W. WEST

Relation between the spectral lines of hydrogen and of ionized helium and the movements of the electrons. A. M. TIROV. *Ann. Inst. Polytech. Oural* **5**, 37-48(1926).—Mathematical. B. C. A.

Magnetic analysis of a luminous canal-ray beam in hydrogen. C. J. BRASEFIELD. *Phys. Rev.* **31**, 215-9(1928).—A luminous canal-ray beam in H is sepd. by means of a transverse magnetic field into 4 component parts: neutral particles, and the charged ions H_2^+ , H^+ and H_2^{+-1} , (ions which passed through the elec. field as H_2^+ , but disocd. into H^+ before reaching the magnetic field). Measurements of the variation of the intensity of the H_2^+ and H_2^{+-1} beams with the pressure lead to a value for the free path for disocn. of a 1000-v. H_2^+ ion into H_2^{+-1} of 0.37 cm. at 0.01 mm., about 0.25 of the value, calcd. from the kinetic theory, for the neutral mol. B. C. A.

Electronic emission in a vacuum tube. L. TIERI AND J. RICCA. Univ. Messina. *Atti accad. Lincei* [6], **7**, 720-6(1928).—The object of the expts. was to det. whether there is a relation between variations of the filament current and variations of the thermionic current when the potential between the plate and filament was increased. The app. and technic are described in detail, with diagram. The results, which are recorded graphically, are to be interpreted in a forthcoming paper. C. C. DAVIS

Electric discharge in rarefied gases. Distribution of the electric field in the dark space. M. MORAND. *J. phys. radium* **B**, 451-72(1927); *Science Abstracts* **31A**, 202.—According to the ideas developed by Townsend and others the persistence of the discharge in a rarefied gas is due both to ionization by pos. rays and to the cathodic emission. A simple and general method of calcn. is here used to show that the exptl. laws discovered with regard to the distribution of the elec. field in the dark space are only explicable if pos.-ray ionization is effective. If λ is the mean free path given by the kinetic theory for an ordinary mol., comparison of exptl. curves with theoretical results shows that (1) for the pos. rays, whose mean free path is, on account of their velocity, equal to $\lambda\sqrt{2}$, the calcd. ionizing power is near that detd. by Townsend:

(2) the cathode rays, whose mean free path is $4\lambda\sqrt{2}$, produce on an av. 2 ions for every 3 or 4 impacts; (3) the current of pos. ions issuing from the neg. glow is, in general, only a small fraction of the total current traversing the discharge tube; (4) the cathodic emission represents an appreciable fraction of the total current in the tube. In the majority of cases cathodic emission gives to the discharge a certain instability. The current traversing the tube can only be const. if a certain condition relative to the no. of ions formed in the dark space by the cathode rays is fulfilled. When this condition is satisfied, ionization by pos. rays should necessarily take place also. Thus the conclusions are in agreement with Townsend's results. H. G.

Electron emission and diffusion constants for tungsten filaments containing various oxides. S. DUSHMAN, D. DENNISON AND N. B. REYNOLDS. Gen. Elec. Co. *Phys. Rev.* **29**, 903(1927); cf. *C. A.* **21**, 2220.—The emission phenomena are similar to those observed with thoriated W filaments. The values of A and b , resp., in the thermionic emission equation are for Y 7.0, 31,300; La 8.0, 31,500; Ce 8.0, 31,500; Zr 5.0, 36,500; U 3.2, 33,000; Th 3.0, 30,500. Data are also given for the diffusion consts. and heat of diffusion of U, Th, Ce, Zr and Y. W. W. STIFLER

The resistivity of thin metallic coats obtained by cathodic atomization. FREDERIC JOLIOU. *Compt. rend.* **186**, 1526-8(1928).—Pt films have been deposited on glass by cathodic atomization; the film thickness was detd. by weighing with a microbalance. For a const. thickness, the resistivity decreases when the anode-cathode tension increases. When the Pt film is heated, the resistance increases first linearly, until it reaches a max.; then it decreases. By cooling the film down to -185° , the resistance decreases linearly; the latter phenomenon is entirely reversible. The effect of a long heating is to remove the gases included in the Pt film, so that its resistivity and its temp. coeff. tends to be the same as in the case of solid Pt. If the Pt films are not carefully maintained at const. temp., the heat evolved by the current during the expt. will offset the measurements. A. L. HENNE

Dissociation of hydrogen chloride by positive-ion impact. WALTER M. NIELSEN. Duke Univ. *Phys. Rev.* **29**, 907(1927).—Pos ions were projected between two electrodes P_1 and P_2 toward a third electrode P_3 . HCl was fed in through a fine capillary at a pressure corresponding to a mean free path of 2 cm. With a potential on P_1 such as to prevent pos. ions from reaching it and with a small drawing out potential for positive ions on P_2 and P_3 , no neg. current to P_1 was observed for a driving potential less than 34 v. Above this value the ratio of neg. current to total pos. current increased rapidly with the driving potential. W. W. STIFLER

Electron emission in intense electric fields. R. H. FOWLER AND L. NORDHEIM. *Proc. Roy. Soc. (London)* **A119**, 173-81(1928).—No theoretical justification can be found for the proposed simple equation connecting thermionic and strong field emission of electrons from a metal. The formula which includes the effect of an external field is shown to be independent of T at low temps. Potential energies as found exptly. are rounded off by an image effect but this fact does not appreciably alter the results obtained. The treatment has been carried out by using the same underlying picture of the metal as given by Sommerfeld. RAYMOND H. LAMBERT

Reflection of electrons from molybdenum. W. R. HAM. Penn. State College. *Phys. Rev.* **29**, 908(1927).—The % of reflected electrons relative to incident electrons was plotted against velocity of reflected electrons from data obtained from several water-cooled Coolidge tubes with Mo anticathodes, operated at various potentials between 1000 and 22,000 v. Peaks of reflection seem to occur as the impressed voltage passes the crit. potentials for the L levels of Mo, and also probably for the K level. Residual gas seems to have little if any effect on the results. W. W. STIFLER

O- and N-energy levels in the secondary emission of hot tungsten. HERMANN E. KREFFT. Gen. Elec. Co. *Phys. Rev.* **29**, 908(1927).—The secondary emission was measured from W at about 1200° K. A no. of breaks in the curve were found for velocities corresponding to voltages between 5 and 750 v. A particularly prominent one at 70.5 v. seems to correspond to the O_1 -level and is in excellent agreement with the previous work of Bohr and Coster. Other breaks are in agreement with the values computed by Nishina for the N_I , N_{II} and N_{III} levels. W. W. STIFLER

Angular scattering of electrons in hydrogen and helium. GAYLORD P. HARNWELL. Cal. Inst. of Tech. *Proc. Nat. Acad. Sci.* **14**, 564-9(1928).—"No favored angles for electron scattering from H_2 or from He were observed, and in the case of He the results obtained by Dymond were not able to be reproduced." H. covered the inside of his scattering chamber with Mg, which prevented the charging up of the glass walls of the scattering bulb and consequent deflection of the electron stream by the electrostatic charge. MALCOLM DOLÉ

Velocity distribution and 180° scattering of low-velocity electrons from iron. H. E. FARNSWORTH. Brown Univ. *Phys. Rev.* **29**, 908-9 (1927).—The no. of electrons leaving an Fe target nearly normally was measured relative to the total no. The results give no evidence of inelastic collisions. The fraction, for primary velocities of a few volts, is much greater than that predicted by a cosine law of distribution, and decreases rapidly with increasing primary velocity up to approx. 30 v. W. W. STIFLER

Residual ions and critical restriking potential in mercury arcs. M. L. POOL. Univ. of Chicago. *Phys. Rev.* **29**, 915 (1927).—The restriking of a Hg arc at the lowest radiating potential is attributed to the large concn. of electrons and positive ions near the filament. Under certain conditions it may result from the ionization of the metastable atoms formed by continual recombination. W. W. STIFLER

A possible relation between radiation and ionization potentials of iron. ORTO STUHLMAN. Univ. of N. C. *Phys. Rev.* **29**, 354 (1927).—By retaining (I) potentials 11.1, 19.4, 41.2, 54.6, 103.5, 169.4, detd. by Thomas and new (I) potentials of 5.72, 7.29, 11.14 and a (R) potential at 8.14 v., all crit. (R) potentials can probably be attributed to multiple impact. L. D. R.

The 29-volt critical potential of hydrogen. ROGERS D. RUSK. N. Central College. *Phys. Rev.* **29**, 354 (1927).—A tube contg. 2 hot filaments and 2 Ni anodes gave low-voltage arc characteristics for varying anode distances and gas pressures in H. For the type of glow observed 29 v. was the lowest maintaining potential. L. D. R.

Polarization of canal-ray light in weak electric fields. I. H α -radiation in a transverse field. E. RUPP. *Ann. Physik* **85**, 515-28 (1928), cf. *C. A.* **22**, 727. The polarization ratio I_p/I_s (I_p being the intensity parallel to, and I_s that at right angles to the ray axis), of the H β -line from canal-ray light in weak elec. fields, has been detd. for various fields and velocities. When the polarization ratios for points along the canal-ray stream are plotted against the distance, the curves exhibit characteristic periodicities, which become more marked with decreasing velocities and increasing fields. The phenomena are qualitatively in accord with the oscillations of a classical anharmonic oscillator showing different phases along the stream. B. C. A.

Significance of photoelectric conduction in crystals. A. M. MACMAHON. Univ. of Chicago. *Phys. Rev.* **29**, 902 (1927).—The theory of the Rutherford Bohr atom is applied, with certain appropriate modifications, to the conduction of electricity in light-sensitive crystals such as Se. The differential equations thus obtained are said to be in agreement with the exptl. facts. W. W. STIFLER

Effect of oxygen on photoelectric emission from potassium. I. R. KOLLER. Gen. Elec. Co. *Phys. Rev.* **29**, 902-3 (1927).—An adsorbed layer of O one atom deep produced no effect on the sensitivity of a K photoelectric cell. Addn. of O up to 355 microns produced no appreciable effect. The next 800 microns increased the sensitivity three-fold, after which additional doses of O produced an immediate drop followed by a gradual recovery, but for each successive addn. the drop was to a lower level and the recovery less complete. This is explained by the absorption of O by the K. Small amts. diffuse into the K, leaving no oxide on the surface. When the K is nearly satd. the diffusion takes place more slowly. W. W. STIFLER

Photoelectric cell for medium ultra-violet. I. MALLET AND R. CLIQUET. *Compt. rend.* **185**, 1031-3 (1927). *Science Abstracts* **31A**, 209.—The KH cell is not sensitive to wave lengths below 3600 Å. U. Zillard has constructed a Cd cell sensitive as far as 2900 Å. U. The authors adopt an alloy of Cd and Ag, which is quite insensible to the visible spectrum, but shows a max. photoelec. effect at 2536 Å. U. H. G.

Periodicity of photoelectric thresholds. GEORGE B. WELSH. Cornell Univ. *Phys. Rev.* **29**, 615.—The photoelec. threshold may be considered a measure of energy taken from the incident radiation to detach one of the outer electrons from its atom. Consequently, the elements with most loosely bound electrons should permit detachment with expenditure of min. amts. of energy. The curve for photoelec. thresholds and at. nos. shows a periodicity with a max. for alkali metals and minor peaks for Cu and Ag but none for Au although one may be expected. The values of Ge and Be thresholds are given; they fall upon the curve. S. L. B. ETHERTON

Remark on Rud. Suhrmann's note. "A novel photoelectric effect of thin alkali metal films." B. GUDDEN. Univ. Erlangen. *Naturwissenschaften* **16**, 547 (1928); cf. *C. A.* **22**, 2512.—G. explains the quasi-free electrons found by Suhrmann for thin films and low frequencies by local differences (spots) of the condition of the metal film (cf. Richardson and Young, *C. A.* **19**, 1813). These spots cause potential differences of several 0.1 v. in the exit work of the electrons and consequently local fields, with resulting deviations of electrons and difficulty in reaching satn. conditions. The cause

of the spots is probably incomplete covering of the underlying material.

Remark on the communication: "A novel photoelectric effect of thin alkali metal films." RUD. SUHRMANN. *Techn. Hochschule, Breslau. Naturwissenschaften* 16, 616-7(1928); cf. preceding abstract.—It is believed that the magnitude of the effect described is too large to admit Gudden's explanation of spots on the surface. Rather will R.'s explanation hold of a retarding ion layer. Examn. of the temp. influence will allow a definite decision on this point.

Theory of the magnetic nature of gravity and electrons. CORNELIO L. SAGUI. Castelnovo dei Sabbioni, Italy. *Phys. Rev.* 29, 906(1927).—Electrons are considered as an assembly of a large no. of electromagnetic quanta while protons result from an assembly of electrons, the pos. charge being due to a symmetrical difference in structure. The frequencies predicted by Einstein's photoelec. equation are explained as due to the splitting up of the electrons themselves into smaller units of energy, the effect being wholly mech.

Existence of zero-point energy in the rock-salt lattice by an x-ray diffraction method. R. W. JAMES, I. WALLER AND D. R. HARTREE. *Proc. Roy. Soc. (London)* A118, 334-50(1928).—Within certain limits of frequency, the atomic scattering curve (giving F as a function of $\sin \theta / \lambda$, λ being the wave length of the radiation employed and 2θ the angle of scattering) of an atom for x-radiation can be calcd. by assuming that every element of charge scatters according to the classical laws. The F curves calcd. from the Schrodinger distribution of charge for the ions of Na and Cl, obtained theoretically by an approx. method, are compared with the exptl. values of F obtained from an investigation of the temp. factor of x-ray reflexion from rock salt (*C. A.* 22, 2691). The F -curves so calcd. are in very close agreement with the exptl. curves, if it is assumed that the crystal possesses zero-point energy of half a quantum per degree of freedom, as proposed by Planck. For both Na and Cl the observed curve is higher than the calcd. one for small values of θ . For somewhat higher angles the observed curve falls below the calcd. one, but crosses it again and lies slightly above it for values of $\sin \theta / \lambda$ greater than 0.9. The difference between the F -curves with and without zero-point energy is very considerable, especially for large angles of scattering, since the mean amplitudes of vibration of the atoms at zero abs. are somewhat greater than the radii of the regions within which the d. distributions of the K-electrons are concd., and for high angles of scattering the form of the F -curves depends almost entirely on the K-electrons.

X-ray absorption formulas. S. J. M. ALLEN. Univ. of Cincinnati. *Phys. Rev.* 29, 918(1927); cf. *C. A.* 22, 1906(1928).—General formulas for the absorption of high-frequency x rays, based on Schroedinger's wave mechanics, are discussed and a complete equation with numerical values is given for the absorption of the L series of Ag.

Effects of the surface conditions on the intensity of reflection of x-rays by quartz. YOSHITARO SAKISAKA. *Bull. Inst. Phys. Chem. Res. (Tokyo)* 7, 748-62(1928); English Ed. 1, 66-7. —See *C. A.* 22, 2512.

L x-ray absorption edges of Sn (50), In (49), Cd (48), Ag (47), Pd (46), Rh (45) and Ru (44). G. D. VAN DYKE AND G. A. LINDSAY. *Phys. Rev.* 30, 562-6(1927); *Science Abstracts* 31A, 187.—The L x-ray absorption edges of the elements Sn (50), In (49), Cd (48), Ag (47), Pd (46), Rh (45) and Ru (44) have been photographed and measured with a Siegbahn vacuum spectrograph of the precision type. The absorbing screens were made of the pure elements, since in this case the values of the energy levels obtained are admittedly more characteristic of the element than if chem. compds. were used as absorbers. Tables of wave lengths of absorption edges and assocd. energy levels are given.

Absolute x-ray wave-length measurements. A. P. R. WADLUND. Univ. of Chicago. *Proc. Nat. Acad. Sci.* 14, 588-91(1928).—An exptl. method is described for making absolute x-ray wave-length detns. by means of a ruled grating. The following preliminary values are given, Cu K_{α} , 1.5374 \pm 0.0006 A. U., Fe K_{α} , 1.937 \pm 0.004 A. U., Mo K_{α} , 0.708 \pm 0.002 A. U.

The spectrum of x-rays from the back of a tungsten target. EGON LORENZ. Harvard Univ. *Proc. Nat. Acad. Sci.* 14, 582-8(1928).—With a W anode x-ray tube, L. measured the intensity distribution as a function of wave length of both the focal spot and the stem radiation. Voltages of 22,400, 36,500, 71,600 and 82,500 were used. The stem radiation seems to be produced mostly by secondary electrons knocked out from the levels of a W atom; the intensity is a function of the applied voltage first increasing and then decreasing as the voltage is raised. The absorption of a

primary electron in any level becomes nearly zero if its energy exceeds the excitation voltage of the level by about 40 times. MALCOLM DOLE

The spectrum and state of polarization of fluorescent x-rays. A. H. COMPTON. Univ. of Chicago. *Proc. Nat. Acad. Sci.* 14, 549-53(1928).—The spectrum of fluorescent x-rays from Ag shows no continuous spectrum, the radiation being more than 99% line radiation. By filtering the fluorescent beam, the homogeneity may be made as great as 98%. The relative intensity as well as the positions of the spectrum lines is approx. the same in the fluorescent as in the primary x-rays. The characteristic fluorescent x-rays from Ag are completely unpolarized, within a probable error of 0.5%. MALCOLM DOLE

Polarization factor in x-ray reflection. R. W. JAMES. *Nature* 121, 422 3(1928).—James and Firth's detns. of the at. scattering factor (*C. A.* 22, 2691) do not appear to be affected by errors arising from the degree of polarization of the incident beam. B. C. A.

The polarization of characteristic radiation. J. A. BEARDEN. Univ. of Chicago. *Proc. Nat. Acad. Sci.* 14, 539-42(1928).—Previous investigators have thought that characteristic radiation is polarized, but in this paper expts. were performed using a monochromatic beam of x-rays which indicated that characteristic radiation from an x-ray tube is probably unpolarized. The geometric symmetry of the app. was carefully tested. MALCOLM DOLE

The index of refraction of glass for x-rays of long wave length. JEAN THIBAUD. *Compt. rend.* 187, 219-21(1928).—The considerable discrepancies between the results of spectrographic measurements of long-wave-length x-rays by diffraction (a) from a crystal, and (b) from a ruled grating, may be explained as due to refraction within the crystal, which has an index of refraction less than unity, so that the difference, $\delta = 1 - \mu$. The purpose of the present exptl. work was to det. the index, μ , of glass for very soft x-rays by the total-reflection method, which depends on detg. the limiting angle of total reflection from a plane mirror. If θ_m is the limiting angle at which total reflection occurs, this is related to the index of refraction by the equations $\theta_m = \sqrt{2\delta} = \sqrt{2(1 - \mu)}$. A vacuum spectrograph (cf. *C. A.* 21, 3158) was used with photographic registration and monochromatic rays between 17 and 65 A. U. as follows: FeL α , O $_2$ K α , N $_2$ K α , CK α , MoM. The limiting angle was not sharply marked, and a qual relationship was shown by recording the angles at which the intensity had decreased to one-half. A more exact detn. was attempted by observing the extinction of the diffracted rays of higher orders. For $\lambda = 44.9$ A. U. there is a regular decrease between $\theta_m = 4.2 \times 10^{-2}$ and 6.4×10^{-2} . For $\lambda = 65$ A. U. there is a decrease between the angles 4.8×10^{-2} and 10.5×10^{-2} . The lack of sharpness can be attributed to the high absorption of the x-rays in the glass, which makes it extremely difficult to det. the limiting angle of reflection with high precision. The following values were obtained for $\delta \times 10^{-4}$: 0.07, 4.8, 13, 18.6, 30.5 for wave lengths of 1.5, 20, 44.9, 54.9 and 65 A. U., resp. Thus δ varies approx. as λ^3 and θ_m approx. linearly with λ . The observed angles varied between 21' and 3°. The theoretical formula of Drude-Lorentz gives values of θ_m approx. twice as large as those observed. A. W. KENNEY

A new method of x-ray spectrography. Application to the study of the orientation of fatty acids by mercury. JEAN J. TRILLAT. *Compt. rend.* 187, 168 9(1928).—The x-ray study of the orientation of long-chain org. compds. at surfaces has yielded much valuable information. The rotating-crystal method has proved particularly advantageous, but it would be interesting to study other interfaces than the liquid-solid or solid-solid. The object of the new method is to obtain without rotation a continuous series of angles between the beam of x-rays and the interface which is the object of study, as is accomplished by rotation of the specimen or by actual bending of a crystal like mica. The new technic consists in placing a small drop of Hg on a plane surface and covering it with the material to be studied. Thus the curvature of the drop gives all values of the angle between 0° and the angle of contact, and rotation is unnecessary. The material may be either liquid or solid. The drop of Hg is raised until it cuts in two the beam of x-rays, and the center of the drop may, with sufficient precision, be taken as the origin of the diffracted rays. The method has been tried in the study of the fatty acids with very clear photographs after one or two hrs.' exposure. In spite of the fact that the Hg is liquid, a perfectly oriented layer has been obtained at the interface, whether the fatty acid was liquid or solid. The spectra show a regular diminution corresponding to a linear increase in the interplanar distances with the number of C atoms. The excess acid gives either an amorphous halo if liquid or its own spectrum if solid. The effect of temp. has been followed up to 100°, where the orientation is still perfect. Publication of details will follow. A. W. KENNEY

The reflection of x-rays from glass and quartz. T. H. LABY, J. SHEARER AND R. BINGHAM. Univ. Melbourne. *Nature* 122, 96-7(1928).—Evidence is obtained for regular reflection of x-rays of about 50 A. U. from glass and quartz up to glancing angles of 45°. To produce the radiation, electrons of 10,000 and 375 v. from a Wehnelt cathode were used with Cu and C targets, resp. The observations were made with a vacuum spectrometer. The ratio of the intensities of the incident and reflected beams is 2:1 up to angles of 35°, and greater at larger angles. The reflected radiation is absorbed by glass and fluorite, penetrates 0.0006 mm. Al foil, and has a photographic intensity detd. by the electronic current in the tube at const. potential. These facts exclude the possibility of its being radiation of the Lyman-Millikan region or of longer wave length, and the potentials prevented the reflection of cathode rays to the plate. With the C target, the radiation was probably the K line, λ 45 A. U. The results do not seem to be reconcilable with the Lorentz dispersion formula. F. A. J.

Anomalous dispersion in the x-ray range. J. A. PRINS. *Naturwissenschaften* 16, 555-7(1928); cf. C. A. 22, 2512.—Photographs are shown of the reflected and direct x-ray on an Fe mirror. From these it appears that a slight anomalous dispersion exists (increase of angle of total reflection more than linear with λ). Also from measured values of this angle φ_m in a $\varphi_m - \lambda$ graph it follows that they lie on a theoretical curve $\varphi_m = (e\lambda/C\sqrt{\pi m}) \sqrt{A[1 + B(\lambda^2/\lambda_k^2)\ln(1 - (\lambda_k^2/\lambda^2))]}$, an equation of Kallmann and Mark (C. A. 22, 1905). The only assumption different from K. and M.'s is that the "total strength" of the K oscillators is taken equiv. to 1.3 (instead of 2). Several references are given. B. J. C. VAN DER HOEVEN

Explanation of Whiddington's rule for x-ray electrons. E. C. WATSON. California Inst. of Technology. *Phys. Rev.* 29, 919(1927).—According to Whiddington's pioneer investigations on the velocities of electrons ejected by x-rays, an electron can be ejected only when the incident radiation has a frequency double the value corresponding to the energy level of the electron concerned. This result, which Robinson failed to confirm, is now explained as due to the fact that Whiddington studied only those electrons which left the radiator in the forward direction of the x-ray beam, while Robinson worked with those leaving at right angles to it. W. W. STIFLER

Theory of atomic structure and spectral series. L. DÉCOMBE. *Compt. rend.* 185, 1263-5(1927); *Science Abstracts* 31A, 155-6.—L. develops the theory previously put forward, which regards the protons as spherical electrified films vibrating radially. The radial vibrations of the electrons probably do not have much to do with gravitation, but appear to be of fundamental importance spectroscopically. On certain assumptions there are deduced formulas for the frequency of this vibration in an electron the velocity of translation of which is zero, and for one with velocity v . The differences between the frequencies at different velocities are not large, and beats may result when two electrons have different velocities. The frequency of these beats, when the electrons are revolving in suitable circular Bohr orbits, follows Rydberg's formula. The frequency of the radial vibrations when $v = 0$ is calcd. as 1.2×10^{20} ; for an electron with velocity v this frequency is $1.2 \times 10^{20} + (\mu_0 v^2/2h)$, where μ_0 is the mass of an electron with velocity zero and h is Planck's const. The theory also explains the production of the continuous background of the x-ray spectrum, limited on the high-frequency side, when a metal is bombarded by electrons with velocity v , and also the production of the characteristic spectrum with the lines of the same series appearing simultaneously. H. G.

Images of the solar chromosphere obtained with the spectroheliograph with the infra-red line of ionized calcium, λ 8542. L. D'AZAMBUJA. *Compt. rend.* 187, 201-3 (1928). W. F. MEGGERS

Use of Winther's gauze in spectrophotometry. G. LANDSBERG. *Z. Physik* 46, 106-8(1927).—The use of a blackened gauze as a constant extinction filter (Winther, C. A. 17, 3284) has been examd. in the visible region and up to 2026 A. U. The extinction of such gauzes is const. within 1% in the range examd. B. C. A.

Intensity distribution in Fraunhofer lines. M. MINNAERT. *Z. Physik* 45, 610-9 (1927).—The distribution of intensity in the Fraunhofer lines H_α and CaK has been detd. The results are discussed with reference to those of von Kluiber (C. A. 21, 3553). B. C. A.

Use of single thermo-junctions and of echlette gratings in the far infra-red. Richard M. BADGER. *J. Optical Soc. Am.* 15, 370-3(1927).—Methods of focusing radiation of the order of 100 μ on to single thermo-junctions are described whereby the diffuse images due to aberrations in reflection are avoided. The construction of a simple echlette grating from plane parallel glass strips is also described. B. C. A.

The broadening of spectral lines. F. RASSETTI. Univ. Roma. *Atti accad. Lincei* [6], 7, 561-5(1928).—Mathematical, dealing with the perturbations produced on an atom by like atoms in close proximity to it, a phenomenon similar to resonance.

C. C. DAVIS

A simple method for measuring rotatory dispersion. ISAAC BENCOWITZ. Rockefeller Inst. *J. Phys. Chem.* 32, 1163-70(1928).—The chief difficulty in measuring rotatory dispersion lies in the lack of light sources of sufficient purity and intensity. In place of the expensive quartz Cd-Ga lamp of Bates, B. has used the continuous spectrum as a source. The light from a small elec. lamp is passed through a spectro-scope, the telescope end of which is replaced by a slit similar to that at the collimator end. From here the small patch of light enters the polarimeter, which further resolves the spectrum. With a narrow slit there is a point of extinction for which the mean rotation, α_c , of the different wave lengths transmitted depends on λ_c , the wave length of the "polarimetric" optical mean of the patch of light from the continuous source. In order to evaluate α_c and λ_c a calibration is made using the soln. to be tested and light from some monochromatic source. After substituting for the soln. a quartz test plate, the rotatory dispersion curve of which is known, the light from the spectro-scope is so adjusted that λ_c is equiv. to the wave length of the monochromatic source. The method is accurate to within 0.02° and may be used for any wave length, the rotation of which in quartz is known.

H. F. JOHNSTONE

The theoretical relation between infra-red and ultra-violet bands. R. T. BIRGE AND J. J. HOPFIELD. *Phys. Rev.* 30, 365-6(1927).—The frequency of infra-red (vibration-rotation) bands of a diatomic mol. can be calcd. from the measured frequencies of certain ultra-violet (electronic) bands correlated with the normal state of the mol. Thus for CO infra-red bands have been observed at 4.67μ , 2.35μ and 1.573μ , while from accurate data for the ultra-violet system the wave lengths of the infra red bands are calcd. to be 4.6672μ , 2.3475μ and 1.5744μ . The probable error in the calcd. values is about 1 part in 2000. Because of the greater resolution and sensitivity of the photographic plate, compared to infra-red recording app., this example encourages the hope of obtaining infra-red standards from measurements of ultra-violet radiation, in band spectra, as well as in the now familiar case of line spectra.

W. F. MEGGERS

Polarization of the resonance radiations of cadmium. PAUL SOULET. *Compt. rend.* 187, 212-4(1928).—Cd has 2 resonance radiations in the ultra-violet, viz. $1^1S_0 - 2^3P_1$ (3261 A. U.) and $1^1S_0 - 2^1P_1$ (2288 A. U.). In a previous note (C. A. 21, 3312) some preliminary results on the polarization of the first resonance line and on the influence of a weak magnetic field upon the polarization were given. These expts. are repeated with certain improvements. From measurements of 3261 A. U. an av. life of the Cd atom in the 2^3P_1 state is deduced as 2×10^{-6} sec. This orbit appears to be much more stable than the corresponding orbit of the Hg atom. Polarization of the 2288 A. U. line leads to the conclusion that the 2^1P_1 state has at least a double hyperfine structure, the more stable orbit having a life exceeding 10^{-6} sec. and the unstable one a duration of the order of 10^{-9} sec.

W. F. MEGGERS

The influence of different nuclei on the absorption spectra of organic compounds. J. E. PURVIS. *Proc. Cambridge Phil. Soc.* 24, 421-5(1928).—The effect of different nuclei on the absorption spectra of various compds. has been discussed in various papers (C. A. 20, 1030; 21, 2430). The problem is further investigated with the following substances: formanilide, phenylacetanilide, oxanilide, nitroso-*o*-cresol and nitroso-*m*-cresol, phenyl- α -naphthylamine, phenyl- β -naphthylamine, *ar*-tetrahydro- α -naphthylamine and *ac*-tetrahydro- β -naphthylamine. The general results show that in the phenyl derivs. of the 2 naphthylamines the introduction of the C_6H_5 group produces an addnl. band; that in the *ar*- and *ac*-hydrogen derivs. of these 2 compds. the type of absorption is controlled by the satd. or unsatd. condition of each constituent ring; that in the cresols the introduction of a NO group produces color; and that in the anilides the position of the typical absorption of aniline is destroyed, and it is replaced by a band due to a C_6H_5 group.

W. F. MEGGERS

Width of the lines of the Balmer series. MILE. M. HANOT. *J. phys. radium* [6], 9, 156-69(1928).—See C. A. 22, 3093.

H. G.

Some experiments on the continuous spectrum of hydrogen. YUTAKA TAKAHASHI AND YOSISIGE HUKUMOTO. *Science Repts. Tôhoku Imp. Univ.* [1st ser.], 17, 675-8(1928).—The effect of temp. on the continuous spectrum of H was studied by comparing the intensities of the spectrum emitted by a discharge tube cooled with liquid air and the spectrum of the same tube at room temp. The continuous spectrum was enhanced, at least in the region of wave lengths greater than 2300 A. U., while the intensities of

the lines belonging to the secondary spectrum and Balmer's series were reduced. (Cf. C. A. 21, 3829.) W. F. MEGGERS

Studies in the infra-red region of the spectrum. I. Description of prism spectrometer and apparatus. ROBERT ROBERTSON AND J. J. FOX. *Proc. Roy. Soc. (London)* A120, 128-48(1928). **II. Calibration of prism spectrometer; general procedure; and preparation of pure ammonia, phosphine and arsine.** ROBERT ROBERTSON, J. J. FOX AND E. S. HISCOCKS. *Ibid* 149-60. **III. Infra-red absorption spectra of ammonia, phosphine and arsine.** ROBERT ROBERTSON AND J. J. FOX. *Ibid* 161-89. **IV. Discussion of absorption bands of ammonia, phosphine and arsine.** *Ibid* 189-210.—For a projected investigation on the rate of decompn. of an explosive gas, AsH_3 , it became necessary to know its absorption in the infra-red spectral region. Interest in the absorption spectrum of AsH_3 led to the exploration of the same region for PH_3 and for NH_3 . A series of 4 papers describes (I) the app. and (II) methods adopted, (III) the results found for these 3 gases, together with (IV) a comparison of inter-relationships and their bearing on mol structure. The app. consisted of a Nernst filament as source, absorption tubes of 100 mm. or 450 mm. length, a Hilger No. 2 infra-red spectrometer with either a rock-salt, quartz or fluorite prism, a 20-element Bi-Ag thermopile and a Paschen galvanometer. The absorption spectra of NH_3 , PH_3 and AsH_3 in the interval 1μ to 17μ are described in tables and curves, and some of the bands are resolved into P, Q and R branches. From the fine structure of certain bands the mean moment of inertia J, for the NH_3 mol is found to be 2.88×10^{-40} g. per sq. cm. and the radius of gyration 0.82×10^{-8} cm. For PH_3 these consts. are 4.78×10^{-40} g. per cm. and 1.025×10^{-8} cm., resp., while for AsH_3 there are two values of each depending on which band they are derived from; the moments of inertia are 6.51×10^{-40} g. per sq. cm. and 5.53×10^{-40} g. per sq. cm., the corresponding radii of gyration are 1.165×10^{-8} cm. and 1.07×10^{-8} cm. W. F. MEGGERS

The time intervals between the appearance of spectral lines in the spectra of alkali and alkaline-earth metals. GORDON L. LOCHER. *J. Optical Soc. Am.* 17, 91-101 (1928).—By the method of Beams and others, the time intervals between the appearance in spark discharge spectra of about 50 lines of Na, Li, Ca, Ba, Sr, Mg, Cd, Zn and N were measured to det. if there was any relation between these times and the nature of the lines or the positions of the elements emitting them in the periodic table. The time intervals for different lines varied from zero to about 2×10^{-8} sec. Most of the lines appeared to be emitted at the very beginning of the discharge, before the potential across the spark gap had dropped appreciably. There did not appear to be any definite relation between the time intervals and the nature or origin of the lines. A variation of the time intervals with the amt. of inductance was observed; the times were independent of the other elec characteristics of the circuits. W. F. MEGGERS

Regularities in the spark spectrum of hafnium (Hf II). WM. F. MEGGERS AND BOURDON F. SCHRIBNER. *J. Optical Soc. Am.* 17, 83-90(1928).—Assuming that enhanced lines which are developed with great intensity in the arc as well as in the spark spectrum must involve low-energy states of the ionized atoms, the relative values of 16 low levels combining with 27 higher energy states, have been established. These combinations account for 206 lines of the Hf II spectrum. Although it is impossible without Zeeman effects to assign all the quantum nos. to each level it appears likely that the normal state of the Hf atom is represented by a $2D$ spectral term arising from the electron configuration d^{2s} . W. F. MEGGERS

The band spectrum of water vapor. III. DAVID JACK. *Proc. Roy. Soc (London)* A120, 222-34(1928).—In previous papers (cf. C. A. 21, 3157; 22, 2109) details were given of bands in the spectrum of H_2O vapor, including the arrangement of the band 2608 A. U. and 8428 A. U. into P, Q and R branches, and measurements of a series of singlet lines lying close to the head of the band 2811 A. U. The advances which have recently been made in the theory of band spectra throw some light on their structure; in the present paper the new methods are applied to the analysis of the water vapor bands. These bands can be interpreted as arising from transitions between 2S and 2P levels; the 2P levels being double while the 2S levels are probably rotationally single. The P and R main branches are due to transitions, 1 A to 1 B, and 2 A to 2 B, while the Q branches show "crossing over," 1 A to 1 A and 2 A to 2 A. Other combinations give rise to satellites, in some of which the σ -selection rule does not hold. The most striking feature exhibited by these bands is the presence of a singlet branch for which the combination principle definitely indicates a transition of two units in j_k . It is therefore, concluded that, although the j -selection rule, $\Delta j = \pm 1, 0$ probably holds rigidly, the other selection rules (j_k and σ) are only an expression of the most probable transitions and cannot be taken as final. W. F. MEGGERS

The Zeeman effect in the band spectrum of helium. W. E. CURTIS AND W. JEVONS. *Proc. Roy. Soc. (London)* A120, 110-27(1928).—The Zeeman effects of the He band spectrum have been investigated in fields up to 20,000 gauss with an 8-foot concave grating and with a Fabry-Perot 1-cm. étalon crossed with a const.-deviation glass prism spectrograph. The ranges of wave lengths investigated with the grating were 4758-4365 Å. U. and 4162-3626 Å. U. while the range covered by the prism spectrograph was 5000-4300 Å. U. Although none of the magnetic components was fully resolved, a great many instances of line broadening have been observed, and some information as to the polarization of the components has been obtained by means of a double-image prism. With those bands which are due to transitions between S and P electronic states the results are in qual. agreement with theoretical predictions. The effects, i. e., widths of patterns, decrease rapidly with increase of rotation, and the polarization of the outer components is opposite in character for Q and for P and R type branches.

W. F. MEGGERS

The absorption spectra of solutions of cobalt chloride, cobalt bromide and cobalt iodide in concentrated hydrochloric, hydrobromic and hydriodic acids. W. R. BRODE AND R. A. MORTON. *Proc. Roy. Soc. (London)* A120, 21-33(1928).—In an earlier paper (cf. *C. A.* 22, 1907) the selective absorption in the spectral interval 600 to 710m μ of CoCl₂ in concd. HCl was shown to consist of a no. of superimposed, similarly shaped absorption bands. The frequency values at which these component bands exhibited a max. of absorption corresponded with integral multiples of a common or fundamental frequency, 12.28 f. (= fresnel = vibrations ÷ sec. $\times 10^{13}$). The same app. and method have now been used to extend the observations to 400m μ ; the fine structure observed in this region is a continuation of that previously found for CoCl₂ in HCl. The absorption of CoBr₂ in HBr has been detd. throughout the visible spectrum, and the curve has been analyzed into a series of component bands, the centers of which are multiples of the frequency difference, 11.70 f., between the bands. The absorption spectrum of CoI₂ in HI, between 500 and 900m μ has been detd. by a combination of visual and photographic methods, and has been analyzed into a series of component bands, the centers of which are multiples of the frequency difference, 10.79 f., between the bands. An increase in the mol. wt. of the cobalt-halide complex causes a decrease in the frequency difference. The similarity of the curves indicates a similar constitution for the 3 cobalt-halide complexes investigated.

W. F. MEGGERS

The theory of the Ramsauer effect. J. HOLTSMARK. Univ. København. *Naturwissenschaften* 16, 614-5(1928).—The treatment of the Ramsauer effect previously given (C. A. 22, 1273) is compared with that of Ehrenfest and Rutgers (*Naturwissenschaften* 16, 184(1928)) and is shown to be analogous to Rayleigh's theory of line gratings as well.

B. J. C. VAN DER HOEVEN

Interference of light quanta. A. PROCA. *J. phys. radium* [vi], 9, 73-80(1928).—Theoretical. If time is taken as one of the coördinates in developing the quantum theory, it is found that quanta must be coherent.

B. C. A.

The spectrum of ionized sodium. F. H. NEWMAN. Univ. College of the Southwest of England. *Nature* 122, 97(1928); cf. *C. A.* 22, 1099.—Several pairs of wave-no. differences in Na II previously reported by N. are interpreted on the term scheme given by Laporte (C. A. 22, 2887), and it is predicted that others correspond to differences between s', d and d' terms. The series of Na II should resemble those of Ne I, but more exptl. data in the Schumann region will be needed for a complete analysis.

F. A. JENKINS

Scattering of light in dispersed systems of high concentration. G. I. POKROVSKII. *Z. Physik* 46, 753-8(1928).—It is shown that for dispersed systems of high concn the intensity, I_d , of a beam after scattering by a thin layer is expressed by the equation $I_d = I_0[1 - e^{-(a\psi/\theta)}]$, where ψ and θ are quantities that can be calcd. from the n of the medium and from the relative n of the dispersed phase, a is a constant and I_0 the incident intensity. Values calcd. in this way agree fairly well with Woronkoff's data for silk fibers dispersed in various media.

B. C. A.

The quantum theory of scattering and dispersion. ADOLF SMEKAL. *Naturwissenschaften* 16, 612-3(1928).—Referring to a previous article (C. A. 18, 2834) predicting the possibility of wave-length shift of light scattered by excited mols., S. now points out the first exptl. confirmation in the Raman effect (C. A. 22, 1907). It is considered a new argument in favor of the profound analogy between the effects of electrons and of light quanta on atom systems; in the Raman effect an analogue of second-order collisions is found.

B. J. C. VAN DER HOEVEN

The spark potential of pure gases at low pressures. KURT ZUBER. *Naturwissenschaften* 16, 615-6(1928).—By assuming that n_0 positive ions liberate one electron from

the cathode on impact, Townsend's equation gives $\ln n_0 = \pi c_1 e^{-c_2 \pi/V}$ for $\pi = pL$, p pressure in mm. Hg, V potential difference between electrodes at distance L mm., c_1 and c_2 gas consts. For $0.8 < (\pi/\pi_{\min.}) < 7$, the V values for N_2 follow the equation for n_0 const. If $c_1 = k/\Delta_0 \ln n_0$, the Δ being the mean free path of electrons at pressure of one mm., it follows that $\pi_{\min.} = (\Delta_0/k) \ln n_0$ with k for H_2 or N_2 0.453 or 0.455, resp. For a mean velocity of the electrons of A volts $c_2 = (P - A)/\Delta_0$ due to elastic collisions; A is found for H_2 at 5.1 to 6.2 v., for N_2 5.2 to 6.2 v., depending on the P value.

B. J. C. VAN DER HOEVEN

The first spark spectrum of krypton. P. K. KICHLU. Science College, Patna. *Naturwissenschaften* 16, 546(1928) (In English); cf. C. A. 22, 27.—From the work of Abbink and Dorgelo (C. A. 22, 1540) K. has come to a complete analysis of the first Kr spark spectrum, accounting for 200 lines. The lowest states are 3P terms, originating from an electron configuration of $5N_2$; they combine with 4P , 3P , 2D , 2S from $4N_2O$.

B. J. C. VAN DER HOEVEN

A novel effect of light scattering in crystals. G. LANDSBERG AND L. MANDELSTAM. Univ. Moskau. *Naturwissenschaften* 16, 557-8(1928).—A quartz crystal was illuminated by a Hg arc light beam. The normal spectral lines (quartz spectrograph) of the light scattered perpendicular to the incident ray (2 to 14 hrs. exposure) have for 2 different quartz pieces distinct companion lines of slightly longer λ , one sharp, and indications of 2 or 3 more. These lines are not absorbed by an interposed quartz vessel filled with Hg vapor. For λ 2536 was found $\Delta\lambda = 30$, for 3126 $\Delta\lambda = 47$, for 3650 $\Delta\lambda = 63$. The frequencies found can be explained by assuming excitation of a $\lambda = 20.7\mu$ ultra-red proper frequency of the quartz. In calcite the same thing was found with $\lambda = 9.1\mu$ for the ultra-red frequency.

B. J. C. VAN DER HOEVEN

Characteristics of the neutral and of the singly and doubly ionized spectra of cerium. ARTHUR S. KING. *Phys. Rev.* 30, 366(1927).—By comparing the arc and spark spectra of Ce with that of the elec. furnace it was possible to distinguish between the ionized at. spectrum and the spectrum of the neutral atom. The latter for which the furnace is the only effective source, has been to a large extent unrecognized. A condensed spark discharge gave a large no. of doubly ionized lines, of which only the strongest group has been previously measured.

W. F. MEGGERS

Excitation of Cu II spectrum by positive neon ions. O. S. DUFFENDACK AND J. G. BLACK. Univ. of Michigan. *Phys. Rev.* 29, 925(1927).—Low-voltage arcs were maintained in mixts. of A and Cu and Ne and Cu in a suitable furnace and the spectra were photographed with a quartz spectrograph. The mixt. with A failed to produce spark lines but in the Ne mixt. the lines were strongly developed. The lines from the higher level were considerably more intense, relative to those from the lower level, than they are in the ordinary spark.

W. W. STIFLER

Infra-red spectrum of ammonia. W. F. COLBY AND E. F. BARKER. Univ. of Michigan. *Phys. Rev.* 29, 923(1927).—The absorption band of NH_3 at 10μ was analyzed into 2 overlapping bands with zero branches at 10.3μ and 10.7μ . About 12 lines were observed in each branch. Other NH_3 bands previously reported are interpreted.

W. W. STIFLER

Infra-red reflection spectra of some carbonates. E. K. PLYLER. Univ. of North Carolina. *Phys. Rev.* 29, 923(1927).—On reflection from the surface of clear calcite maxima were found at 6.36μ , 6.54μ and 6.62μ . These are ascribed to isotopes of Ca and suggest 3 isotopes instead of 2. The reflection spectra for $FeCO_3$ and for dolomite each showed 2 maxima.

W. W. STIFLER

Light absorption of some salts and its explanation. A. HANTZSCH. *Z. physik. Chem.* 134, 453-5(1928).—Solid alkali halides are transparent throughout the ultra-violet, while solns. of the bromides absorb considerably and solns. of the iodides strongly; the explanation suggested is that in the solids the halogen ions are completely satd., whereas in soln. they are hydrated. Solns. of the chloride, if purified to optical constancy, are transparent in the ultra-violet. SnI_4 gives an orange soln. in ether, no change in color from the solid occurring, while red HgI_2 gives a colorless soln. in ether. The difference is due to the fact that solid SnI_4 is a monomol. pseudo salt and dissolves unchanged, while solid HgI_2 is an assocd. pseudo salt and dissolves as a monomol. substance.

W. WEST

Ultra-violet absorption and emission spectra of carbon monoxide. J. J. HOPFIELD AND R. T. BRIDGE. Univ. of California. *Phys. Rev.* 29, 922(1927).—The pressure of CO in the receiver of the spectrograph was varied gradually from 0.05 to 850 mm. The spectrograms thus obtained made it possible to identify 9 absorption systems between 920 A. U. and 2064.5 A. U., representing transitions from the normal level to all the

excited electron levels previously known and to 4 new levels, viz., 58,927, 92,923*, 99,730 and 105,270 cm.⁻¹. These new data permit many tests of the combination principle. W. W. STIFLER

Light absorption of liquefied gases. F. G. BRICKWEDDE AND W. A. MACNAIR. Bureau of Standards. *Phys. Rev.* **29**, 916(1927).—The absorption spectra of liquid O, N and H from 2000 to 6500 Å. U. were photographed with a quartz spectrograph. A no. of new bands were found in the O spectrum. There were no absorption bands in the N spectrum throughout the entire range and none in the H spectrum between 2000 and 3800 Å. U. W. W. STIFLER

Conditions of emission of forbidden lines. A. S. EDDINGTON. *Month. Not. Roy. Astron. Soc.* **88**, 134-8(1927).—Possibilities are discussed to account for the brightness of forbidden lines in nebulas in comparison with ordinary lines. It is suggested that the stimulating radiation must be so weak that the atom is unlikely to absorb a quantum during the full duration of the metastable state. A similar explanation would hold if nebular light were due to ordinary temp. collisions, but the latter is regarded as improbable. It is shown to be unlikely that the coronium spectrum can consist of forbidden lines. R. C. A.

Shading of band spectra and degeneration. H. LUDLOFF. *Naturwissenschaften* **16**, 611-2(1928).—Two neutral atoms can bind each other either by the spatial distribution of their charge "clouds" and mutual polarization or by exchange and degeneration of their electron systems. The sum total of the effects detrs the energy of the bond. Which one of the bond types predominates can be seen from the shading of some band spectra. Shading to the red signifies that the valence electron promotes the bond (the lower energy level has smaller nucleus distance and higher bond energy); violet shading indicates disturbance of the bond by the valence electron. Examples of both cases, H₂ for red shading, MgH, CaH, ZnH, CdH, HgH for violet shading, are discussed on a basis of their quantum mechanics. In the first case the Pauli principle leads to an attractional effect, the result of the mutual interaction; in the second case to repulsion. The 2 types often correspond to even and odd electron mols., resp. B. J. C. VAN DER HOEVEN

The ultra-violet band spectra of nitrogen. R. T. BIRGE AND J. J. HOPFIELD. Univ. of Calif. *Phys. Rev.* **29**, 356(1928).—Previous work by the same authors has been extended to include 60 bands between λ 1205 and λ 2025. The assignment of this system to NO is not justified. L. D. R.

Multiplets in the spectra of Cr (III) and Mn (III). R. C. GIBBS AND H. E. WHITE. Cornell Univ. *Phys. Rev.* **29**, 917(1927); cf. *C. A.* **21**, 1063, **22**, 1276. The systematic arrangement of radiated frequencies arising from the transition of an electron from a $4p$ to a $4s$ orbit in the presence of 0, 1, 2, 3, etc., $3d$ electrons is extended for the elements of the first long period from K to Cu. The Mosely diagrams for the deepest lying terms give very straight lines and reveal a regular and systematic displacement in passing from one isoelectronic system to another. W. W. STIFLER

The alleged luminosity of liquids on adiabatic compression. G. TAMMANN AND C. KRÖGER. Univ. Göttingen. *Z. anorg. allgem. Chem.* **171**, 364-6(1928).—The luminosity of liquids and gases unter pressure, as shown by Desaignes and Heinrich, is not due to a compression of enclosed air bubbles, according to expts. In one series of expts., in which air bubbles were held in the compressed liquids, castor oil, e. g., was luminous in 46 cases, and non-luminous in 94 cases. In another series in which air bubbles were absent, castor oil was non-luminous in all (33) cases. Heinrich states that the luminosity was greatest at the lower end of vertical compression tubes where the no. of air bubbles must be very small. A. J. CURRIER

The afterglow of mercury resonance radiation on addition of nitrogen. G. RAMSAUER. *Astrophysik. Observat., Berlin. Naturwissenschaften* **16**, 577(1928).—The resonance luminescence λ 2537 of Hg vapor in a 5-cm.-long quartz vessel at room temp., with N₂ addn. up to 8 cm. pressure, excited by Hg light, continued for $1/300$ sec. after excitation, decreasing in intensity with time. No such effect was found without N₂. For the most favorable conditions (cooled lamp, 4 mm. N₂), the line appeared on a photographic plate after $1/2$ -hr. exposure (Fuess spectrograph, Becquerel phosphoroscope). The effect is explained by assuming that metastable excited Hg atoms in 2^3P_0 condition, produced by the N (Wood, *C. A.* **20**, 17), are brought back to 2^3P_1 by impact with N₂ (Foote, *C. A.* **21**, 3555) and from there emit resonance radiation while returning to 2^3P_0 . The time period of radiation has to be of the order of that of the life of the metastable state (Dorgelo, *C. A.* **20**, 1173). The theory was confirmed by introducing an amt. of H₂ in the Hg tube sufficient to reduce the resonance line to $1/4$ of its previous strength; the H₂ destroys the metastable Hg state; simultaneously all afterglow dis-

appeared (less than $1/2000$ sec.). A Br filter in the path of the exciting light does not influence the effects.

B. J. C. VAN DER HOEVEN

Phosphorescent aluminum nitride, activated by silicon. ERICH TIEDE, MAX THIMMANN AND KARI SOMMER. *Zeits. Physik.* **B**, 612, 1563-75(1927). In an analogous manner to the activation of BN by C, AlN becomes phosphorescent when it contains a small quantity of Si. Two methods of prepg. activated AlN are described. In one, finely divided Al to which has been added pure SiO_2 or which contains up to 10% SiO_2 , is heated at 1300° in a Mo-lined Ni tube while a stream of NH_3 is passed over it. In the other method, AlCl_3 is purified by sublimation and then converted by the action of NH_3 into the addn. compd. $\text{AlCl}_3\cdot\text{NH}_3$. This is placed in a specially constructed app. in which it can be vaporized by heating to about 400° , the vapor coming in contact with a W spiral heated to about 1000° , N being passed through the app. at the same time. The N is previously bubbled through SiCl_4 to provide the necessary Si. The AlN obtained is yellowish white, hard and shows a pronounced blue phosphorescence. The activating effect commences with a Si content of about 0.5%, is a max. at about 5% Si and then slowly decreases. Analysis of the emission shows it to consist of very short-wave-length radiation (under 300μ), lying chiefly in the blue zone, and showing 3 bands, analogous to BN. AlN phosphorescence is excited best by the Fe arc and then the Hg vapor lamp. No other element possesses the property of activating AlN. BN and AlN are distinguished from the sulfide phosphors in the fact that they are activated by non-metals while the sulfide phosphors are activated by extremely small quantities of the heavy metals. X-ray examn. of the AlN phosphor shows its crystal structure to be of the diamond type, similar to that of Si, and only when this structure is found is the material phosphorescent. H. S.

Active nitrogen. V. The decay of the nitrogen afterglow. ERIC JOHN B. WILLEY. *J. Chem. Soc.* **1928**, 1620-9; cf. *C. A.* **22**, 915.—Investigations are made to det. if the total N_2 pressure greatly influences the N-glow decay process. Gas flow speeds up to 3500 cc. hr. and pressures to 10 mm. give brilliant glows. An r.m.s. current of 20 milliamp. is used in the discharge, 4 quart-size Leyden jars being in parallel with it. Intensities of glow arc measured with an Eastman colorimeter (*Nature* **118**, 30(1926)). From measurements of the decay in the observation tube at varying flow speeds and pressures, curves of the sq. root of the glow intensity against the time (distance along the tube) are plotted. With times so expressed, comparable results are obtained only when the slopes of these lines are multiplied by $\frac{\text{gas pressure}}{\text{flow rate}}$. Tables of cor. slopes

show that the decay rate increases with the gas pressure. Graphically it is seen that $\log S/\log p = 3$ (slopes vary as the gas pressures cubed). These expts. indicate that the decay of the N after-glow is of the 5th order between 2 and 8 mm. pressure. Calcns. show that if the reaction, in reality, is bimol., the concn. of the glow-producing system (assuming it to be at.) is $10^{-5} - 10^{-6}$ of the chemically active N present under the same conditions. W. suggests, to overcome this difficulty, that the decay process consists of an initial slow ternary collision ($2\text{N} + \text{N}_2 = 2\text{N}_2$), followed by 2 rapid binary impacts, neutral N_2 being involved as one of the two reactants. The neg. temp. coeff. is accounted for by this theory, which also renders probable the independence of glow and chem. activity under certain circumstances. If one at least of the decay stages gives an excited mol. of $10^{-6} - 10^{-8}$ sec. life, then the order of the decay process, and the chem. and luminous phenomena connected with active N most probably depend on the total N_2 pressure. J. BALOZIAN

Nature of the nitrogen afterglow. A. G. WORTHING. Nela Research Laboratory and Univ. of Pittsburgh. *Phys. Rev.* **29**, 907-8(1927).—Three 15-cm. glass bulbs, symmetrically joined by large glass tubing, were filled with N_2 at 1 to 5 mm. pressure. The effects observed under various conditions of discharge are described. It seems probable that either the afterglow carriers or some of the agents active in the production of these carriers are electrically charged. The theory that the afterglow is due to impacts of neutral unexcited atoms and mols. is not supported by these observations. W. W. STIFLER

Chemiluminescence by oxidation of dyes by ozone. N. N. BISWAS AND N. R. DHAR. Allahabad Univ., India. *Z. anorg. allgem. Chem.* **173**, 125-36(1928).—Chemiluminescence due to oxidation of various fluorescent and non-fluorescent dyes by ozonized O has been studied. The light phenomenon is stronger in solns. other than water and depends on the solvent. O alone has no effect. A photographic plate is not affected by the action and a quartz spectrograph, calibrated by a He tube, was therefore used to measure the effect. The dyes studied were eosin, uranin, safranin,

neutral red, rhodamine B, rhodamine B. J. N. N., thioflavine, cartharamin, erythrosine and esculin. Reducing agents such as terpine, hydroquinone sodium sulfite, nicotine, brucine, etc., suppress the illumination. The relation between chemiluminescence and fluorescence is discussed from the viewpoint of activation of the mol. It is believed that when Na and Cl react in the presence of Hg atoms of the latter are absorbed in the activated state. This would account for the Hg line 2537 Å. U. produced. A similar explanation would explain activation of H on Pt and Pd surfaces. The decompn. of ozone by a suppression of illumination is not always the reason for the retarding action in chemiluminescence.

RAYMOND H. LAMBERT

The chemistry of band spectra. R. Mücke. *Naturwissenschaften* 16, 521-9 (1928).—A review including the constitution of "spectrographic" mols., energy of chem. bonds, distances of atoms and vibration frequencies, dissocn. energy, interpretation of reaction processes, etc., as found from the study of band spectra. Several tables are given of vibration frequencies of hydrides, oxides, nitrides, halides and mols. of elements, also one of the dissocn. energy of 20 compds. B. J. C. VAN DER HOEVEN

The interpretation of diffuse molecular spectra. Experiments on the photochemical decomposition of ammonia. K. F. BONHOEFFER AND L. FARKAS. Kaiser Wilhelm-Inst., Berlin-Dahlem. *Z. physik. Chem.* 134, 337-44 (1928).—V. Henri interprets those mol. electronic-vibrational spectra which show no rotational fine structure as indicating a state of "predissociation" in which the mol. passes to an excited state unquantized with reference to rotation. B. and F. see rather a Heisenberg resonance phenomenon, in which an excited mol., instead of returning to the normal state with the emission of radiation, spontaneously decomposes, the very short life in the excited state causing an abnormal broadening of the rotational lines and consequent disappearance of fine structure. Evidence for this view is seen in expts. on NH_3 , which, in spite of its small moment of inertia, shows in the far ultra-violet a system of partial bands without fine structure (cf. Liefson, *C. A.* 20, 1951). (1) NH_3 streaming through a discharge tube at sufficiently high velocity gave no emission spectrum, despite the low excitation potential. Conclusion: The NH_3 mol. is really excited, but does not radiate. (2) At pressures of a few mm. and slower stream, the NH_3 bands were obtained in absorption against a continuous background on passing a discharge through the tube. (3) An attempt to observe fluorescence in NH_3 gave a neg. result, again in accordance with a very short life period. (4) NH_3 was decompd. rapidly at 0.001 mm. Hg by radiation in its absorption region suggesting spontaneous decompn. The low quantum yield observed by Warburg and by Kuhn must be due to a reversal of the decompn. In general, predissocn. spectra will exist when the absorbed quantum is greater than the energy required to dissoc. the mol. at the part linked by the electrons concerned in the absorption.

W. WEST

The quantum yield on photolysis of silver chloride. P. FELDMANN. Bayer. Akad. Wissensch., München. *Naturwissenschaften* 16, 530-1 (1928).—The photochem. yield of decompn. of AgCl by 365μ light was measured on pure AgCl , suspended in water, the Cl being detd. potentiometrically (Lange and Schwartz method with NaNO_2 addn.). The energy irradiated was measured with a standard thermopile. The quotient (Cl atoms)/(quanta) was found from the av. of 8 expts. to be $0.86 \pm 2\%$. Further irradiation of exposed AgCl gives considerably lower values, the difference of the quotient from 1 is therefore ascribed to inactive absorption of some quanta by free Ag atoms. The result agrees with that of Eggert and Noddack (*C. A.* 19, 2452) by Ag detn. in AgCl gelatin.

B. J. C. VAN DER HOEVEN

Photochemical reactions. III. Influence of polarized radiations on certain photochemical reactions. S. S. BHATNAGER, H. L. ANAND AND A. W. GUPTA. *J. Indian Chem. Soc.* 5, 49-57 (1928).—Polarized and heterogeneous light of equal intensities have the same effect on the photochem. reactions occurring between diammonium oxalate and HgCl_2 and on the decompn. of alk. H_2O_2 . From previous results (*C. A.* 19, 3429; 20, 870) it is concluded that polarized light possesses a selective effect only in heterogeneous systems.

B. C. A.

The products of the photochemical decomposition of hydrogen azide. ARNOLD O. BECKMAN AND ROSCOE G. DICKINSON. Calif. Inst. Technology. *J. Am. Chem. Soc.* 50, 1870-5 (1928).—On brief illumination HN_3 gives a gas, non-condensable in liquid air, while on longer illumination a white solid, presumably ammonium azide (NH_4N_3) is formed. The photochem. threshold was certainly below $\lambda 2400$, and light absorption of gaseous HN_3 was shown to set in at $\lambda 2200$ Å. U. The quant. extent of decompn. and identity of the products of decompn. were established by measurements with quartz-fiber and McLeod gages. From expts. with long times of illumination,

the formation of N_2 , H_2 and NH_3 , occurred simultaneously. The mol. wt. of HN_3 detd. by pressure measurements is 43.6 ± 2.1 . H. R. MOORE

Experimental technic of photochemistry. V. Reflection losses in the optical system of the higher ultra-violet monochromatic illuminator. H. N. RIDYARD AND D. W. G. STYLER. *J. Phys. Chem.* **32**, No. 6, 861-7(1928).—The reflection of the Hg lines by the mirror in the Hilger ultra-violet monochromatic illuminator has been studied experimentally. The reflection losses at the various quartz surfaces in this instrument have been calcd. From the figures obtained, the total transmission of the Hg lines has been calcd., together with factors to reduce results obtained with the instrument to a common base. Wave lengths in μ : 254, 265, 313, 365, 405, 436, 546, 579; transmission in %: 43.1, 44.6, 46.2, 47.5, 47.5, 48.0, 48.4, 48.5; factors: 1.13, 1.09, 1.05, 1.02, 1.02, 1.01, 1.00, 1.00. A. L. HENNE

The photochemical action of x-rays of different wave lengths. R. GLOCKER AND O. RISSÉ. *Techn. Hochschule. Stuttgart. Z. Physik* **48**, 845-51(1928).—The decompn. of H_2O_2 and $K_2S_2O_8$ in $M/600$ aq. soln. produced by x-rays of wave lengths 0.19, 0.56, 0.71, 1.54 A. U. was investigated. The quantity of substance decompd. is proportional to the amt. of x-ray energy converted to electronic energy, independent of the wave length. For the complete decompn. of 1 mol. of H_2O_2 in $M/600$ aq. soln., 70,000 cal. of electronic energy is required; for $K_2S_2O_8$ the quantity is 2.45 times greater. Not only the electrons liberated from the atoms of dissolved substance, but all the electrons produced in the soln. are effective. The Einstein photochem. equiv. law is inapplicable for x-rays, because of the great no. of secondary electrons produced besides those primarily liberated by the radiation. W. WEST

Photographic action of H-rays from paraffin and atom fragments. MARIETTA BLAU. *Z. Physik* **48**, 751-64(1928).—It has already been shown that an α -particle obliquely incident on a photographic plate produces a track appearing under the microscope as a row of points. H particles produced by the action of α -particles on paraffin or by at. disintegration show similar tracks. While for α -particles, every grain in the path is affected, the distance sepg. the blackened grains produced by H-particles shows that not every grain is changed; the ratio of the av. distance between the points for α - and for H-particles of the same velocity is 0.64, and for faster H-particles 0.51. The photographic method is not suitable for quant. measurements in at. disintegration because of the unfavorable yields caused by the necessary oblique incidence; and because H-rays of a residual range of less than 2.8 cm. are only partly observed, and those below 1.5 cm. residual range not at all. The method is suitable for the qual. recognition of H-particles, since in the absence of α -particles, a single point track is objective proof of H-particle. W. WEST

Combination of hydrogen and oxygen by electric discharges and x-rays. ROGERS D. RUSK. North Central College. *Phys. Rev.* **29**, 907(1927).—The results obtained in the low-voltage arc indicate that combination occurs chiefly at or near the cathode. In the Geissler tube and the electrodeless discharges and with x-rays the combination seems to be a matter of gaseous collision. The results agree with the idea that combination is proportional to the no. of ions present. W. W. STIFLER

The absorption spectra of nitric oxide. MAURICE LAMBREY. *Compt. rend.* **187**, 210-2(1928); cf. *C. A.* **22**, 2325.—Two curves are published to represent the coeff. of absorption α of NO as a function of the wave length, special details being given for 2 doublets, 2267.85 A. U., 2261.5 A. U. and 2153.75 A. U., 2148.15 A. U. W. F. M.

Spectrochemistry and constitution of azoxy compounds. K. VON AUWERS AND P. HEIMKE. Chem. Inst. Marburg. *Ber.* **61B**, 1037-41(1928).—Homogeneous azoxy-compds. are most readily prepd. by oxidizing azo compds. with H_2O_2 . The following data, among others, are recorded for the homogeneous substances: azoxybenzene, d_4^{20} 1.1590, n_D^{20} 1.65103; *o,o'*-azoxytoluene, d_4^{20} 1.0548, n_D^{20} 1.57686; *m,m'*-azoxytoluene, d_4^{21} 1.1136, n_D^{21} 1.63345; α -*p*-bromoazoxybenzene, d_4^{20} 1.4068, n_D^{20} 1.64967; β -*p*-bromoazoxybenzene, d_4^{20} 1.4138, n_D^{100} 1.64497; α -*p*-ethoxyazoxybenzene, d_4^{20} 1.1082, n_D^{99} 1.62363; β -*p*-ethoxyazoxybenzene, d_4^{20} 1.1068, n_D^{100} 1.61348; *p*-ethoxyhydrazobenzene, d_4^{20} 1.0556, n_D^{100} 1.57491; *p*-phenetidine, d_4^{15} 1.0652, n_D^{15} 1.55715. Observations for certain compds. in quinoline are also given. The data strongly support the constitution assigned to azoxy compds. by Angeli. The behavior of *o,o'*-azoxytoluene is, however, exceptional and may possibly indicate the presence of a 3-membered ring. B. C. A.

Spectrochemical observations on azo compounds. K. VON AUWERS AND P. HEIMKE. Chem. Inst. Marburg. *Ber.* **61B**, 1030-6(1928).—Observations on Me and Et azoisobutyrate give the value $D = 3.179$ for the unconjugated—N:N—group,

which is in good agreement with the datum $D = 3.266$ deduced by Lochte, Noyes and Bailey (*C. A.* 17, 267) from expts. on azoisopropane. Observations on purely aromatic azo compds. are hampered by the difficulty of obtaining homogeneous products by reduction of nitro compds. in alk. soln. since these usually contain varying amts. of azoxy substances; homogeneous azo derivs. are obtained by treating pure hydrazo compds. with the necessary amt. of Br. The color of the substances usually inhibits measurement except with the H_{α} and sometimes the yellow He line. In cases where the high m. p. of the compd. necessitates the use of a solvent, quinoline is found very serviceable. The sp. exaltations for azobenzene and its homologs are grouped closely round the mean value $+3.05$. This high value is due to the structure of the substances since the value of EF_n^{20} for the analogously constituted *m*-methylstilbene is $+3.1$; the twice-broken, treble conjugations $C \cdot CR \cdot C \cdot C \cdot CR \cdot C$ and $C \cdot CR \cdot N \cdot N \cdot CR \cdot C$ are therefore spectroscopically equiv. Entry of a hydroxyl or an alkoxy group into the azobenzene mol. invariably increases these exaltations, but the action of the groups is unequally strong and depends on their position. The following data, among others, are recorded for the homogeneous substances: Me azoisobutyrate, $d_4^{17.3} 1.0365$, $n_D^{17.3} 1.43335$; Et azoisobutyrate, $d_4^{18.9} 0.9932$, $n_D^{18.9} 1.42831$; phenylazoethane, $d_4^{21.9} 0.9628$, $n_D^{21.9} 1.53133$; azobenzene, $d_4^{78.1} 1.0362$, $n_D^{78.1} 1.62662$; *m*-methylazobenzene, $d_4^{17.6} 1.0658$, $n_D^{17.6} 1.64822$; *o,o'*-dimethylazobenzene, $d_4^{65.3} 1.0215$, $n_D^{65.3} 1.61804$; *m,m'*-dimethylazobenzene, $d_4^{66.2} 1.0123$, $n_D^{66.2} 1.61519$; *o*-methoxyazobenzene, $d_4^{100} 1.0728$, $n_D^{100} 1.62652$; *p*-ethoxyazobenzene, $d_4^{99.6} 1.0400$, $n_D^{99.6} 1.62355$; benzencazothymol, $d_4^{100.2} 1.0328$, $n_D^{100.2} 1.63169$; benzencazothymol ethyl ether, $d_4^{100} 0.9791$, $n_D^{100} 1.59345$; *n*-propyl *p* hydroxybenzoate, $d_4^{102.1} 1.0630$, $n_D^{102.1} 1.50503$; *n*-propyl anisate, $d_4^{100} 1.0054$, $n_D^{100} 1.47977$. Measurements are also recorded for certain of the compds. dissolved in quinoline, abs. alc., or propyl butyrate. The ethyl ether of benzencazothymol, m. 85° , has not been described previously.

4—ELECTROCHEMISTRY

COLIN G. FINK

Electrometallurgy of steel for foundry use. R. J. RICHARDSON. *Iron & Steel Canada* 11, 232-7 (1928).—A brief illus. review of different types of elec. furnaces. Characteristics are noted of: furnace linings; basic operation; removal of the elements; refining slags; acid practice; reducing acid conditions; time of heat; and a comparison of acid and basic elec. steel. The chief disadvantage of acid steel is the presence of occluded or dissolved oxides which with higher S causes rearing of the castings during contraction and possibly loss of mech. strength. Elec. conversion costs are higher in fuel, refractories and electrodes, while the converter uses more expensive scrap and has higher melting losses. A few test results are tabulated. The future of the elec. furnace depends upon: (1) the regularity of high-grade production; (2) the ability to cast thin sections without re-run; and (3) the lower % of rejected castings.

W. H. BOYNTON

The high-frequency induction furnace for chemical preparations above 1000° (ferrous oxide). C. N. SCHURTE and CHAS. G. MAIER. *Trans. Am. Electrochem. Soc.* 54 (preprint), 13 pp. (1928).—The use of the high-frequency induction furnace for

chem. preps. above 1000° involves many special problems of technic. Varieties of furnace equipment, including a simple type of *vacuum furnace* not hitherto described, are discussed. Some special types of *crucibles*, and methods of making them, are given in detail. New methods for the prepn. of FeO , using the induction furnace, are described. Miscellaneous items of technic, which may be helpful to those having to prep. chem. samples above 1000° , are included. C. G. F.

The consumption of electrodes in the electric furnace and its causes. A. TENIVELLA. *Met. ital.* **20**, 253-8(1928).—A review and discussion, dealing with the various conditions of operation of the elec furnace and the factors which lead to destruction of the electrodes. C. C. DAVIS

Observations relative to the control of a charge in the electric furnace. A. TENIVELLA. *Met. ital.* **20**, 205-10(1928).—A discussion of the best methods of operating an elec. furnace, including its inspection and repair, charging, the oxidizing period of the fusion, refining, control of the compn., control of the temp., pouring and the economic balance. C. C. DAVIS

Time switches increase usefulness of electric furnaces. JAMES FAULKNER. Commonwealth Edison Co., Chicago. *Elec. World* **92**, 368(1928).—The current is automatically switched on and the furnaces start operating several hours before the working day for the attendant begins. C. G. F.

Further data on operating cost of a platinum-wound electric furnace. EDWARD ORTON, JR., AND J. F. KREHBIEL. *J. Am. Ceram. Soc.* **11**, 685-6(1928); cf. C. A. **21**, 2849. C. H. KERR

The production and uses of beryllium. KURT ILLIG. *Trans. Am. Electrochem. Soc.* **54** (preprint), 11 pp (1928); cf. C. A. **22**, 938. —Although Wohler obtained metallic Be a hundred years ago, by reduction with K, it was not until recently that Stock and Goldschmidt produced the metal by the fused electrolyte (fluoride) method. Their method has been developed by the Beryllium Institute, and large masses of metal (150 g.) are now turned out commercially. Properties of certain new metal alloys are enumerated. C. G. F.

The effect of adsorbed gas on the contact resistance of carbon. ROBERT H. WRIGHT WITH MELVILLE J. MARSHALL. *Trans. Am. Electrochem. Soc.* **54** (preprint), 11 pp.(1928). —The effect of adsorbed gas on the contact resistance of C has been investigated, in the light of the hypothesis that adsorbed gas films on the C surface may be responsible for part of this contact resistance. The contact resistance of C filaments was measured, both in air and after outgassing at 1700° in a high vacuum. Curves were obtained showing the variation of resistance with pressure under these conditions. For contacts too light to be measured, much lower resistances could be obtained after outgassing. For intermediate contact pressures outgassing reduced the resistance to about $\frac{2}{3}$ of its original value. Heavy contacts showed about the same resistance for the 2 conditions. It is shown that this is in accordance with the theory proposed. C. G. F.

A voltaic hydrogen generator. W. CECIL GARDINER AND GEO. A. HULETT. Princeton Univ. *Trans. Am. Electrochem. Soc.* **54** (preprint), 9 pp (1928).—A H generator is described which is applicable for use when a slow, steady evolution of pure H is desired for a long time. The generator consists of an amalgamated Zn anode and a Pt black or Ni cathode in an electrolyte of NaOH contg. a little Ba(OH)_2 . The generator operates at full capacity on short-circuit, but may be controlled by introducing a variable resistance in the circuit. No impurities are introduced into the H when the generator is allowed to run on a short-circuit. The generator has been shown to give off O_2 -free H. The generator is designed to eliminate dead space. C. G. F.

Cathodic halogen. R. H. CLARK AND R. H. BALL. *Trans. Am. Electrochem. Soc.* **54** (preprint), 5 pp.(1928).—The electrolytic products of certain *N*-halogen compds., *N*-bromo- and *N*-iodo-succinimide and *N*-bromo-acetanide, in various org. solvents have been investigated. Measurements of the oxidizing power of these compds. support the belief that the halogens are positive. On electrolysis, with Ag electrodes, 1.5 cm. apart, the halogen deposited on the anode in all solvents used with the exception of acetonitrile. In this latter solvent the halogen from freshly purified $(\text{CH}_3\text{CO})_2\text{NBr}$ deposited wholly on the cathode. The halogen from $(\text{CH}_3\text{CO})_2\text{NI}$ and AcNHBr in the same solvent repeatedly deposited on both electrodes. C. G. F.

Conductivity of organic solvents. D. B. KEYES, SHERLOCK SWANN, JR., AND H. W. HOERR. *Trans. Am. Electrochem. Soc.* **54** (preprint), 7 pp.(1928).—The conductivities of several of the more common org. solvents, pure compds. and mixts. were measured. The d. c. method of cond. measurement was used, due to the fact that the Kohlrausch method was unsatisfactory on account of the low cond. of some

of the materials examd. The method described is satisfactory for detns. of conductivities of com. org. liquids.

Solvent	Cond. (reciprocal Int. ohm.-cm.) $\times 10^{-12}$ at 25°	Solvent	Cond. (reciprocal Int. ohm.-cm.) $\times 10^{-12}$ at 25°
1. Pentasol (com. Am alc.)	360,000	6. Toluene	49
2. Pentasol acetate (Am acetate)	1,600	7. Bu alc.	2,900,000
3. Isoamyl alc.	8,000	8. <i>tert</i> Bu alc.	280,000
4. Cellosolve (ethylene glycol monoethyl ether)	1,800,000	9. Et lactate	1,000,000
Cellosolve acetate (ethylene glycol monoethyl ether acetate)	47,000	10. Diethyl carbonate	910
		11. Et acetate 85%	320,000
		12. Et acetate 99 to 1	3,000
		13. Bu acetate 85%	16,000

Electroplating on aluminum and its alloys. HAROLD K. WORK. *Metal Ind.* (London) 33, 81-4, 105-8 (1928).—See C. A. 22, 1915, 2516. C. G. F.

Polarization and resistivity in nickel plating solutions. ROY L. DORRANCE AND W. C. GARDINER. *Trans. Am. Electrochem. Soc.* 54 (preprint), 9 pp. (1928).—With a Haring cell, the anodic and cathodic polarizations and resistivities of various Ni-plating solns. were measured at 17°. The anodic polarization was considerably reduced by the presence of chloride ion, although no appreciable difference is noted in the action of the metallic ion, K, Na, NH₄, Ni or Mg assocd. with the chloride ion. The effect of bromide ion is the same as that for the chloride ion, while the fluoride ion does not materially reduce anodic polarization. Measurements were also made on other recommended solns. H. G.

Nickel anodes and the acidity of the solution. R. G. SUMAN. *Metal Ind.* (N. Y.) 26, 350 (1928).—A short summary of an extended expt. with Ni anodes as to *p_H* change. The object of the expt. was: (1) to det. why a Ni soln. tends to become either acid or alk.; (2) thence, to discover a remedy; (3) to ascertain the proper amt. of chlorides; and (4) to furnish a good Ni soln. for electrotyping. The reaction varied with the compn. of the anodes. The soln. was used in Pb-lined tanks and contained 9 oz. (255 g.) single Ni salts, 0.7 oz. (19.8 g.) NH₄Cl, and 1 gal. (3.8 l.) water. A 6.1 *p_H* soln. is about the most efficient for Ni plating. A graph gives detailed observations of the expt. C. G. F.

Automatic cadmium plating. FAY LEONE FAUROT. *Iron Age* 122, 341 2 (1928).—A brief description of the automatic Cd plating equipment at the Fordson plant for plating Model A brake shoes. Four main tanks are: (1) the elcc. cleaning soln.; (2) the first water rinse; (3) the Cd plating tank; and (4) the hot water cleaning or rinsing tank. The parts in groups of 10 are hung on the suspension frames which are placed on conveyor hangers in pairs. To get from the loading position and from tank to tank, a slowly revolving telescopic arm picks the hanger off the supporting conveyor fingers, lifts it straight up, carries it forward to its elevated position, and lowers it again on the forward moving conveyor and the work is submerged in the next soln. The cleaning soln. contains Na₂PO₄, soda ash, NaOH and a little NaCN. Small parts are handled in tumbling barrels. W. H. BOYNTON

Porosity of electrodeposited chromium. E. M. BAKER AND A. M. RENTZ. *Trans. Am. Electrochem. Soc.* 54 (preprint), 9 pp. (1928).—A study was made of the porosity of Cr deposited from CrO₃ plating baths. Findings of other workers have been confirmed and extended. Within the thicknesses of nil to 4×10^{-3} mm., a point of min. porosity was found to exist for all bath compns. and temps. investigated. The thickness of deposit necessary to give min. porosity increases with increasing bath temp., but the least porous deposits can be obtained at higher temps., about 55°. The nature and cause of porosity of electrodeposited Cr are discussed in some detail. C. G. F.

Present status of chromium plating technic. A. SIRMENS. *Z. Elektrochem.* 34, 264-9 (1928).—A review of the earlier work on Cr plating, followed by a discussion of the methods in use at present. H. STOERTZ

Steel anodes for chromium plating. E. M. BAKER AND E. E. PETTIBONE. *Trans. Am. Electrochem. Soc.* 54 (preprint), 3 pp. (1928).—Steel anodes are frequently used in Cr plating baths. The effects of variation in the % of C in the steel on the rate of anode corrosion, and on the oxidation of trivalent to hexavalent Cr, were studied. The steel having the lowest C was most resistant to corrosion; and electrolytic Fe was more resistant than steel. The equil. concn. of trivalent Cr was about the same for all of these anodes. C. G. F.

The co-deposition of copper and graphite. COLIN G. FINK AND JAMES D. PRINCE. *Trans. Am. Electrochem. Soc.* 54 (preprint), 6 pp. (1928).—Cu and graphite were co-deposited from CuSO_4 solns. Upon electrolyzing "aquadag," the graphite was deposited on the anode. Upon addn. of aquadag to acid CuSO_4 solns., graphite was deposited, with the Cu, on the cathode. Gelatin was used for stabilization, a little over 1 g./l. being sufficient. Upon analysis, as much as 16% graphite (42% by vol.) was found in the cathode deposit, the balance being Cu. C. G. F.

Current capacities of copper bars. ANON. (Electrolytic Equipment) Commonwealth Pr. Corp. of Mich. *Elec. World* 92, 407-8 (1928).—Data are presented for the detn. of the most economical max. current-carrying capacities of $\frac{1}{4}$ in. bus Cu bars. The values are given for a 30° rise in temp. with an ambient temp. of 25° . Various bus mountings are taken into account. C. G. F.

Process for maintaining or restoring the activity of negative plates in lead storage batteries. LÉON GAGNAUX. *Bull. soc. ind. Mulhouse* 94, 192-4 (1928).—(Sealed Note 1910, June 30, 1909).—Treatment of org. substances such as resins, starches, oils, fats, hydrocarbons, etc., with hot concd. H_2SO_4 yields products which, when added to the electrolyte in storage batteries (about 2-4 g. per l.), maintains, increases or restores the activity of the neg. plates. The method of treatment may vary with the nature of the substance, e. g., PhOH need only be heated to about 75° to form $\text{C}_6\text{H}_4\text{OHSO}_3\text{H}$ which is much more efficient for the purpose than PhOH, while resins must be heated above 100° . The activity can be repeatedly restored by repeated addns. The latter have no harmful effect on the pos. plates, but on the contrary retard their disintegration. The unsulfonated material can be incorporated into the plates in the course of manuf., either alone or in conjunction with the inert fillers generally used, and they are then sulfonated during the charging of the battery. Neg. plates prepd. by the Planté process can be treated either by reducing in an electrolyte contg. a certain amt. of the sulfonated products, or by immersing after reduction in a concd. soln. of the unsulfonated product, drying, and then immersing in H_2SO_4 at a high enough temp. to carbonylize and sulfonate the substance. Report. EDMOND BANDERET. *Ibid* 194-5.—The neg. plate of a small storage battery was treated with $\text{C}_6\text{H}_4\text{OHSO}_3\text{H}$. At the end of a few months, after repeated charging, the capacity had not varied. A. P.-C.

Maintenance of the volt (Weston cell). G. W. VINAL. *Trans. Am. Electrochem. Soc.* 54 (preprint), 9 pp. (1928).—The history of the international volt since it was defined by the Elec. Congress of Chicago, in 1893, is briefly reviewed. The present standard for the volt in the U. S. is a group of Weston normal cells, maintained by the Bur. of Standards at Washington. Seventeen years have elapsed since the value 1.01830 volts at 20° was established for the Weston normal cell, and it is a matter of importance, therefore, to det. how well the working standards have maintained this value. Results of recent measurements, which are the beginning of an extended investigation, indicate that the standard in this country has not changed by more than 1 or 2 parts in 100,000. Such data as are available on the value of the volt in several countries indicate differences that emphasize the importance of renewed work on this subject. Some suggestions for the proper care of the unsatd. form of standard cell which is used commercially are given. C. G. F.

A thermionic voltmeter for measuring the peak value and the mean value of an alternating (current) voltage of any wave form. E. B. MOULLIN. *J. (Brit.) Inst. Elec. Eng.* 66, 886-94 (1928).—Approx. analysis shows that the mean grid current is sensibly proportional to the peak value of any wave form, and results are tabulated of direct tests on 5 different wave forms the oscillograms of which are reproduced. C. G. F.

Corrosion in the tin can. I. The electrochemical relations of iron and tin. ROGER H. LUECK AND HAROLD T. BLAIR. *Trans. Am. Electrochem. Soc.* 54 (preprint), 22 pp. (1928).—In acid solns. free from appreciable concns. of oxidizing substance the usual electrochem. relations of Fe and Sn are reversed, Sn assuming an anodic relation to Fe. The polarity reversal in the Fe-Sn cell is due to the large value for the H overvoltage of Sn as compared with that of Fe. No reversal occurs if the accumulation of H on the initially cathodic Sn surface is prevented. A hypothesis is suggested to explain the perforating character of certain red fruits, as opposed to many uncolored fruits of equal H-ion concn. which do not perforate. C. G. F.

The use of misch metal as an electrolytic rectifier. H. C. KREMERS AND D. C. THOMAS. *Trans. Am. Electrochem. Soc.* 54 (preprint), 7 pp. (1928).—Many of the rare earth metals, including misch metal, form satisfactory films for electrodes in electrolytic rectifiers. The presence of Fe is detrimental. Electrolytes composed of aq. solns. of mono-, di- and tri-sodium phosphates, Na tungstate and a mixt. of NaOH and tri-

sodium phosphate were used. The latter soln. was found best for practical purposes. The mono-sodium phosphate soln., being slightly acid, caused too rapid corrosion of the misch metal electrode, and hence was proven unsatisfactory. The Na tungstate soln. indicated a slight tendency to corrode the misch metal. The disodium phosphate, although better than the Na tungstate, was not wholly satisfactory. The tri-sodium phosphate gave very good results; after continued operation for 2 weeks, the misch metal showed practically no corrosion. The electrolyte composed of 25% Na_2PO_4 and 10% of NaOH gave results equal to that of the 30% Na_3PO_4 , with the advantage of a considerable increase of cond. of the soln. From the series of tests it was concluded that misch metal, when prep'd, Fe free, is a satisfactory metal for electrolytic rectifiers. The formation of the film is very rapid, and once formed is permanent. With electrodes fabricated in sufficiently generous proportions, this metal should be entirely satisfactory for com. use. Alloys of misch metal with Al and Mg seem to promise satisfactory results. Exptl. work along these lines is being continued C. G. F.

The color temperature and luminous efficiency relation for tungsten. H. BUCKLEY, L. J. COLLIER AND F. J. C. BROOKES. *Rec. trav. comm. intern. éclairage* 6th Session, Geneva, 1924, Reprinted in *Natl. Phys. Lab. Collected Researches* 20, 387-401 (1927). E. J. C.

From Cu ore to heavy current cable (REDZICH) 9. An electrically heated furnace for organic combustions (PHILLIPS, HELLBACH) 1. Nickel mirrors by the nickel carbonyl method (FINK, KING) 19. Increasing the conductivity of metals (U. S. pat. 1,683,209) 9.

CRENNELL, F. M., AND LEA, F. M. **Alkaline Accumulators.** New York: Longmans, Green & Co. 140 pp. Price, about \$4.

Electric batteries. ALBERT FAUCHER. Fr. 634,688, May 19, 1927. Pb electrodes are placed in porous cells filled with an amalgam of granulated Pb and active material which consists of fragments of old battery plates, minium, litharge and MgSO_4 , the proportions differing for the positive and negative elements.

Dry-cell electric battery. EDWARD C. SMITH (to National Carbon Co.) U. S. 1,682,995, Sept. 4. Structural features.

Two-fluid electric battery with hollow carbon electrode. R. SCHUSTER. Brit. 283,142, Jan. 5, 1927. Structural features are specified of batteries which may have an electrolyte of K_2SO_4 or Na_2SO_4 , with or without K or Na silicate to form a jelly, and C and Zn electrodes.

Storage batteries. ACCUMULATEUR FARAD. Fr. 634,889, May 23, 1927. A new method of assembling the plates is described. Fr. 634,890 describes a battery made up of a no. of small elements contained in glass tubes, and a method of mounting these elements.

Wood separators for electric batteries. W. L. KANN. Brit. 283,221, Jan. 7, 1927. Virola wood or other similar suitable wood may be used for making separators without pretreatment.

Electric conductor. JAMES V. CAPICOTTO (to Dubilier Condenser Corp.). U. S. 1,683,064, Sept. 4. A material suitable for filaments of thermionic tubes comprises finely divided and intermingled Pt and Ir together with Ba and Sr which are evenly distributed through the mass of the conductor.

Electric condensers. R. BOSCH A-G. Brit. 283,144, Jan. 5, 1927. Material of condensers is impregnated with S and before solidification the materials are immersed in an insulating substance of low m. p. such as molten montan wax. This treatment prevents formation of air cavities as the S solidifies.

Electric rectifiers of the metallic oxide type. SIEMENS-SCHUCKERTWERKE A-G. Brit. 282,815, Dec. 31, 1926. In forming rectifiers such as those with Cu and Cu oxide elements, the oxide coating is formed on the metal by heating the latter in an O-contg. atm. in which the partial O pressure is reduced as compared with air at normal pressure, to an amt. which does not exceed the dissoen. pressure of the oxide at the reaction temp. This enables the desired oxide coating to be formed at temps. considerably below the m. p. of the metal and avoids formation of undesired products of oxidation.

Electrolytic rectifier. HARRY C. KREMERS. U. S. 1,682,846, Sept. 4. Filming electrodes of rare earth metals such as Ce, La and Nd are used with non-filming electrodes such as Pb or C and an electrolyte such as NaOH.

Electric resistance devices. VLADIMIR K. ZWORYKIN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,682,457, Aug. 28. Resistance devices suitable for use with thermionic tubes are prepd. by coating glass or other suitable carrier (to which a negative potential is applied) with material such as metal which is deposited from a vaporized state. An app. is described.

Electric resistance materials. R. C. BENNER and E. S. CAPRON (to Carborundum Co.). Brit. 283,076, April 5, 1927. A resistance such as a grid leak is molded from a plastic mixt. of a cond. material such as SiC and a non-cond. material such as clay, calcined and soaked in a waterproofing material of high dielec. const. such as paraffin or ceresin.

Electrodeposition of metals on aluminum and its alloys. H. WEBB and S. O'BRIEN & PARTNERS, LTD. Brit. 283,288, Oct. 9, 1926. Al or an Al alloy is treated with strong HNO_3 before being electroplated with Ni, Zn, Cu or other metals, with or without treatment with alkali to remove grease, etc., and after the plating operation is heated considerably above 100° . When a metal salt other than a nitrate is used in the plating bath, the metal to be plated is dipped in a soln. of the acid corresponding to the salt used after being treated with HNO_3 . Cu may be deposited and Au, Ag, Sn, Pb or Cd then deposited on the Cu from a cyanide bath. Various details and modifications are given.

Cadmium plating. LEON R. WESTBROOK (to Grasselli Chemical Co.). U. S. 1,681,509, Aug. 21. A compn for use in forming an electrolyte for Cd plating comprises Cd hydroxide 50, a compd. of Ni such as Ni sulfate which is sol. in an aq. alkali metal cyanide soln. about 0.18, Na_2SO_4 38 and guiac about 11.5 parts. Cf. C. A. 22, 1906.

Nickel-plating. L. F. NELISSEN. Brit. 282,748, Dec. 30, 1926. Articles to be Ni-plated are cleaned and given a preliminary thick coating of Cu, and then polished by brushing before deposition of the Ni.

Electrolysis, particularly for the manufacture of caustic soda. PAUL LÉON HULIN. Fr. 634,952, Sept. 22, 1926. Metal electrodes particularly those used in the manuf. of NaOH are de-amalgamated by combining with the usual electrode, a non-amalgamated supplementary electrode, which forms, when desired, another galvanic couple with the first and so produces de-amalgamation thereof.

Electrolytic treatment of materials containing copper and nickel. CHEMISCHE FABRIK JOHANNSTHAL GES. AND F. TROSTLER. Brit. 283,132, Jan. 4, 1927. Cu- and Ni-bearing materials such as alloys, mat or speiss are treated as anode in a neutral or weakly basic electrolyte such as NaCl soln. Cu and Ni hydroxides are pptd. as mud which is then treated with a soln. of a Cu salt such as the chloride or sulfate (preferably in excess, and repeatedly if required) until the Ni hydroxide goes into soln. Pb, when present, remains with the Cu together with As and S. Numerous details are given.

Apparatus for electrolytic production of sheets and similar articles from metals or other materials. JOHANN C. F. A. SCHUTTE. U. S. 1,682,426, Aug. 28. Ores may be used in the app.

Coating aluminum. EUGÈNE PAUL, MARIUS GAT and EUGÈNE MARIE LOUIS CARRIÈRE. Fr. 635,002, May 25, 1927. To cover Al or Al alloys with a protecting coat, the surfaces to be coated are first dipped in an electrolytic bath contg. sulfate of iron, in dil. H_2SO_4 for a very short time and then into an electrolytic bath of Ni, Cu, Cr, Co or the like.

Aluminum. SOCIETÀ ITALIANA DI ELETTROCHIMICA. Fr. 634,727, May 20, 1927. For the production of Al in elec. furnaces, hydrated AlCl_3 , or $\text{Al}(\text{OH})_3$ prepd. by partly or completely decomp. hydrated AlCl_3 , or $\text{Al}(\text{OH})_3$ to which hydrated AcCl_3 has been added, is used.

Aluminum. SOCIETÀ ITALIANA DI ELETTROCHIMICA. Fr. 634,728, May 20, 1927. To prevent $\text{Al}(\text{OH})_3$ rising as dust when used in elec. furnaces for the production of Al, it is agglomerated in small grains or larger pieces by substances such as gelatin, gum or colloids or is submitted to pressure at a convenient temp.

Electric furnace for annealing metal articles. EISEN- UND STAHLWERK HOESCH A.-G. AND W. HEIDENHAIN. Brit. 282,750, Dec. 28, 1926. Articles of iron, steel or other ferro-magnetic materials are held in tubes of an elec. furnace heated by a coil, by a magnetic field (produced by another coil) until magnetic change occurs when they slide down the tube (which is inclined) and drop into a tempering bath after having been heated to the hardening temp.

Electric induction furnace. G. E. TAYLOR and ELECTRIC FURNACE CO., LTD. Brit. 283,302, Oct. 25, 1926.

Electric induction furnace adapted for melting metals. ROLLO B. LINCOLN (to Westinghouse Elec. & Mfg. Co.). U. S. 1,682,388, Aug. 28. Structural features.

Water-cooled electric induction furnace. EDWIN F. NORTHRUP (to Ajax Electro-Thermic Corp.). U. S. 1,681,950, Aug. 28. Structural features.

Electrode mounting for electric furnaces. SOC. ELECTRO-METALLURGIQUE DE MONTRICHTER. Brit. 282,747, Dec. 28, 1926.

Carbon electrodes. VICTOR C. DOERSCHUK (to Aluminum Co. of America). U. S. 1,683,587, Sept. 4. A normally unconsolidated mixt. of granular material such as crushed C material and viscous bituminous binder is placed in a mold and the mold is jarred to effect molding into a coherent mass.

Electrodes for arc lamps. IAN J. LAVOISIER (to Burdick Corp.). U. S. 1,682,847, Sept. 4. A dehydrated and glazed mixt. of Zr and Yt oxide is used for electrodes of *therapeutic lamps*. Various modifying substances may be added.

Filling tubular electrodes. COMPAGNIE GÉNÉRALE D'ÉLECTRICITÉ. Fr. 634,882, May 23, 1927. The active material is projected into tubular electrodes, particularly for Edison accumulators, as a thick paste and compressed by centrifugal force.

High-frequency electric induction heating apparatus suitable for heating materials in crucibles. ELIHU THOMSON (to General Electric Co.). U. S. 1,683,146, Sept. 4.

Electrically heated oil bath vacuum oven. PAUL E. KLOPSTEG (to Central Scientific Co.). U. S. 1,683,359, Sept. 4.

Electric wave collector. HALL ÉLECTRIQUE MODERNE. Fr. 634,690, May 19, 1927. A wave collector mounted in a vacuum tube of SiO_2 is made of a spiral Cu wire covered with a thin layer of pure gold, and the extremities of the spiral embedded in the tube are of Mo.

Treating gases with high-tension electric arcs. EMIL EDWIN (to Aktieselskapet Norsk Staal Elektrisk-Gas-Reduktion). U. S. 1,683,534, Sept. 4. See Norw. 43,570 (C. A. 21, 2106).

Lamp filaments. SOCIÉTÉ DES ÉTABLISSEMENT INDUSTRIELS DE E.-C. ET DE ALEXANDRE GRAMMONT. Fr. 634,828, May 21, 1927. A lamp filament is attached to a Mo support by a strip of metal such as Ni soldered to the Mo, and squeezed on to the filament.

5—PHOTOGRAPHY

C. E. K. MEES

Investigations of the sensitizing action of some panchromatic sensitizing agents. EMILIO VITERBI. Univ Padova. *II Progresso Fotografico* 1927, No. 1-2, 9 pp.; *Chem. Zentr.* 1927, II, 202-3; cf. C. A. 21, 710, 2852.—Following the methods reported previously, plates of medium sensitivity (Cappelli green label) were treated with aq. alc. solns. of the following sensitizing dyes in order to study their action: Orthochrome T, Pinaverdol, Pinachrome, Pinacyanol, Pinachrome Violet, Pinachrome Blue, Ethyl Cyanine, Isoquinoline Red, Pinaverdol and Dicyanine A. C. C. DAVIS

Photographic action of H-rays from paraffin and atom fragments (BLAU) 3.

• **Color photography.** ERNST A. LAGE. U. S. 1,683,560, Sept. 4. See Brit. 266,468 (C. A. 22, 548).

Photographic emulsions. I. G. FARBENIND. A.-G. Brit. 283,222, Jan. 7, 1927. Sensitivity of Ag salt emulsions is increased by using as a carrier for the Ag salt (either alone or mixed with gelatin) the product obtained by treating gelatin or similar material with S or S compds. such as an alk. earth sulfide or CS_2 . A very small proportion of Na_2S may be used with gelatin soln. and any excess of sulfide may be rendered harmless by careful oxidation, e. g., with HClO_4 . Brit. 283,223 specifies increase of sensitivity by addn. of substances such as K dithiocyanate, disulfide of HOAc, disulfide of β -mercaptothiocinnamic acid or compds. of similar character.

Photographic films. H. J. HANDS and SPICERS, LTD. Brit. 282,980, Dec. 29, 1926. Supporting films are formed of mixts. such as those of cellulose and cellulose acetate (or other suitable carbohydrate and carbohydrate esters or ethers) together with solvents, plasticizing agents, etc.

Photographic diazotype processes. E. GAY. Brit. 282,894, Sept. 30, 1926. In processes involving the formation of azo dyes by reaction of diazo compds. sensitive to light upon phenols, naphthols or amines in the presence of an alkali such as Na_2CO_3 ,

diazo compds. are used which are derived from anisidines or naphthanisidines and alkyl ethers or *o*-aminophenol or *o*-aminonaphthols or their nuclear substitution products. Several examples are given.

Photographic diazotype processes. E. GAY. Brit. 283,274, Oct. 6, 1926. The process of Brit. 282,894 (preceding abstr.) is modified by including in the sensitive layer phenol or naphthol derivs. which form with the diazo compd. a stable mixt. and which regenerate phenols or naphthols when treated with alkalis, so that a developer contg. alkali only may be used. Acetyl derivs. of phenols, naphthols, dihydroxynaphthalenes or aminonaphthols, and phenolic esters derived from formic acid, oxalic acid or benzenesulfonic acid may be used. Several examples are given.

Chromophotographic apparatus. COMPAGNIE INTERNATIONALE TRICROMIA. Fr. 634,860, May 23, 1927. Means for accurately adjusting the reflecting shields of Fr. 560,438 are described.

Coating composition. WM. H. GARDNER. U. S. 1,682,957, Sept. 4. A compn. suitable for coating developed photographic plates is formed from spar varnish 1 pint, ether 4 oz., japan drier 1 oz., Venice turpentine 1 oz. and collodion 2 oz.

6—INORGANIC CHEMISTRY

A. R. MIDDLETON

Reduction of nitrites, nitrates and nitric acid with magnesium amalgam: a new method of preparing hyponitrites. PANCHANAN NEOGI AND BIRENDRA LAL NANDI. President College, Calcutta. *J. Chem. Soc.* 1928, 1449-55.—The action of Mg amalgam (I) on metallic nitrites and nitrates is studied, a convenient method of prepg. hyponitrite(s) (II) being afforded. Its advantages, over the Na I method of prepg. the known II, are that it is more direct, and that $Mg(OH)_2$ is more readily removed than NaOH, does not enter into secondary reactions and does not tend to decomp. unstable II. The magnesium amalgam used is prepd. by heating for 2-3 min., Mg (20 g.) and Hg (400 g.), shaking every 10 min. until the Mg is completely dissolved, cooling and cutting into small pieces. In prepg. II all solns. must be kept below 5° in an ice-salt mixt. In all cases the method of reduction used is similar to that employed in prepg. the Li salt. This process is repeated until the soln. contains no nitrite, before concg. In prepg. the Li, Na, K, Ca, Ba and Sr II, the solns. resulting from the reduction contain NH_4OH , hydroxylamine (III), and the resp. II and hydroxide (IV), but no Mg salt; with Rb and Cs II they contain NH_4OH , and the resp. II and IV, but no III; and with Zn, Cd and Pb II they contain NH_4OH and III, but none of the resp. II, this going entirely into the ppt. **Lithium hyponitrite** ($Li_2N_2O_2$) is prepd. by adding Mg I to a concd. $LiNO_3$ soln., keeping for a short time, filtering off the pptd. $Mg(OH)_2$ and washing with ice water. This reduction is repeated until no nitrites and nitrates are present in soln., after which the final soln. is placed in a vacuum desiccator over concd. H_2SO_4 (call this operation, V) for 2 weeks in which time III is decompd. (the resulting NH_3 being absorbed by the acid), and a white, solid mass of LiOH and $Li_2N_2O_2$ remains. By repeatedly extg. with abs. alc. and pptg. with Et_2O , $Li_2N_2O_2$ is obtained free of LiOH, which is dissolved in a min. of H_2O , evapd. to dryness in V and analyzed, the slightly high results being due to hydrolysis during the final crystn. **Sodium hyponitrite** and **potassium hyponitrite** are prepd. by reducing $NaNO_3$ (35 g. in 200 cc. H_2O) and KNO_3 (40 g. in 250 cc. H_2O), resp., with 5% Mg I (420-450 g.), evapg. for 20 days in V, extg. the IV with abs. alc., leaving Na and K II which are dried in a vacuum desiccator. **Rubidium hyponitrite** ($Rb_2N_2O_2 \cdot 2H_2O$) and **cesium hyponitrite** ($Cs_2N_2O_2 \cdot 8H_2O$) are prepd. by reducing their nitrates, keeping overnight in V, neutralizing with dil. AcOH, concg. in V and washing with abs. alc. until the crystals are free of acetate. **Magnesium hyponitrite** is prepd., but not isolated, by reducing $Mg(NO_3)_2$ (40 g.) in H_2O (250 cc.), the Mg II being totally pptd. When this is dissolved in 6% AcOH, the filtered soln. gives a test for II, but keeping overnight in a vacuum desiccator decomposes the Mg II therein. Alkalies also decompose it and attempts to isolate it in org. media proved unsuccessful. **Zinc hyponitrite** ($Zn_2N_2O_2 \cdot H_2O$) is prepd. by reducing $Zn(NO_3)_2$ (20 g. in 200 cc. H_2O) contg. a few drops of HNO_3 , filtering off the ppt., washing, dissolving (with cooling) in a min. of AcOH (6%), neutralizing with NH_3 , and after keeping for 2-3 hrs. filtering the gelatinous ppt., sepg., washing, dissolving in AcOH and repptg. by neutralization, repeating this 5 times to remove completely the $Mg(OH)_2$ and $Zn(OH)_2$, the ppt. finally obtained being Zn II. **Cadmium hyponitrite** ($Cd_2N_2O_2$) is prepd. by reducing $Cd(NO_3)_2$, treating the ppt. similarly to the Zn, redissolving in HNO_3 and neutralizing 6 times, being finally

obtained as a yellow powder. *Cadmium hydroxyhyponitrite* ($\text{Cd}(\text{OH})(\text{NO})$) is obtained during the soln. and reprecip. of the preceding. *Calcium hyponitrite* ($\text{CaN}_2\text{O}_4 \cdot 4\text{H}_2\text{O}$), *strontium hyponitrite* ($\text{SrN}_2\text{O}_4 \cdot 5\text{H}_2\text{O}$) and *barium hyponitrite* ($\text{BaN}_2\text{O}_4 \cdot 4\text{H}_2\text{O}$) are prepd. by reducing their nitrates, the **II** present in small quantity in the ppt. extd. with cold H_2O and combined with the soln., which is then kept in **V** for a day to remove NH_3 and **III**, neutralized with H_3PO_4 (to remove the resp., **IV**), filtered, concd in **V**, the cryst. mass washed with abs alc and dried. *Lead hyponitrite* (PbN_2O_4) is prepd. by reducing $\text{Pb}(\text{NO}_3)_2$ (20 g in 200 cc. H_2O), the ppt dissolved in cold dil. AcOH and neutralized, this dissoln. and neutralization being repeated, and the resulting ppt. filtered off, washed and dried. *Lead oxyhyponitrite* ($\text{PbO PbN}_2\text{O}_4$) is obtained when the final ppt of the preceding is treated with AcOH and NH_3 4-5 times at room temp., the resulting ppt. being filtered off, washed and dried. $\text{Hg}(\text{NO}_3)_2$, $\text{Hg}_2(\text{NO}_3)_2$, $\text{Co}(\text{NO}_3)_2$, $\text{Cu}(\text{NO}_3)_2$, $\text{Ni}(\text{NO}_3)_2$, AgNO_3 and NH_4NO_3 were also reduced, but in no case was a **II** obtained. *Hydroxylamine sulfate* is prepd. by reducing HNO_3 (200 cc of 10%) and H_2SO_4 (20 cc. of 10%), filtered, the filtrate reduced with H_2SO_4 (5 cc of 10%), repeating 5 times, the resulting soln. evapd. on water bath, and **III** sulfate removed from MgSO_4 and $(\text{NH}_4)_2\text{SO}_4$ by repeated extn with warm abs alc. The yield of **III** sulfate is 60% of the HNO_3 used, its purity being estd. as 97.8% by Raschig's method. Analyses of the compds. checked with the theoretical. J BALOZIAN

The reduction of barium carbonate by aluminum. ERWIN F. LINHORST AND HERMAN SCHLUNDT. *Trans. Am. Electrochem. Soc.* **54** (preprint), 8 pp (1928). -The reaction was found to be vigorous, and the immediate product was found to be complex. Pptd. Ba carbonate and powd. Al, the particles of which were all less than 4 microns in diam., were well mixed in a molar ratio of 1 to 2. An iron sand bath contg. 1000 g. of this mixt. was heated over a large burner, until the temp. at the hottest portion reached 400° . The reaction then started at the hottest point and traveled to all parts of the mass, even though most of the material had not been heated much above 200° , as detd. by a mercurial thermometer projected into the body of the material at various points. The reaction is highly exothermic. The temp. rises above 1400° in the interior of the reaction mixt., high enough to fuse the product into a dense mass. During the reaction, gases are given off in considerable amt. They take fire and burn with a bluish flame at first, but later the flame becomes luminous and intensely bright. The reaction product obtained is a heavy gray mass, d 3.5 and hardness about 5.5, as it scratches glass but not orthoclase: $\text{BaCO}_3 + 2\text{Al} \rightarrow 0.12\text{C} + 0.41\text{CO} + 0.428\text{Al} + 0.104\text{BaC}_2 + 0.087\text{Al}_2\text{C}_3 + 0.328\text{Ba}(\text{AlO}_2)_2 + 0.284\text{Ba}_2\text{Al}_2\text{O}_5$. C G. F.

Hydrated tricalcium aluminate. A TRAVERS AND SEHNOUTKA. *Compt. rend.* **187**, 381-2 (1928). -When T. and S. repeated the expts of Allen (*Am. Chem. J.* **24**, 304 (1900)) in an attempt to prep. the hydrated dicalcium aluminate mentioned by him, they were able to obtain only cryst. lime. Believing that the method used by Lafuma (*Thesis*, Paris, 1925), namely that of starting with anhyd. aluminates, gave inaccurate results, they used very dil. solns. for the prepn. of the compd. sought. To 1 l. of $M/30 \text{ KAlO}_2 \cdot 3\text{H}_2\text{O}$ was added 1.1 l. of a mixt. composed of 1 l. of $M/47 \text{ Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ and 100-150 cc. of satd. limewater. After several hrs. pure $\text{Al}_2\text{O}_3 \cdot 3\text{CaO} \cdot 21\text{H}_2\text{O}$ (**I**) crystd. If only 50 cc. of limewater were used a mixt. of $\text{Al}(\text{OH})_3$ and tricalcium aluminate was pptd.; if 200 cc., there appeared in addn. to **I** other cryst. forms not yet studied. The ρ_{H} at which **I** was formed was between 11.55 and 11.62. LOUISE KELLEY

The preparation of pure platinum. E. H. REERINK. Lab. of Phillips Lamp Works, Eindhoven. *Z. anorg. allgem. Chem.* **173**, 45-8 (1928). -A simple method for the prepn. of pure Pt consists in heating a thin Pt wire in the vapor of a volatile Pt compd. to a temp. at which the compd. decomposes, depositing a compact layer of Pt on the wire. Other metals may be used for the wire. A layer of Pt may be deposited upon metals, e. g., W, Mo, Ni, where, by electrolytic methods it is difficult if not impossible. The coatings thus formed are thick and adhere well and wire thus covered has almost all of the properties of a Pt wire. The volatile Pt halogen carbonyl compds. are used. Asbestos wool is impregnated with concd. PtCl_4 and then placed in a vertical glass tube set over a porcelain filter plate. Dry CO_2 is passed through slowly for 2 hrs. After most of the PtCl_4 is changed to PtCl_2 , CO_2 is replaced by CO at 250° . The product is evidently a mixt. of compds. of which the following have been described: $\text{Pt}(\text{CO})_2\text{Cl}_2$, $(\text{PtCl}_2)_2(\text{CO})_2$, PtCoCl_2 and $\text{PtCl}_2(\text{COCl})_2$. Analysis of the product gave Cl 23%; Pt 61.4%. This material collects in the lower part of the app. where, at the completion of the reaction, it is fused into a compact mass in which form it is more resistant to moisture. The optimum temp. for decompn. of these volatile compds. is 600° . The gaseous products contain CO , Cl_2 and COCl_2 . The best deposits are obtained at 0.02-0.01 mm. pressure. Attempts to form analogous halogen-carbonyl

comps. with Rh, Pd or Ir under similar conditions were unsuccessful. The Pt compd. can thus be prepd. free from the other metals.

The stability of rhodium sesquioxide and iridium dioxide. S. PASTORELLO. Univ. Milano. *Atti. accad. Lincei* [6], 7, 754-7(1928).—The suggestion of Levi and Faldini (C. A. 21, 3106) that the poisonous action of Rh and Ir on the catalytic action of Pt in the oxidation of SO_2 is a result of oxide formation induced P. to investigate the stability of Rh_2O_3 and of IrO_2 in SO_2 . X-ray examn. of Rh_2O_3 in SO_2 at 350°, 450° and 500° showed a splendid photograph of pure metallic Rh at 500°, which conforms to the rapid change of direction of the curve of Levi and Faldini (*loc. cit.*) above 450°. The small temp. interval of the transformation is noteworthy. With IrO_2 in SO_2 at 350°, 450°, 550°, 650°, 750°, 850° and 900°, x-ray examn. showed only pure IrO_2 from 350° to 650°, a mixt. of IrO_2 and metallic Ir at 750° and only pure Ir at 900°. No intermediate oxides were detected. From the intensities of the lines at 750°, it was calcd. that at this temp. the mixt. of IrO_2 and Ir contained 68.80% Ir. The results indicate that the deleterious action of Ir and Rh in the oxidation of SO_2 with Pt catalyst results from the formation of their oxides.

Selenium tetrafluoride. EDMUND B. R. PRIDEAUX AND CHARLES B. COX. Univ. College, Nottingham. *J. Chem. Soc.* 1928, 1603 7.—Selenium tetrafluoride (colorless, fuming liquid) is prepd. by mixing 4-5 parts of AgF (prepd. by Ruff's method, cf. Prideaux and Cox, C. A. 22, 1924) and 1 of Se in a Pt vessel set in a Monel metal pot, heating to 50-60° to start the reaction, distg. and redistg. from AgF completely to remove SeCl_4 . The yields are reduced by the presence of SeOF_4 , most probably due to Ag_2O in the AgF used. On prepg. again, 9.14 g. of SeCl_4 gave 5.12 g. of distillate, which on redistn. below 140° yielded 4.42 g. SeF_4 , analysis by different methods showing 51.0-52.1% Se and 47.2-47.7% F_2 . The d. of SeF_4 , as detd. in the Monel bottle (C. A. 22, 1924), is 2.77; the b. p., detd. in the same, is 93°. The m. p. is detd. by inserting the bulb of Pt-foil-covered pentane thermometer into the liquid contained in a small Pt vessel, which in turn is set in a glass tube. The liquid is quickly frozen and allowed to warm slowly, a graph of the temp.-time readings detg. the m. p. as -13.2° . SeF_4 attacks Si in the cold, giving SiF_4 , this being proportional to the combined F; it also reacts with red P giving PF_3 and POF_3 , with a residue of red Se and SeO_2 , this action being proportional to the Se in combination and soln., but inhibited by an excess of HF .

Precipitated zinc sulfide. G. R. LEVI AND C. G. FONTANA. Univ. Milano. *Atti. accad. Lincei* [6], 7, 502-8(1928).—A survey of the rather extensive literature on the pptn. of ZnS (references to which are given) shows a disagreement in results. ZnS was therefore pptd. under different conditions and was examd. to det. (1) its cryst. form under varying conditions, and (2) whether the cryst. granules had different dimensions. The ZnS was pptd. by H_2S from N ZnSO_4 (1) made alk. with NaOH , (2) made alk. with NH_4OH , (3) made acid with AcOH and (4) with no other reagent, after which it was let stand 24 hrs., filtered, washed, dried *in vacuo* and examd. by the powder method with x-rays. The data, recorded in complete form, show dimensions of the 4 preps. of 19.74, 18.60, 22.00 and 20.60 Å. U., resp., which is considered evidence that all 4 preps. were of identical size. Therefore the different behavior during analysis of ZnS under different conditions must depend upon the varying state of agglomeration and not upon the dimensions of the granules. The cryst. form was in all cases the same as that of Zn blende.

Salt-like hydrides. III. M. PROSKURNIN AND I. KAZARNOVSKII. *Z. anorg. allgem. Chem.* 170, 301-10(1928).—App. is described in which the d. of the hydrides can be detd. pycnometrically with the exclusion of air. The d. of the hydrides of Na, K, Rb and Cs is detd. and given as follows: for NaH 1.38 ± 0.04 , KH 1.47, RbH 2.60 ± 0.07 , CsH 3.42 ± 0.1 . Moissan's values are much too low. In taking up H , a large contraction of the metal lattice takes place, which is greater for the alkali hydrides than for the alk. earth hydrides. Thus with LiH the vol. contraction in % is 24.6, with NaH 26.6%, KH 40.0%, RbH 40.7%, CsH 44.9%, CaH_2 4.2%, BaH_2 13.3%. Comparison of the mol. vol. of the hydrides with the halogenides shows a great similarity between the hydrides and fluorides. Mol. vol. of LiH is 9.8, LiF 9.98, LiCl 20.53; while for CaH_2 mol. vol. is 24.8, CaF_2 24.6, CaCl_2 50.0. The ion radius of the H ions is 1.45 Å. U.

The system copper sulfate-ammonium oxalate-ammonia. M. HERSCHKOWITZ. Carl Zeiss Works, Jena. *Z. anorg. allgem. Chem.* 173, 222-4(1928).—A bath of Cu NH_4 oxalate gives a lustrous thick deposit with good scattering power. Within a short time a deposit forms leaving the bath poorer in Cu and then the anodes become covered with this deposit. Different crystals are found, difficult to sep. and which

gave varying analytical results. While the molar proportion of Cu to oxalic acid was always 1:1, the ratio of NH_3 to H_2O of crystn. and to Cu was neither const. nor integral. The Cu oxalate ppt. was dissolved in NH_4 oxalate and this was added to a soln. of CuSO_4 . A clear soln. was obtained which was stable for several months. Upon adding NH_3 a cryst. ppt. was obtained, heterogeneous under the microscope. Tiny bluish green crystals were analyzed as $\text{Cu}(\text{CO}_3)_2\text{NH}_3$ derived from a soln. contg. 0.04 mol. CuSO_4 , 0.12–0.16 mol. NH_4 oxalate and 0.02–0.08 mol. NH_3 . From solns. with a large excess of NH_3 homogeneous hexagonal ultramarine-blue crystals were obtained which analyzed as $\text{Cu}(\text{CO}_3)_2 \cdot 2\text{NH}_3 \cdot 2\text{H}_2\text{O}$. These lose all their water below 50° , forming $\text{Cu}(\text{CO}_3)_2 \cdot 2\text{NH}_3$. The addn. of oxalic acid to solns. of CuSO_4 in NH_4 oxalate produces a turbidity and the ppt. is a blue green difficultly drying amorphous mass which contains no NH_3 and is Cu oxalate.

S. L. B. ETHERTON

The system $\text{KCl-HCl-H}_2\text{O}$ between 0° and 80° . G. MALQUORI. Univ. Roma. *Atti accad. Lincei* [6], 7, 738–9(1928).—Data on the same system at 0° (cf. Seidell, *C. A.* 14, 380) and at 25° (cf. M., *C. A.* 22, 529) have already been published. With these data and new data for 40° , 60° and 80° , a 3-dimensional diagram is given, in which the coordinates are the temp., the concn. of HCl (only 10 and 25% are shown) and the soly. of KCl. HCl lowers the soly. of KCl but does not alter the course of the curves as functions of the temp.

C. C. DAVIS

The system $\text{AlCl}_3\text{-HCl-H}_2\text{O}$ between 0° and 80° . G. MALQUORI. Univ. Roma. *Atti accad. Lincei* [6], 7, 740–4(1928).—Like the data on the system $\text{KCl-HCl-H}_2\text{O}$ (cf. preceding abstr.), the present data are of importance in the fractional crystn. of liquids from the attack of leucite with HCl by the Blanc process (*C. A.* 19, 1616; 20, 3335). To construct a polythermic diagram of the system $\text{AlCl}_3\text{-HCl-H}_2\text{O}$, the system $\text{AlCl}_3\text{-H}_2\text{O}$ was first studied by detg. the ice curve and the soly. curve from the cryohydrate temp. to 80° . The data, given in tabular and graphical form, show that in this latter temp. range only $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$ exists in equil. with the satd. soln. $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$ dissolved in 900 mol. of water at 15.5° evolves 26.4 cal. This is the integral heat of soln. of $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$, since it includes the heat of diln. By detg. the integral heat of soln. at 20° , using the same proportions of $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$ and water used by Sabatier (cf. *Bull. soc. chim.* [3], 1, 88(1889)), taking a vol. of soln. satd. at 20° contg. the same quantity of salt used above, dilg. with the same quantity of water, and detg. the difference of the 2 calorimetric values, it was found that the heat of soln. considered as the heat evolved in the soln. of 1 mol. of $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$ at 20° to give a satd. soln. is 4600 cal. The 3-dimensional diagram of the system $\text{AlCl}_3\text{-HCl-H}_2\text{O}$ at 0° , 25° , 40° , 60° and 80° shows that HCl lowers the soly. of AlCl_3 , but as with KCl it does not alter the course of the curves as functions of the temp.

C. C. DAVIS

The system $\text{AlCl}_3\text{-KCl-H}_2\text{O}$ between 0° and 80° . G. MALQUORI. Univ. Roma. *Atti accad. Lincei* [6], 7, 745–7(1928); cf. *C. A.* 22, 529 and preceding 2 abstrs.—The data are given in tables and as a 3-dimensional polythermal diagram for 0° , 40° , 60° and 80° . The soly. relations are completely normal, and only the proportion of KCl to AlCl_3 in the satd. soln. of the 2 salts varies somewhat with the temp., the KCl concn. becoming greater as the temp. increases.

C. C. DAVIS

The systems $\text{Pb}(\text{NO}_3)_2\text{-LiNO}_3\text{-H}_2\text{O}$ and $\text{Pb}(\text{NO}_3)_2\text{-CsNO}_3\text{-H}_2\text{O}$ at 25° . G. MALQUORI. Univ. Roma. *Atti accad. Lincei* [6], 7, 495–6(1928); cf. *C. A.* 22, 2308.—A comparison of the results obtained for the systems: $\text{Pb}(\text{NO}_3)_2\text{-LiNO}_3\text{-H}_2\text{O}$ and $\text{Pb}(\text{NO}_3)_2\text{-CsNO}_3\text{-H}_2\text{O}$ and those of $\text{Pb}(\text{NO}_3)_2\text{-KNO}_3\text{-H}_2\text{O}$ and $\text{Pb}(\text{NO}_3)_2\text{-NaNO}_3\text{-H}_2\text{O}$ (cf. Glasstone and Saunders, *C. A.* 17, 3844) at different temps., shows that hydration of the alk cations plays a part in the variations in the soly. which were observed, i. e., the increase in the soly. of $\text{Pb}(\text{NO}_3)_2$ caused by the addn. of alk. nitrate increases with the ionic radius of the cation. On the other hand, the fact that the lower the temp. the greater is the increase in soly. establishes the existence of complexes. The measurements are given as a triangular soly. diagram. Further expts. are in progress on the cond. and viscosity as functions of the temp. and concn.

C. C. DAVIS

The causes which determine the influences of solubility between lead nitrate and alkaline nitrates. G. MALQUORI. Univ. Roma. *Gazz. chim. ital.* 58, 203–8(1928).—To explain the increase in the soly. of $\text{Pb}(\text{NO}_3)_2$, brought about by NH_4NO_3 (cf. *Atti II congresso naz. chim. pura applicata* 1926, 1135) and to det. whether it is due to hydration or to complex formation, the systems $\text{LiNO}_3\text{-Pb}(\text{NO}_3)_2\text{-H}_2\text{O}$ and $\text{CsNO}_3\text{-Pb}(\text{NO}_3)_2\text{-H}_2\text{O}$ at 25° were studied. The method was that used before and the results are given in tables and triangular diagrams. Data on the systems $\text{NaNO}_3\text{-Pb}(\text{NO}_3)_2\text{-H}_2\text{O}$ and $\text{KNO}_3\text{-Pb}(\text{NO}_3)_2\text{-H}_2\text{O}$ by Glasstone and Saunders (cf. *C. A.* 17, 3844) are also plotted for comparison. The influence of the alk. nitrates on the soly. of $\text{Pb}(\text{NO}_3)_2$ increases in the order: $\text{Li} < \text{Na} < \text{K} < \text{Cs}$, which is the order in which the ionic radii

increase, according to Pauling (cf. *C. A.* 21, 1384). Hydration of the alk. ions, already known to be great, varies inversely with the ionic rays, so the more water held by each ion, the smaller the soly. of the $\text{Pb}(\text{NO}_3)_2$. Complex formation (cf. Lewis, *Diss.* Breslau, 1908) opposes the influence of hydration, as is evident from a comparison of the soly. of the system $\text{NH}_4\text{NO}_3\text{--Pb}(\text{NO}_3)_2\text{--H}_2\text{O}$ at 0° and 25° , the soly. of $\text{Pb}(\text{NO}_3)_2$ being greater at 0° because of complex formation. The tendency to form complexes increases from Li to Cs.

C. C. DAVIS

Hydrates of the nitrates of cadmium, zinc and magnesium. G. MALQUORI. Univ. Roma. *Gazz. chim. ital.* 58, 209–16(1928).—The systems $\text{Cd}(\text{NO}_3)_2\text{--HNO}_3\text{--H}_2\text{O}$, $\text{Mg}(\text{NO}_3)_2\text{--HNO}_3\text{--H}_2\text{O}$ and $\text{Zn}(\text{NO}_3)_2\text{--HNO}_3\text{--H}_2\text{O}$ at 20° were studied by the method used by M. so often before. The results, which are recorded in tables and a graph, showed the existence of the following *hydrated salts* in equil. with solns. contg. the % HNO_3 given: $\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$, 52.95%; $\text{Cd}(\text{NO}_3)_2 \cdot 2\text{H}_2\text{O}$, 60.01%; $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$, 34.45%; $\text{Zn}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$, 59.21%; $\text{Mg}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$, 49.12%. $\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ is completely dehydrated at 20° by HNO_3 of d. 1.52, while $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ loses only $2\text{H}_2\text{O}$ and $\text{Mg}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ is unaltered, which is in accord with their relative vapor pressures (cf. *Ann. chim. phys.* [7], 7, 416(1896)), with the ionic radii (the smaller the latter the firmer the union with water of hydration) and with their m. ps. (the firmer the union the higher the m. p.). The *heat of hydration* of $\text{Cd}(\text{NO}_3)_2$ was found to be 11.52 cal. On being heated, $\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ loses only H_2O , whereas $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ and $\text{Mg}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ lose H_2O and HNO_3 simultaneously with formation of *basic anhyd.* or *partly hydrated salts*, the products depending upon the conditions. Like the previous phenomena this may be explained by the theory of Lambert (cf. *C. A.* 17, 2241).

C. C. DAVIS

Double sulfates of rare earth metals and alkali metals. XI. Cerium (cerous) and rubidium sulfates. F. ZAMBONINI AND SILVIA RESTAINO. *Atti accad. Lincei* [6], 7, 449–52(1928); cf. Z. and Stocchi, *C. A.* 21, 3841.—The system $\text{Ce}_2(\text{SO}_4)_3\text{--Rb}_2\text{SO}_4\text{--H}_2\text{O}$ was studied by the same method already employed. At 25° only 1 compd. was formed, viz., the *double salt*, $\text{Ce}_2(\text{SO}_4)_3 \cdot \text{Rb}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$. It has a wide field of existence, since at 25° it is stable in contact with solns. contg. from 34% Rb_2SO_4 and no $\text{Ce}_2(\text{SO}_4)_3$ to solns. contg. 1.3% Rb_2SO_4 and 0.2% $\text{Ce}_2(\text{SO}_4)_3$. Subsequent expts. at other temps. gave 2 other *double salts*, viz., $\text{Ce}_2(\text{SO}_4)_3 \cdot \text{Rb}_2\text{SO}_4 \cdot 8\text{H}_2\text{O}$ and $\text{Ce}_2(\text{SO}_4)_3 \cdot \text{Rb}_2\text{SO}_4$. The former is prep'd. by allowing to evap. at 10° solns. contg. $\text{Ce}_2(\text{SO}_4)_3$ and Rb_2SO_4 in mol. proportions of 1:4. The crystallographic characteristics are recorded in detail. Its d. is 2.952–2.957. $\text{Ce}_2(\text{SO}_4)_3 \cdot \text{Rb}_2\text{SO}_4$ is obtained by the evapn. at 30° of a soln. contg. $\text{Ce}_2(\text{SO}_4)_3$ and Rb_2SO_4 in the mol. proportions of 1:2. These results show the importance of temp. in governing the particular compd. formed. $\text{Ce}_2(\text{SO}_4)_3 \cdot \text{Rb}_2\text{SO}_4$ is the first anhyd. double sulfate of a rare earth and alkali metal of this type found in the present series of researches.

C. C. DAVIS

Double sulfates of the copper-magnesium group and the sulfonium bases. II. P. C. RAY AND N. RAY. *J. Indian Chem. Soc.* 5, 69–72(1928); cf. *C. A.* 21, 2622.—Double sulfates of the general formula $\text{M}^+\text{SO}_4 \cdot (\text{Me}_3\text{S})_2\text{SO}_4 \cdot 8\text{H}_2\text{O}$, where $\text{M}^+ = \text{Fe}^+, \text{Zn}, \text{Cd}, \text{Mg}, \text{Cu}, \text{Mn}, \text{Ni}$ and Co , are obtained under similar conditions to those used in the prep'n. of the corresponding Et compds. (cf. *C. A.* 21, 2622). By addn. of alc. to concn. aq. solns. of these salts, similar compds. ($+7\text{H}_2\text{O}$) are obtained in the first 6 cases; the Co salt affords a compd. with $6\text{H}_2\text{O}$. The anhyd. salts cannot be obtained since disson. takes place on heating.

B. C. A.

Hexahydrated double sulfates containing thallium. A. E. H. TUTTON. *Proc. Roy. Soc. (London)* A118, 367–92(1928).—In hexahydrated double salts of the type $\text{R}_2\text{M}(\text{SeO}_4)_2 \cdot 6\text{H}_2\text{O}$, where M may be Mg, Zn, Cd, Cu, Ni, Co, Fe^{++} or Mn and R may be K, Rb, Cs or NH_4 , Tl does not eutropically replace the alkali metals. Changes in exterior angles and internal phys. properties are not proportional to the high at. no. of Tl = 81 but the heavier element with its more complicated structure manifests itself in the re-transcendent optical refraction and spectral dispersion. In all other properties Tl resembles the non-eutropic NH_4 salt which is almost identical with the analogous Rb salt. Thus Tl salts are isomorphous with the alkali metal and NH_4 . Tl salts, like the salts of any other individual R-base, show little effect on the crystal characters and the const. of changes of the M-metal.

S. L. B. ETHERXON

Hexahydrated double selenates containing thallium. Completion of the thallium salts and of the whole monoclinic series. A. E. H. TUTTON. *Proc. Roy. Soc. (London)* A118, 393–426(1928).—Results for the double selenates are quite analogous to those for the Tl double sulfates (cf. preceding abstr.). The replacement of S by Se enlarges the unit cells of the structural space lattice and the interfacial angles and the phys. properties are altered but the amts. of the changes are such as accompany isomorphous replace-

ment. In this series also, while NH_4 salts are almost perfectly isostructural with the analogous Rb salts, the Tl salts tend in the same direction but not quite so perfectly. An exceptional property, however, is the high optical refractivity of the Tl salts as compared with other R-base salts of the series. The eutropic progress of the K, Rb and Cs salts is due to the progressive enlargement of the atoms by a shell of 18 electrons, corresponding to the progression in the rare gases. The very mobile extra electron left outside the outermost complete shell accounts for the max. electropositive chem. activity of the alkali metals.

S. L. B. EHTERTON

Cobalticarbonates. G. A. BARBIERI. *Atti accad. Lincei* [6], 7, 747-53 (1928).—During attempts to find the best conditions for the volumetric detn. of K as $\text{K}_2\text{Co}(\text{NO}_2)_6$, it was found that the yellow or orange cobaltinitrites give an intense emerald-green soln. in hot aq. NaHCO_3 . This suggested a relation to the Field-Durrant reaction (cf. *J. Chem. Soc.* 1862, 14; *Proc. Chem. Soc.* 12, 96 (1896); *Ann. chim. phys.* [7], 20, 214 (1900); *Rend. soc. chim. Roma* 3, 68 (1905)), since NaHCO_3 destroyed the cobaltinitroso complex, all NO_2 groups forming NaNO_3 and the Co (remaining tervalent) forming with the CO_3 residue a cobalticarbonate to which is due the green color, and which is identical to that formed by the action of H_2O_2 on Co salts and NaHCO_3 . When a small proportion of insol. alk. cobaltinitrite (e. g., $\text{K}_3\text{Co}(\text{NO}_2)_6$ or $\text{K}_2\text{NaCo}(\text{NO}_2)_6$) and satd. aq. NaHCO_3 are heated and agitated, the yellow powder dissolves to a green soln. Prolonged heating decomp. the green compd., pptg. hydrated Co_2O_3 . If Na_2CO_3 is used instead of NaHCO_3 originally, Co_2O_3 is formed directly. The green compd. is therefore formed only with the HCO_3 ions present. With KHCO_3 instead of NaHCO_3 , no green compd. is formed, and with a sol. cobaltinitrite and excess KHCO_3 , $\text{K}_3\text{Co}(\text{NO}_2)_6$ is pptd., which does not react with KHCO_3 . Therefore in the reaction of NaHCO_3 and an insol. cobaltinitrite, the latter is first transformed into very sol. $\text{Na}_3\text{Co}(\text{NO}_2)_6$, which then reacts with NaHCO_3 , whereas $\text{K}_3\text{Co}(\text{NO}_2)_6$ becomes insol. in the presence of excess KHCO_3 and therefore remains stable. Quant. expts. in which the green soln. was treated independently with excess acidic H_2O_2 , and with excess acidic KMnO_4 , proved that the cobaltinitroso complex is completely decompd. To ascertain whether the green compd. is identical with that formed in the Field-Durrant reaction, solns. were prepd. by the 2 methods, using the same quantities of Co and the H_2O_2 prepn. with the addn. of NaNO_3 to balance that formed in the other soln., and the products were examd. colorimetrically. The 2 solns. were identical, indicating that the same compd. is formed. The electrolytic reaction of Kremann (cf. *Z. anorg. Chem.* 33, 86 (1902)) was then utilized for studying its nature. $\text{Co}(\text{NO}_3)_2$ (5 g.) in 3% H_2O_2 (100 cc.) heated with KHCO_3 (30 g.) until the reaction is complete, introduced in a U-tube and in both branches a soln. composed of equal vols. of 2% K_2SO_4 and KHCO_3 superposed on the liquid and electrolyzed with Pt electrodes, showed by the motion of the green liquid that the Co is in a negatively charged complex ion. Since moreover HCO_3 is indispensable to its formation, it is probable that the green compd. contains Co united by normal valences to CO_3 residues and to OH groups, and by secondary valences to alk. bicarbonate mols., which means a *cobalticarbonate*. The green liquid does not react with excess KSCN and AmOH to give the Vogel reaction (characteristic of bivalent Co, even with excess alk. bicarbonate), and green compds. are formed from compds. contg. tervalent Co, e. g., from cobaltinitrites. Both these facts render improbable the theory of Metzl (*C. A.* 8, 2536). To remove all doubt of tervalent Co in the green compds., the reversibility of the reaction was proved. The green liquids (obtained by the H_2O_2 method) treated with acetylacetone, first slowly in the acid, then rapidly at 60-70°, formed cobaltic acetylacetonate (cf. *Compt. rend.* 129, 304 (1899)). When the green soln. is treated with acetylacetone (3 mols. per atom of Co) and AcOH , and the product is extd. with CHCl_3 , the ext. is an intense green, and on evapn. leaves a cryst. green residue which, recrystd. from CHCl_3 , yields $\text{Co}(\text{C}_6\text{H}_7\text{O}_2)_3$. **Transformation of cobalticarbonates into cobaltiammines.**— NaHCO_3 (50 g.) heated with CoCl_2 (5 g.) in 3% H_2O_2 (100 cc.), filtered, the filtrate heated in an atm. of CO_2 to boiling with NH_4Cl (50 g.), ppts. purpureocobaltochloride $\text{Co}(\text{NH}_3)_5\text{Cl}_2$. With NH_4NO_3 , $(\text{NH}_4)_2\text{CO}_3$, NH_4SCN or $(\text{NH}_4)_2\text{C}_2\text{O}_4$, other cobaltiammines are formed, the prepn. of which is to be described in a subsequent paper. When cobaltinitrites are transformed by NaHCO_3 into cobalticarbonates, there is, between the initial orange color and the final green, a transient violet-red color. The latter becomes persistent if the $\text{Na}_3\text{Co}(\text{NO}_2)_6$ is sufficiently concd. and too great an excess of NaHCO_3 is avoided. Thus $\text{Na}_2\text{Co}(\text{NO}_2)_6$ (3 g.) in water (100 cc.) heated 10 min. with NaHCO_3 (10 g.) gives a permanently violet soln. Toward H_2O_2 and KMnO_4 these violet solns. behave like the green ones. When a large excess of NaHCO_3 is added and the violet solns. are dild. and heated, they turn green. Conversely, the green solns. (both those prepd. from

cobaltinitrites and those from cobaltous salts and H_2O_2) become violet on addn. of cold NaNO_2 . This indicates that in the cobaltic complex, mols. of alk. bicarbonate united by coördination can be replaced by nitrate mols. and *vice versa*. When the violet solns. are concd. and EtOH is added, microscopic examn. shows a mixt. of colorless crystals of alk. salts and violet-red crystals.

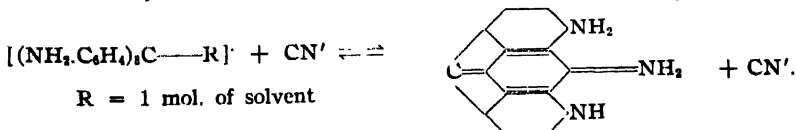

C. C. DAVIS

Thio salts. V. Addition compounds with hexamethylenetetramine. F. RONOLICO. Univ. Firenze. *Atti. accad. Lincei* [6], 7, 660 6(1928); cf. Fernandes, *C. A.* 22, 736.—The cryst. structures of some thio and thioxy salts were detd. to ascertain in what way the structure varies with successive substitutions of O atoms by S atoms. Hexamethylenetetramine addn. compds. were chosen because they are more stable and crystallize better than the normal salts. The following compds. were prepd.: $\text{MgMoO}_4 \cdot \text{C}_6\text{H}_{12}\text{N}_4 \cdot 10\text{H}_2\text{O}$ (cf. Di Capua, *C. A.* 20, 1184), triclinic; $\text{MgMoSO}_3 \cdot 2\text{C}_6\text{H}_{12}\text{N}_4 \cdot 10\text{H}_2\text{O}$, light yellow; $\text{MgMoS}_2\text{O}_2 \cdot 2\text{C}_6\text{H}_{12}\text{N}_4 \cdot 10\text{H}_2\text{O}$, light yellow; $\text{MgMoSO}_3 \cdot 2\text{C}_6\text{H}_{12}\text{N}_4 \cdot 10\text{H}_2\text{O}$, dark red, dimetric $a:c = 1:0.7072$; $\text{MgMoS}_4 \cdot 2\text{C}_6\text{H}_{12}\text{N}_4 \cdot 10\text{H}_2\text{O}$, dark red, monoclinic, $a:b:c = 0.8296:1:0.9764$; $\text{MgWO}_4 \cdot \text{C}_6\text{H}_{12}\text{N}_4 \cdot 10\text{H}_2\text{O}$, same cryst. structure as $\text{MgMoO}_4 \cdot \text{C}_6\text{H}_{12}\text{N}_4 \cdot 10\text{H}_2\text{O}$; $\text{MgWSO}_3 \cdot 2\text{C}_6\text{H}_{12}\text{N}_4 \cdot 10\text{H}_2\text{O}$, yellow; $\text{MgWS}_2\text{O}_2 \cdot 2\text{C}_6\text{H}_{12}\text{N}_4 \cdot 10\text{H}_2\text{O}$, yellow; $\text{MgWSO}_3 \cdot 2\text{C}_6\text{H}_{12}\text{N}_4 \cdot 10\text{H}_2\text{O}$, light yellow; $\text{MgWS}_4 \cdot 2\text{C}_6\text{H}_{12}\text{N}_4 \cdot 10\text{H}_2\text{O}$, orange-yellow, same cryst. structure as $\text{MgMoS}_4 \cdot 2\text{C}_6\text{H}_{12}\text{N}_4 \cdot 10\text{H}_2\text{O}$. Not all these compds. could be examd. crystallographically because they were microcryst. and could not be measured. They were prepd. by adding hot MgCl_2 and $\text{C}_6\text{H}_{12}\text{N}_4$ to the alk. thio salt, the cryst. compd. sepg. on cooling. To prep $\text{MgMoS}_3\text{O}_2 \cdot 2\text{C}_6\text{H}_{12}\text{N}_4 \cdot 10\text{H}_2\text{O}$, however, there was no Mo trisulfurated compd., so ammoniacal $(\text{NH}_4)_2\text{MoO}_4$ was treated with H_2S until a color between the orange of $(\text{NH}_4)_2\text{MoS}_2\text{O}_2$ and the red of $(\text{NH}_4)_2\text{MoS}_4$ was obtained. The crystallographic study showed that with successive replacement of O by S was not accompanied by morphotropic variations in the crystals, indicating the complexity of such thio salts as suggested by Fernandes and Polazzo (cf. *C. A.* 22, 397) on a basis of their colors.

C. C. DAVIS

Chloroform-soluble metal pyridine cyanates. TENNY L. DAVIS AND ALBERT V. LOGAN. Mass. Inst. Tech. *J. Am. Chem. Soc.* 50, 2493-9(1928).—Compds. have been prepd. of $\text{Cu}(\text{NCO})_2$ with 2 and 6 $\text{C}_6\text{H}_5\text{N}$, of $\text{Ni}(\text{NCO})_2$ with 4 and 6 $\text{C}_6\text{H}_5\text{N}$, of $\text{Co}(\text{NCO})_2$ with 2 and 6 $\text{C}_6\text{H}_5\text{N}$, of $\text{Cd}(\text{NCO})_2$ with 2 and 6 $\text{C}_6\text{H}_5\text{N}$, of $\text{Zn}(\text{NCO})_2$ with 2 $\text{C}_6\text{H}_5\text{N}$ and of AgNCO with 1 $\text{C}_6\text{H}_5\text{N}$, by adding $\text{C}_6\text{H}_5\text{N}$ to a soln. of equiv. quantities of KNCO and the metal salt in H_2O until a slight excess was present; the ppt. was extd. with CHCl_3 and the filtrate allowed to evap. spontaneously; the compds. contg. less $\text{C}_6\text{H}_5\text{N}$ were obtained by leaving the satd. compds. uncovered in watch glasses for periods varying from 2 days to 1 week. $\text{Cu}(\text{NCO})_2 \cdot 6\text{C}_6\text{H}_5\text{N}$ forms azure-blue prisms, which retain their color and form in an atm. of $\text{C}_6\text{H}_5\text{N}$; exposed to the air, the crystals change to a pale blue or bluish lilac powder of the $2\text{C}_6\text{H}_5\text{N}$ deriv.; after several months or after heating to 100° for a few hrs., all the $\text{C}_6\text{H}_5\text{N}$ is removed. $\text{Ni}(\text{NCO})_2 \cdot 6\text{C}_6\text{H}_5\text{N}$ is a lighter blue than the Cu deriv.; it loses $\text{C}_6\text{H}_5\text{N}$ to form a pale blue powder of the $4\text{C}_6\text{H}_5\text{N}$ deriv. $\text{Co}(\text{NCO})_2 \cdot 6\text{C}_6\text{H}_5\text{N}$ yields a blue soln. in CHCl_3 which turns lilac or pink if the temp. is lowered or if $\text{C}_6\text{H}_5\text{N}$ is added. By adjusting the quantity of excess $\text{C}_6\text{H}_5\text{N}$ in such a soln., a liquid may be secured which changes color with very moderate changes of temp. $\text{Cd}(\text{NCO})_2 \cdot 6\text{C}_6\text{H}_5\text{N}$ is colorless; the colorless $\text{Zn}(\text{NCO})_2 \cdot 2\text{C}_6\text{H}_5\text{N}$ does not lose an appreciable quantity of $\text{C}_6\text{H}_5\text{N}$ after a week's exposure; in an atm. of $\text{C}_6\text{H}_5\text{N}$ it deliquesces to form a sirupy liquid. $\text{AgNCO} \cdot \text{C}_6\text{H}_5\text{N}$ also deliquesces in an atm. of $\text{C}_6\text{H}_5\text{N}$. The Cu and Co hexapyridine derivs. raise the b. p. of CHCl_3 about 6.5 times as much as would be expected if they were undissociated mols. C. J. W.

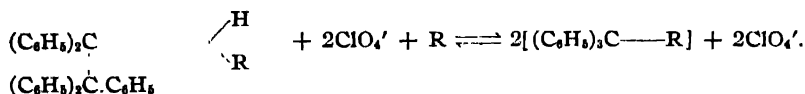

Color, molecular weight and electrolytic character of triphenylmethane derivatives. I. LIFSCHITZ and GEERT GIBBS. Rijks Univ. Ber. 61B, 1463-91(1928); cf. *C. A.* 20, 1231.—The transposition of *di-* and *tri*aminotriphenylmethane derivs. into isomeric dyestuff salts takes place as follows: $(\text{NH}_2 \cdot \text{C}_6\text{H}_4)_3\text{C} \cdot \text{CN} \rightleftharpoons [(\text{NH}_2 \cdot \text{C}_6\text{H}_4)_2\text{C}] \cdot \text{CN}$. The left-hand member of this equation is a colorless nonelectrolyte and the right-hand member a colorless or weakly colored electrolyte. This in turn undergoes a transposition in which a dyestuff cation is formed as follows:

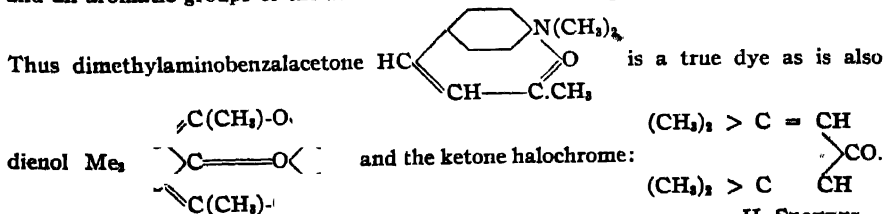

To investigate more fully the nature of these substances and explain the presence or absence of color, the following compds. are prepd.: *tri-p-anisylmethane*, m. 49° ; *tri-*

p-anisylcarbinol, m. 82°; *di-p*-anisylphenylmethane (I), m. 99–100°; *di-p*-anisylphenylcarbinol (II); *p*-anisyl-diphenylcarbinol (III); *tri-p*-anisylmethyl perchlorate, carmine-red crystals, m. 193°; *di-p*-anisylphenylmethyl perchlorate (IV), m. 210°; *p*-anisyl-diphenylmethyl perchlorate, m. 191°; triphenylmethyl perchlorate (V), m. 150°; *tri-p*-anisylacetoneitrile, m. 128°; *di-p*-anisylphenylacetoneitrile (VI), m. 33–34°; *p*-anisyl-diphenylacetoneitrile (VII), m. 117–18°; *tri-p*-anisylmethyl thiocyanate; *di-p*-anisylphenylmethyl thiocyanate (VIII), colorless crystals, m. 112°; *p*-anisyl-diphenylmethyl thiocyanate, m. 72°; triphenylmethyl thiocyanate, m. 137°; triphenylmethyl chromate, m. 145°; triphenylmethyl azide, m. 65°; malachite green azide (IX), m. 118–19°; *tri-p*-anisylmethyl ferrocyanide (X); *di-p*-anisylphenylmethyl ferrocyanide, m. 192°; anisyl-diphenylmethyl ferrocyanide, colorless crystals contg. 2 mols. CHCl_3 , driven off at 120–30°, m. 238°; triphenylmethyl ferrocyanide, m. 280°; *p*-dimethylaminobenzal acetone (XI). II is prepd. by action of PbO_2 on I, III by the reaction between anisic acid methyl ester and phenyl magnesium bromide, IV by the action of $(\text{CH}_3\text{CO})_2\text{O}$ and HClO_4 upon the carbinol, V by the action of HClO_4 upon a soln. of the corresponding carbinol in $(\text{CH}_3\text{CO})_2\text{O}$, VI from the interaction of benzoyl cyanide, anisole and AlCl_3 , VII by action of $\text{Hg}(\text{CN})_2$ upon the MeCl , VIII by action of KCN on the soln. of the corresponding perchlorate in CHCl_3 , IX by action of Na azide on the chloride, X by action of $\text{K}_4\text{Fe}(\text{CN})_6$ upon the perchlorate. All the complex ferrocyanides are insol. in H_2O , sol. with difficulty in most org. solvents, very easily sol. in CHCl_3 . XI exists in 2 forms. From the dichromate red alc. soln., orange red to brick red crystals are obtained (m. 128°). Crystd. from boiling ligroin, orange colored plates sep., while from boiling water bright yellow plates are obtained (m. 135°). On dissolving the yellow crystals in AcOH , a red crust is formed on evapn., but H_2O reconverts this into the yellow form. The bright yellow modification is darkened by ultra-violet rays. Spectrographic behavior, mol. wt., cond. and other phys.-chem. properties are detd. for all the above compds. As typical colored carbonium salts, the perchlorate of triphenylcarbinol and its *p*-methoxy homologs are taken, and as colorless derivs. of the same carbinol, the cyanide, thiocyanate, ferrocyanide, azide and chromate are investigated. In studying color characteristics it is found that the color of the solns. depends upon the solvent, the concn. and the temp., and for a given substance the intensity of the color increases with change of solvents in the following order: Et_2O , alc., acetone, $\text{C}_6\text{H}_5\text{NO}_2$, CH_3CN , camphor, CHCl_3 . In some cases heat intensifies the color or even gives a colorless soln. color, but on cooling this effect is lost again. In characteristic dyestuff salts of the malachite green series this heat effect was not previously encountered, but careful investigation of the azides, ferrocyanides and thiocyanates of malachite green indicates the existence of a colorless form which on heating in soln. becomes colored. Solns. of malachite green, therefore, contain an equil. between a true dyestuff salt and a colorless form. If to one of these solns. the salt $[\text{Hg}(\text{CN})_2, \text{Hg}(\text{CNS})_2]$ is added, an intense coloration appears due to the formation of a complex Hg dyestuff salt. With a Hg rosaniline cyanide the dyestuff compd. has the formula $[(\text{NH}_2, \text{C}_6\text{H}_4)_3\text{C}-\text{R}]^+ [\text{Hg}(\text{CN})_2]^-$, is intensely colored and a strong electrolyte, while the leucocyanide has the formula $(\text{NH}_2, \text{C}_6\text{H}_4)_3\text{C}^+\text{CN}^--\text{Hg}(\text{CN})_2$, is completely colorless, and a nonelectrolyte. This colorless compd. is converted into the colored compd. only by ultra-violet radiation; therefore there is no equil. between the 2 salts in soln. The cyanides and azides of the triphenylcarbinols and their methoxyl homologs behave similarly, but are always colorless and nonelectrolytes and remain so on addn. of heavy metal salts. By ultra-violet radiation, however, the leuco compd. is converted first into the colorless but more or less stable electrolyte, which either by hydrolysis or constitutive differentiation comes into equil. with the colored form, thus: $\text{Ar}_3\text{C}^+\text{X}^- \rightleftharpoons [\text{Ar}_3\text{C}-\text{R}]^+\text{X}^- \rightleftharpoons [\text{Ar}_3'\text{C}-\text{R}]^+\text{X}^-$. Extended mol. wt. detns. are made. The cyanides of triphenyl-, anisyl-, diphenyl-, dianisyl-, phenyl- and trianisylcarbinols show normal mol. wt. in their colorless solns. in all solvents. With the thiocyanates, however, this is true only in CHCl_3 solns., while in alc. solns. the exptl. results are only 60–75% of the theoretical, and the substances are therefore dissocd., the dissocn. decreasing as the concn. rises. Cond. measurements show these compds. to be good electrolytes. They are in sharp contrast to the typical colored carbonium salts which show strong assocn. Thus the stable perchlorates of methoxylated triphenylcarbinol give the following results in CHCl_3 : $(\text{C}_6\text{H}_5)_3\text{C}(\text{C}_6\text{H}_4\text{OCH}_3)_3\text{ClO}_4$, mol. wt. theoretical = 372.5, found: 0.96% soln. —591, 1.50% soln. —627, 2.03% —704, 2.51% —703, 3.27% —779, 4.14% —856; while for $(\text{CH}_3\text{O}, \text{C}_6\text{H}_4)_3\text{C}(\text{C}_6\text{H}_5)\text{ClO}_4$, mol. wt. theoretical is 402.5 and found is, for 0.96% soln. —705, 1.59% —745, 3.00% —848, 3.70% —975. With increasing concn. the color intensity also increases. In acetone, the solns. are much less strongly colored and show dissocn. at all concns. and to an extent independent of concn., the mol. wt. found being about 75%

of the theoretical. Mol. wt. detns. in $C_6H_5NO_2$ give for $(CH_3O.C_6H_5)_3C.ClO_4$ by the cryoscopic method 261 or about 60% of the theoretical, and by the ebullioscopic method 329 or about 76% of the theoretical. The strongly colored solns. of the perchlorates therefore contain assocd. polymolar salts, whose mol. wt. approaches the normal more closely the more weakly absorbing is the solvent. Cond. measurements are made at 25° and show that the cyanides and azides of the triphenylcarbinols and methoxytriphenylcarbinols, as well as the leucocyanides of the di- and triaminotriphenylmethane dyestuffs, are nonelectrolytes under all conditions. Only by ultra-violet radiation is ionization produced. On the other hand malachite green azide is strongly electrolytic in character. In alc. soln. its mol. cond. is 10.51 at 250 l. and the color is blue-green. Much more weakly colored is the soln. in $C_6H_5NO_2$, its cond. being 0.33 at 250 l. The addn. of 2 mols. of $Hg(CN)_2$ to the $C_6H_5NO_2$ soln. of 1 mol. of this azide produces a deep dark green color and a cond. of 13.15 at 250 l. The action of the Hg compd. is to form a complex anion. This is in contrast to the cyanide where no disson. occurs, and in which the C-CN bond is homopolar, while in the azide the C-N₃ bond is either heteropolar and ion producing or is made up of 2 colorless mol. types of azides, one of which is purely homopolar (similar to triphenylmethyl azide) while the other contains an ion-producing bond. The ferrocyanides of triphenyl and methoxy-triphenyl carbinol give almost colorless solns. but show considerable cond. The colorless ferrocyanides give colorless or very weakly colored triarylmethyl ions $[Ar_3C-R]^+$ and behave in this respect like the corresponding thiocyanates which are much more sol. The cond. of $(C_6H_5)_3C.CNS$ at 100 l. is 4.84, and of $(C_6H_5)_2C(C_6H_4.OCH_3).CNS$ is 4.78 (in abs. alc.). With these substances the cond. does not reach its full value until after 24 hrs. unless the solns. are heated. Ultra-violet radiation produces decompn. and polymerization products of *thiocyanogen*. Addn. compds. with $Hg(CN)_2$ or $Hg(CNS)_2$ show high cond. Thus in alc. soln. $(C_6H_5)_3C.CNS + 1$ mol. $Hg(CN)_2$ has a cond. at 100 l. of 10.56, the soln. being colorless. The cond. of the typical colored carbonium salts, the perchlorates, is much higher. Thus in alc. soln. the golden orange trianisylcarbonium perchlorate has a mol. cond. of 50.82 at 200 l., and the colorless soln. of dianisylphenylcarbonium perchlorate has a cond. of 52.40 at 200 l. In acetone soln. the trianisyl compd. has a cond. of 126.9. Similar values are obtained in acetonitrile, but lower values in $C_6H_5NO_2$. The temp. coeff. of cond. is measured for the carbonium salts and found to be about the same as that for the NH_4 salts. No relation between color and cond. is encountered in these compds. Conclusion: The colored complex carbonium salts are ternary electrolytes whose cations are formulated as follows:

The expts. thus show that there are colorless or weakly colored triarylmethyl salts whose colorless or weakly colored solns. are electrolytic conductors. Measurements show that the colorless solns. of the triarylmethane derivs. contain monomolar or dissond. substances. The simple benzoid triarylmethyl ions $[Ar_3C-R]^+$ are normally colorless or weakly colored. The intensely colored carbonium salt solns. contain assocd. or higher complex salts or ions. The mol. wt. increases at a rate parallel to color intensity, while color and cond. are independent. The colorless and colored triarylmethyl salts are in general not isomeric. For the occurrence of absorption as in dyestuffs, an aromatic character is unnecessary. All 3 benzene nuclei of triphenylmethane derivs. and all aromatic groups of the *ketone halochromes* can be replaced by aliphatic groups.

7—ANALYTICAL CHEMISTRY

WILLIAM T. HALL

Microchemical reactions (with hexamethylenetetramine sulfate and with piperazine.) A. MARTINI. *Mikrochem.* 6, 28-33(1928).—Addn. of $(\text{CH}_2)_6\text{N}_4\cdot\text{H}_2\text{SO}_4$ and NH_4CNS solns. to a soln. of CoCl_2 yields glistening blue, triclinic prisms of a complex, non-ionized compd. Under similar conditions CuCl_2 yields light yellow, triclinic tables, ZnCl_2 a mass of thin, white needles, FeCl_2 light red crystals, VOCl_2 light red hexagons, InCl_3 reddish white, tetragonal prisms and $(\text{NH}_4)_2\text{MoO}_4$ red, hexagonal crystals or yellow prisms. A mixt. of SbCl_3 and NaI yields with an acetone soln. of piperazine microscopic, monoclinic, yellow tablets and prisms. Under similar conditions BiCl_3 gives intense red crystals isomorphous with the Sb compd. AuCl_3 , NaBr and piperazine produce orange-yellow to red microscopic prisms. B. C. A.

Nomography. O. LIESCHE. *Chem. Fabr.* 1928, 161-4—Methods of constructing charts for the elimination of calcn. are discussed, and 2 types of chart for reading percentage of S from the weight of substance taken and of BaSO_4 obtained are given. B. C. A.

Chemical x-ray spectrography. LARS THOMASSEN. *Statens Raststoffkomité Publ.* No. 21, 108 pp., Oslo 1926 (Norwegian with English summary); *Mineralog. Abstracts* 3, 460—Detailed directions are given for detecting chem. elements by x-ray spectrum analysis. Tables give the angles of reflection from halite of the rays from various elements. By this method 0.5% of an element is readily detected or 0.1% with special exposures. Intensities of lines afford an approx. quant. estimation. J. F. SCHAIER

The electrodeposition of traces of metals and spectral analysis of the same. EDMOND BAYLE AND LUCIEN AMY. *Bull. soc. chim.* 43, 604-24(1928); cf. C. A. 21, 3579. —A continuation of the work on the detection of traces of metals by making micro-depositions and then taking spark-spectrographs of the cathodes. The traces are deposited electrolytically on cathodes of Cu or Zn from solns. contg. as little as 10^{-3} to 10^{-7} parts in any vol. of soln. The sensitivity on Cu cathodes are: Au, 10^{-6} ; Ag, 10^{-4} ; Pb, 10^{-10} ; Sb, 10^{-4} ; Co, 10^{-6} ; Ni, 5×10^{-7} ; Fe, 10^{-7} ; Cu, 10^{-3} ; Mn, 10^{-10} ; Zn, 10^{-3} ; on Zn: Ag, 10^{-6} ; Cu, 10^{-7} grams. The presence of alkali, alk. earth and NH_4 salts causes no interference. The no. of lines produced in the spectra gives a measure of the amt of salt present. The app. is described. C. J. BROCKMAN

The applicability of the analytical quartz lamp for mixtures of solid substances. FR. HEIN AND W. RETTER. *Univ. Leipsic. J. prakt. Chem.* 119, 368-70(1928).—The fluorescence produced with the aid of ZnO , UO_2SO_4 or anisil by substances like diphenyl disappears when mixed with considerable CuO , Pb_3O_4 , CrO , Fe_2O_3 , HgS or azobenzene. A table is given showing how much of these substances must be present in order to prevent the characteristic fluorescence. W. T. H.

New method of potentiometric analysis. II. Determination of halogen and of silver. THEODOR HECZKO. *Z. anal. Chem.* 74, 289-308(1928).—The principle underlying these titrations is the same as has been described for the potentiometric titration of Fe^{++} with KMnO_4 . In the strongly stirred soln. to be titrated, there is placed a wire of Ag and a rod of a non-conductor of such a nature that it will readily absorb aq. solns. The latter at one end is wound with another piece of Ag wire. Before beginning the expt. this rod is entirely submerged in the soln. and is then withdrawn so that the enveloping wire is entirely above the soln. The 2 Ag wires are connected through a galvanometer and the titration is made. Every addn. of reagent causes a jump in the current. The quotient, increase in the galvanometer reading \div cc. added, reaches a maximum at the end point. Sometimes it is better to measure the residual current for detg. the end point. To make the soln. more conductive, 10 cc. of 50% NH_4NO_3 are added to 150-200 cc. of soln. which is a suitable vol. Pieces of pine wood, boiled for 15 min. in 300 cc. of water, serve as the non-conducting rod. For the detn. of halogen with AgNO_3 soln., the wire about this wood should be connected with the negative pole of the galvanometer but with the positive pole when the reverse titration is made. Minute details are given for the titration of Ag^+ , Cl^- , Br^- and I^- and for the titration of halogens in the presence of one another. W. T. H.

Potentiometric micro-titrations. E. ZINTL AND K. RETZ. *Z. anal. Chem.* 74, 330-42(1928).—The end point of a titration is generally detd. by the change in direction of the titration curve. This change in direction does not, however, in pptn. analyses correspond exactly to the equivalence point which it is desired to find. The error is proportional to the vol. of soln., the soly. product of the ppt. and it is inversely proportional to the square of the normal concn. of the soln. In ordinary titrations, or when

the N concn. of the soln. is equal to or greater than the sq. root of 32 times the soly. product, the error is negligible but in micro-titrations it can become very serious. In titrating Cl^- with $0.1\ N\ AgNO_3$ and a final vol. of 100 cc., this error is only 8×10^{-4} cc. but in titrating Cl^- with $10^{-4}\ N\ AgNO_3$ soln. and a final vol. of 10 cc., the error is 0.8 cc. Accurate titrations are described in a final vol. of 10 cc. of Cl^- with 0.001 $N\ AgNO_3$ and of I^- with 0.0001 $N\ AgNO_3$. The theoretical error is 0.008 cc. in the former case and 8×10^{-7} cc. in the latter. Contrary to the statements of Mislowitz and Vogt (*C. A.* 20, 773) it was found possible to det. Cl^- in serum by direct titration, after addn. of dil. H_2SO_4 or after coagulation of the albumin with picric acid or KH_2PO_4 . Titrations of Br^- and of trivalent As with 0.001 $N\ KBrO_3$ are also described. The micro-titration of As is nearly as sensitive as the Marsh-Liebzig test. When 0.002 mg of As was titrated with 0.0001 $N\ KBrO_3$, the results were 8% too high. Traces of As in Cu solns. can be detd. very easily by micro-titration.

W. T. H.

Thymolphthalein as indicator for titrimetric estimation of carbon dioxide. C. J. SCHOLLENBERGER. Ohio Agr. Expt. Sta. *Ind. Eng. Chem.* 20, 1101(1928).—When CO_2 is absorbed in $Ba(OH)_2$ the excess of the latter is commonly titrated with acid, phenolphthalein being used as indicator. A much sharper end point is obtained with thymolphthalein, which is recommended.

W. T. H.

Use of picric acid as an artificial standard in the colorimetric estimation of silica. E. J. KING AND C. A. LUCAS. Univ. of Toronto *J. Am. Chem. Soc.* 50, 2395-7(1928).—When dil. SiO_2 solns. are treated with an acid and $(NH_4)_2MoO_4$, a color is developed which can be matched exactly by dil. picric acid solns. Expts. show that the color of a soln. contg. 50 mg. of SiO_2 per l. when treated with the reagents of Diénert and Wandenbuleke is equiv. to a soln. contg. 25.6 mg. of pure, dry picric acid. This amt. of picric acid is less than that hitherto used.

Estimation of nitrogen. A combined Kjeldahl and nesslerization method. M. R. RAMASWAMI SIVAN AND M. SANYASI RAJU. *Madras Agr. Dept., Yearbook* 1926, 6-10 (1927).—About 0.1 g of the finely ground sample is digested in a Kjeldahl flask with 2-3 cc. strong H_2SO_4 and 1 g K_2SO_4 under a direct flame until colorless, with a small spiral of Pt as a catalyst. Cool; neutralize with NaOH; ppt. Ca, etc., by shaking with a few crystals of $K_2C_2O_4$; dil. to known vol; filter through dry paper; and det. N by the usual Nessler method. Tables are given showing comparative results obtained with the Kjeldahl and modified Nessler methods on soils and several org. compds.

K. D. JACOB

Diphenylcarbazide as a test for chromium. NORMAN M. STOVER. *J. Am. Chem. Soc.* 50, 2363-6(1928).—The diphenylcarbazide test of Cazeneuve, which has also been used by Brandt and by Snoddy, is much more sensitive than the test for Cr with ether and H_2O_2 . In the analysis of the third group of the regular qual. scheme, the test can readily be applied by taking the filtrate obtained after treating Fe^{++} , Cr^{+++} , Zn^{++} and Al^{+++} with NaOH and Na_2O_2 , making acid with AcOH and adding 2 cc. of reagent prepd. by dissolving 0.2 g. of diphenylcarbazide in 10 cc. of glacial AcOH and dilg. with 100 cc. of 95% alc. The test is more sensitive when H_2SO_4 is used instead of AcOH.

W. T. H.

Modified confirmatory test for aluminum. ELIAS H. PAÑGANIBAN AND FLOR-ENCIO A. SOLIVEN. Univ. of the Philippines. *J. Am. Chem. Soc.* 50, 2427-8(1928).—By placing a few asbestos threads in the paper filter recommended by A. A. Noyes in his method of applying the Thénard test for Al, and then igniting the asbestos rather than paper, the test becomes more sensitive and it is not necessary to wash the $Co(AlO_2)_2$ ppt. free from Na salts as in the Noyes' scheme.

W. T. H.

Rapid determination of magnesium. L. GALIMBERTI AND E. ZOCCHEDDU. Lab. Ricorche chim. Bonifica di Santa Gilla, Cagliari. *Ann. chim. applicata* 18, 286-8(1928).—The new method is simpler and more rapid than any so far proposed and gives excellent results. It depends upon the fact that Mg may be detd. alkalimetrically, whether or not alk. chlorides or sulfates are present. *Procedure*—To an accurately measured vol. of soln. add drop by drop an excess of cold 0.1 N NaOH (with Me orange as indicator), make up to 250 cc. with water, agitate, let stand a few min., filter and titrate 100 cc. of filtrate with 0.1 N HCl (Me orange). Many operators have better success using phenolphthalein in the final titration.

C. C. DAVIS

Notes on the detection of tin, zinc and chlorine. EDWIN EGGRIWE. *Z. anal. Chem.* 74, 225-31(1928).—In the qual. scheme, Fe is commonly used to reduce Sn^{++++} to Sn^{++} but the presence of the Fe^{++} interferes with most color reactions that could be otherwise used for the detection of the Sn^{++} . *Coerulein* and *diazinegreen S* (K), however, can be used in the presence of Fe^{++} . In concd. HCl, 1 drop of $SnCl_4$ soln.

contg. 0.01 mg. of Sn gives a distinct fluorescence with the former but unfortunately the dyestuff is no longer on the market. The latter dye gives a blue soln. in HCl but a trace of Sn^{++} causes the formation of red safranin, a violet shade being shown immediately. To test for Sn, dissolve a ppt. of Sb_2S_3 and SnS_2 in concd. HCl, keeping the vol. small, and reduce with Fe. Add 5 cc. of aq. 0.01% soln. of the dye, which has been turned a clear blue by the addn. of HCl. To detect Zn by a color reaction, metanil yellow or Orange IV can be used in 0.01% aq. soln. In solns. contg. HCl these dyes give a red color which disappears when $\text{K}_3\text{Fe}(\text{CN})_6$ and a little Zn^{++} are present. To use this test in the qual. scheme after the Zn, Al and Cr have been sepd. from the other members of Group III by the use of NaOH and Na_2O_2 , it is first necessary to reduce CrO_4^{--} , which is best accomplished by H_2O_2 in acid soln. Another dye that can be used for detecting Zn is diethylaniline. In H_3PO_4 soln. this dyestuff shows a pale yellow color but when $\text{K}_3\text{Fe}(\text{CN})_6$ and a little Zn^{++} are added, the color turns brownish or reddish. In 18 N H_2SO_4 soln., this dye is dark yellow in color. When $\text{K}_3\text{Fe}(\text{CN})_6$ and a little Zn are added, a brownish red color develops and a ppt. forms. For the detection of Cl^- an aq. soln. of *Acid Fuchsin S (A)* can be used. Dip filter paper into the soln. to prepare suitable test papers. The red color changes to yellow when acted upon by Cl_2 developed from as little as 0.05 mg. of NaCl by treatment with KMnO_4 and H_2SO_4 . Br_2 and NO_2 interfere with this last test, as well as ClO^- and BrO^- . W. T. H.

Ceric sulfate as a volumetric oxidizing agent. VII. Determination of vanadium in the presence of chromium, tungsten and iron. H. H. WILLARD and PHILENA YOUNG. Univ. Mich. *Ind. Eng. Chem.* 20, 972-4(1928); cf. C. A. 22, 2123.—Furman (C. A. 22, 2900) described the titration of $\text{V}_2\text{O}_5^{++++}$ solns., with $\text{Ce}(\text{SO}_4)_2$ and applied the method to the analysis of Fe-V. The present paper was written before the publication of F.'s paper and applies the method to the analysis of steels contg. Cr, V and W. WO_3 is filtered off, dissolved in NaOH soln. and added to the main soln. from which it is not reprecipitated, as might be expected although it has been known for some time that Na^+ interferes with the pptn. of WO_3 . W. T. H.

The detection of vanadium in the systematic course of analysis. J. RÖHL. Nürnberg höhere technischen Staatslehranstalt. *Z. anal. Chem.* 74, 342-5(1928).—It is recommended in some textbooks to test for V in the soln. after pptn. of sulfides of the third group with $(\text{NH}_4)_2\text{S}$ but this is unsatisfactory because the sulfide ppt. tenaciously retains a considerable part of the V and, moreover, the pptn. of V_2S_5 from the $(\text{NH}_4)_2\text{S}$ soln. by adding acid is always incomplete. It is better to provide sufficient Fe^{+++} and ppt. with a very slight excess of NH_4OH . It is not even necessary to make sure that all of the V is in the quinquivalent condition because $\text{Fe}(\text{OH})_3$ adsorbs $\text{V}_2\text{O}_5^{++++}$. When a ppt., consisting possibly of hydroxides of Fe, Cr, Al, U, V and Ti, is to be analyzed, it is well to treat the ppt. first with hot NaOH soln. to dissolve out the V and the Al. Then make a portion of the soln. strongly acid and test for V by the H_2O_2 reaction and for Al in the usual way. Next digest the original ppt. with Na_2CO_3 to dissolve out the UO_2 and apply the ferrocyanide test. Fusion of the remainder of the ppt. with NaKCO_3 gives water-sol. CrO_4^{--} ; Fe can be detected by dissolving a little of the ppt. in HCl and testing with CNS^- and the Ti can be detected in H_3PO_4 soln. by the H_2O_2 test. By the addn. of NH_4F it can be proved that residual V does not give the test for Ti. W. T. H.

Determination of vanadium in steel. A. T. ETHERIDGE. *Analyst* 53, 423-8 (1928).—Dissolve 5 g. of steel in HCl with a little HNO_3 . Evap. and treat the HCl soln. with ether, carrying out the Rothe method for removing FeCl_3 substantially as recommended by Bauer and Deiss (C. A. 16, 1920; cf. Hall and Williams (C. A. 16, 1206). It is necessary to use a little H_2O_2 in the ether-HCl mixt. used for washing the ethereal FeCl_3 soln. in order to remove traces of V from the ether. Take the aq. soln., evap. off ether, add HNO_3 to oxidize org. matter and evap. with H_2SO_4 at a low temp., in order to prevent as far as possible the formation of anhyd. sulfates which are difficult to redissolve. Dil. with water, filter off SiO_2 , add 1 g. of hydrazine sulfate and purify the V soln. electrolytically as recommended by Cain. Filter, remove traces of Hg as HgS and oxidize with strong KMnO_4 . Then reduce with SO_2 , remove the excess of reductant and titrate hot with KMnO_4 . This method has been found accurate with samples contg. 0.1-0.85% V. If more than 0.75 g. of Cr is present it is a tedious process to remove all of the Cr electrolytically. This difficulty can be overcome by electrolyzing the soln. in sep. portions, providing sufficient app. is available, or the V can be pptd. by cupferron, the ignited ppt. dissolved in H_2SO_4 and electrolyzed. W. T. H.

The separation of molybdenum from vanadium in steel analysis. J. KASSLER. *Z. anal. Chem.* 74, 276-89(1928); cf. C. A. 22, 556.—If sufficient ferrous salt is present

all of the V can be pptd. with the Fe on adding an excess of NaOH soln. and the Mo can then be detd. in the filtrate by pptn. with Pb salt or colorimetrically by the reaction with SnCl₂. For steels contg. less than 3% Mo take 4 g. of sample and dissolve in 100 cc. of 6 N HCl. When the sample is nearly all dissolved, add 70 cc. of 5% KClO₃ soln. Heat for 2 min. to accomplish oxidation and then boil for 5 min. to expel excess Cl₂. If SiO₂ separates, filter it off. Neutralize the free acid with NaOH soln. and add 25 cc. of 20% Na₂S₂O₃ soln. to reduce a part of the Fe⁺⁺⁺ to Fe⁺⁺. Pour the boiling hot soln. into 120 cc. of hot 24% NaOH. Filter and use an aliquot part of the filtrate for the Mo detn. If more than 3% Mo is present use only 1 g. of sample. In this case, instead of reducing a part of the Fe, add 3 g. of FeCl₂ in order to get a proper ratio of Fe⁺⁺: Fe⁺⁺⁺ for the complete pptn. of the V.

W. T. H.

Analysis of fresh iron oxide. J. H. STIJNS. *Hel Gas* 48, 324-6(1928).—Most Dutch iron oxides contain considerable phosphate (up to 5%) which has to be considered in the gravimetric detn. of Fe.

B. J. C. VAN DER HOEVEN

Notes on the chemical analysis of pitchblendes. EDUARD KÖRNER AND FRIEDRICH HECHT. Univ. Vienna. *Monatsh.* 49, 438-43, 444-59(1928).—This research records the results of a great deal of careful analytical work on the analysis of several samples of pitchblende. The results show that the procedure recommended by C. W. Davis (*C. A.* 20, 1778) is satisfactory although several minor modifications are suggested. There are still some points to be cleared up that will require work with synthetic mixts. Considerable attention was paid to the detn. of Th, because according to the theory of G. Kirsch, Th is a decompn. product of an hypothetical isotope of U of at. wt. 236, so that the age of a sample of pitchblende can be estimated to some extent by the quantity of Th present. Davis could find no Th in the pitchblende he analyzed but in the samples now studied the presence of about 0.01% Th was established although the theory of Kirsch would require 10 times as much. It is not yet clear whether this is due to a faulty method of analysis or not. The ratio of Pb: U, which is of importance in detg. the age of the mineral, was established very satisfactorily by the method of analysis used, which is so complicated that the original papers must be consulted for details.

W. T. H.

The thorium content of Katanga pitchblende. An analytical chemistry investigation. FRIEDRICH HECHT AND EDUARD KÖRNER. Univ. Vienna. *Monatsh.* 49, 460-75(1928).—This paper contains many interesting comments on the difficulties attending the detn. of the Th content of pitchblende. The method of C. W. Davis (*C. A.* 20, 1778) requires modification when a small quantity of Th (say 0.01%) is to be detd. because when Pb is pptd. as PbSO₄, as it is at the start of the Davis method, a little ThO₂ is occluded by the ppt. After the electrolysis of the HNO₃ soln. and deposition of PbO₂ on the anode, the residual soln. should be combined with the filtrate from the original PbSO₄ ppt. so that it is available for the subsequent detn. of Th. The sepn. of Th as fluoride is better than as subphosphate because the Th(H₂P₂O₆)₂ ppt. apparently occludes U and other elements. Moreover, the assumption that the subphosphate is changed completely to ThP₂O₇ on ignition does not appear to be true as the ppt. weighs too much. It has been noticed that Pb salts from radioactive minerals show a greater tendency to hydrolyze than ordinary Pb salts. Studies were carried out in the attempt to show the presence of Th⁺⁺⁺ was the cause of this peculiarity, but in the light of all the results obtained, this explanation does not appear to be reasonable, although it is probable that when the electrolysis of the HNO₃ soln. is carried out in accordance with the method of Davis, the PbO₂ deposit always contains a little PbSO₄ and often some ThO₂. With respect to the detn. of U, the method of Schoep and Steinkuhler (*C. A.* 16, 3828) is imperfect when large quantities of U and P are present unless several pptns. are made. Although the presence of 0.01-0.02% of ThO₂ in pitchblende has been demonstrated by this work, it is pretty clear that this small quantity shows the falsity of the theory of Kirsch with respect to Th being one of the decompn. products of an isotope of U.

W. T. H.

Determination of available sulfur in roasted blendes. EDGAR BEYNE. *Anal. chim. anal. chim. appl.* 10, 221-5(1928).—It is often the practice to det. total S and compute the S present as sulfate from the Pb, Ba, Ca and Mg content of the roasted ore. This is likely to lead to error, as Hassreidter has quite recently shown. It is better to det. the available S by oxidizing the H₂S formed by treatment with SnCl₂ and HCl. The S present as ZnSO₄ can be detd. by extg. with hot water and detg. the Zn.

W. T. H.

The determination of nitrates. II. L. SZEBELDÉY. *Z. anal. Chem.* 74, 232-5(1928).—S. has shown (*C. A.* 22, 1745) that nitrates can be titrated in concd. H₂SO₄ soln. by means of FeSO₄ soln. and in this paper the reaction was tested in the presence

of Na^+ , NH_4^+ , Mg^{++} , Ca^{++} , Sr^{++} , Ba^{++} , Ni^{++} , Co^{++} , Al^{+++} , Cr^{+++} , Mn^{++} , Zn^{++} , As^{+++} , AsO_4^{---} , Sb^{+++} , Ag^+ , Pb^{++} , Hg^+ , Hg^{++} , Cu^{++} , Bi^{+++} and Cd^{++} ions. Interference was noted with the following ions only. Pb^{++} , Hg^{++} and Bi^{+++} salts cause white ppts. of sulfates as does Ba sometimes by diln. of the H_2SO_4 on adding the reagent. It is advisable to have a comparison tube with a similar ppt. in order to match the end point. Ni^{++} causes the color to be more greenish at the end point. Cu^{++} causes the color to be grayish blue at the end point and reddish blue when an excess of reagent is added. Co^{++} and Cr^{+++} interfere enough to make the titration worthless. Hg^{++} causes low results and pure arsenite solns. cannot be titrated accurately unless small particles of As are in suspension in the liquid. W. T. H.

Colorimetric determination of sulfuric acid. JUNZŌ YAMAZAKI. Tokyo Imp. Inst. *Bull. Chem. Soc. Japan* 3, 173-80(1928).—In the presence of dil. HCl, alc. and a const. amt. of furfural, a yellow color is obtained with benzidine. By this reagent, it is possible to det. the benzidine content of a benzidine sulfate ppt., or, after such a ppt. has been formed, the excess benzidine can be detd. in the centrifuged soln. The former, slower method is carried out as follows: To 5 cc. of soln. in a test tube, add 2 drops of bromophenol blue (0.04%) and *N* HCl until the indicator turns a pure yellow color. Add 5 cc. of water and 2 cc. of 0.025 *N* benzidine-HCl soln. and 5 cc. of 90% acetone to complete the pptn. Filter and wash 3 times with small portions of 90% acetone. Dissolve the ppt. in 15 cc. of 0.02 *N* NaOH in 50% alc. To the soln. add 10 drops of 10% BaCl_2 , make the soln. acid to phenolphthalein and add 10-15 drops of *N* HCl in excess. Make up to exactly 15 cc., mix and take 5 cc. for the colorimetric comparison. Add 2 cc. of pure 1% aq. furfural soln. and compare with solns. contg. known amts. of benzidine treated similarly. The method gave fairly good results in *urine analysis* although the presence of considerable Cl^- causes low results and H_3PO_4 causes high values. W. T. H.

Analysis of bauxite and refractories of high alumina content. G. E. F. LUNDELL AND J. I. HOFFMAN. *Bur. Standards J. Research* 1, 91-104(1928). This important paper should be read by all chemists who are likely to be called upon to make this difficult analysis. The procedures recommended are in no case novel but the critical notes are good. Two procedures are given, one for very accurate work and the other for lab. control. In the latter the Al_2O_3 , Fe_2O_3 , TiO_2 , ZrO_2 , P_2O_5 and V_2O_5 are weighed together after pptn. with NH_4OH and in another portion, all these oxides except Al_2O_3 are weighed after pptn. with cupferron so that the Al_2O_3 can be detd. by difference. In the accurate method, it is recommended to dry the powd. bauxite for 4 hrs. at 140° and then to fuse 0.5 g. with 15 times as much Na_2CO_3 . Treatment with HF, HNO_3 and H_2SO_4 is, however, satisfactory with most samples of bauxite and decompn. with $\text{K}_2\text{S}_2\text{O}_7$, with Na_2CO_3 and Na_2O_2 , or with Na_2CO_3 , Na_2O_2 and C can be made successful. Considerable emphasis is placed upon testing the SiO_2 for "mixed oxides" and the "mixed oxides" for SiO_2 . After fusion with Na_2CO_3 it is recommended to take up the melt in Pt with 150 cc. of 0.5 *N* H_2SO_4 and remove SiO_2 after each of 2 evapns. Then, after treatment with HF and H_2SO_4 , fuse the residue from the impure SiO_2 with $\text{K}_2\text{S}_2\text{O}_7$, dissolve in 3.5 *N* H_2SO_4 and add the soln. to the original filtrate from the SiO_2 . Ppt. the Al_2O_3 , Fe_2O_3 , TiO_2 , ZrO_2 , P_2O_5 , V_2O_5 and Cr_2O_3 with NH_4OH , according to the directions of Blum, wash with 2% NH_4Cl soln., dissolve the ppt. in hot 6 *N* HCl and repeat the pptn. Ignite and weigh the Al_2O_3 , Fe_2O_3 , TiO_2 , ZrO_2 , P_2O_5 , V_2O_5 and Cr_2O_3 contaminated with about 1 mg. of SiO_2 . Fuse the weighed oxides with $\text{K}_2\text{S}_2\text{O}_7$, extract the melt with 100 cc. of 3.5 *N* H_2SO_4 and recover the SiO_2 as usual. Nearly neutralize with NaOH and pour the soln. into 150 cc. 10% NaOH soln. contg. 1 g. of Na_2O_2 . Filter off the ppt., after heating an hr. on the steam bath, and reserve it for detg. Fe_2O_3 , TiO_2 and ZrO_2 . In the filtrate det. Cr colorimetrically and ppt. the Al, P and V by adding NH_4OH to the soln. which is first made acid to litmus paper. Dissolve the ppt. in 100 ml. of 3.5 *N* HNO_3 , add a little H_2O_2 and det. V colorimetrically. Then boil to destroy H_2O_2 , add concd. KMnO_4 in slight excess and decolorize with H_2SO_4 . Make acid with HNO_3 and ppt. the P as phosphomolybdate in the usual manner. Det. Al by difference. Take the ppt. reserved for the detn. of Fe, Ti and Zr, dissolve it in 25 cc. of 4 *N* HCl, add 4 g. of tartaric acid, water to make 200 cc. and neutralize with NH_4OH . Sat. with H_2S , make ammoniacal and add more H_2S . Filter off the FeS ppt., dissolve it in HCl with a little KClO_4 and det. Fe by the Zimmermann-Reinhardt method. Adjust the filtrate from the FeS ppt. so that it is 3.5 *N* with H_2SO_4 and ppt. Ti and Zr with cupferron. Wash the ppt. with 1.2 *N* HCl, dry and weigh. Fuse the ignited ppt. with $\text{K}_2\text{S}_2\text{O}_7$, take up the melt in 60 cc. of 3.6 *N* H_2SO_4 , add H_2O_2 to oxidize Ti, and 0.5 g. of $(\text{NH}_4)_2\text{HPO}_4$. After standing overnight at 40° , filter off and weigh the Zr as pyro-

phosphate. Det. Ti by difference or colorimetrically. The other detns. are made with other samples as outlined in *Bull.* 700 of the U. S. Geol. Survey. W. T. H.

Analysis of phosphorite. A. V. KRASNOVSKII. Silicates Institute, Moscow. *J. Chem. Ind. (Moscow)* 5, 408-9(1928).—Finely pulverize 10-20 g. of a representative sample of phosphorite in an agate mortar and use 3 g. of the powder for *moisture* detn. at 105-110°, and 1.5 g. for *loss on ignition*. To det. the *insol. residue* boil 5 g. with 50 cc. of aqua regia, filter and ignite the residue. Evap. the filtrate to dryness and det. dissolved SiO_2 in the usual way except using HNO_3 instead of HCl . Dil. the filtrate from the SiO_2 to a known vol. and use one aliquot portion equiv. to < 0.1 g. P_2O_5 for the P_2O_5 detn. and another portion for detg. Al_2O_3 , Fe_2O_3 , CaO and MgO . Det. P_2O_5 by the molybdc method of Woy (cf. Treadwell-Hall) but allow the yellow molybdate ppt. to stand 2-3 hrs. instead of 10 min. in a warm place and not less than 12 hrs. at room temp. before filtering. To det. $\text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$. Evap. the other aliquot nearly to dryness and treat with small, 1 g. pieces of Sn in presence of a few cc. of fuming HNO_3 over a water bath to eliminate P_2O_5 with metastannic acid. Use Blum's method for detg. Fe_2O_3 and Al_2O_3 together. Dil. the filtrate after filtering off the sesquioxides to about 300 cc., add 1-1½ cc. of 98-99% AcOH and ppt. the Ca slowly as oxalate using approx. twice as much 0.5 N $(\text{NH}_4)_2\text{C}_2\text{O}_4$ as the Ca theoretically required. Dissolve the ppt. in 2 N HCl and reppt. CaC_2O_4 . Det. Mg by the Schmitz method. The detns. of SO_3 , and of *alkalies* in phosphorite present no special difficulties but the *F* detn. deserves a special study. BERNARD NELSON

The action of hydrazine on quinquivalent arsenic in sulfuric acid solution. I. H. KUBINA AND J. PLICHTA. *Z anal. Chem.* 74, 235-47(1928).—While making some distns. of arsenate solns. with HCl and KBr , using hydrazine sulfate to reduce the arsenate to the trivalent condition, it was noticed that a grayish black deposit of As was sometimes deposited in the condenser. This led to a careful study of the reaction between hydrazine and quinquivalent As, the outcome of which showed that in moderately acid solns. the As is to a slight extent reduced to AsH_3 which is subsequently oxidized to the metallic condition. The reaction does not take place with arsenite solns. containing no arsenate nor when considerable HCl is present. W. T. H.

Behavior of vanillin toward sulfites and alkaline bisulfites. GIOVANNI ROMEO AND FRANCESCO PIRRONE. Consiglio Provinciale dell' Economia, Messina. *Ann. chim. applicata* 18, 189-93(1928).—In titrating vanillin by the general method proposed by R. and d'Amico (cf. *C. A.* 20, 561) for the titration of aldehydes, it was found that instead of a diminution of the soln., as occurred in all previous cases investigated, there was an increase of acidity corresponding to 1 equiv. per mol. of vanillin. To det. the cause of this anomaly, the behavior of vanillin with Na_2SO_3 soln. alone and with NaHSO_3 was studied. It would be predicted that with NaHSO_3 , vanillin would react, thus: $3,4\text{-MeO}(\text{HO})\text{C}_6\text{H}_3\text{CHO} + \text{NaHSO}_3 \rightarrow 3,4\text{-MeO}(\text{HO})\text{C}_6\text{H}_3\text{CH}(\text{OH})\text{SO}_3\text{Na}$ and with Na_2SO_3 would react thus: $3,4\text{-MeO}(\text{HO})\text{C}_6\text{H}_3\text{CHO} + \text{Na}_2\text{SO}_3 + \text{H}_2\text{O} \rightarrow 3,4\text{-MeO}(\text{HO})\text{C}_6\text{H}_3\text{CH}(\text{OH})\text{SO}_3\text{Na} + \text{NaOH}$, followed by $3,4\text{-MeO}(\text{HO})\text{C}_6\text{H}_3\text{CH}(\text{OH})\text{SO}_3\text{Na} + \text{NaOH} \rightarrow 3,4\text{-MeO}(\text{NaO})\text{C}_6\text{H}_3\text{CH}(\text{OH})\text{SO}_3\text{Na} + \text{H}_2\text{O}$. Therefore, with NaHSO_3 , the product should, when titrated with NaOH and rosolic acid as indicator, undergo a diminution of acidity corresponding to 1 mol. of NaHSO_3 per mol. of vanillin, while with Na_2SO_3 the product should become alk., or after the 2nd stage should be neutral. Actually in both cases, the final product becomes acid to an extent corresponding to 1 equiv. per mol. of vanillin. It is probable that at first the CHO group forms a sulfonic salt, and then the Na migrates from the sulfonic group to the OH group, with formation of an easily hydrolyzed hydrosulfone, thus: (1) with NaHSO_3 : $3,4\text{-MeO}(\text{HO})\text{C}_6\text{H}_3\text{CHO} + \text{NaHSO}_3 \rightarrow 3,4\text{-MeO}(\text{HO})\text{C}_6\text{H}_3\text{CH}(\text{OH})\text{SO}_3\text{Na} \rightarrow 3,4\text{-MeO}(\text{NaO})\text{C}_6\text{H}_3\text{CH}(\text{OH})\text{SO}_3\text{H} \rightarrow 3,4\text{-MeO}(\text{NaO})\text{C}_6\text{H}_3\text{CHO} + \text{H}_2\text{SO}_3$; and (2) with Na_2SO_3 : $3,4\text{-MeO}(\text{HO})\text{C}_6\text{H}_3\text{CHO} + \text{Na}_2\text{SO}_3 + \text{H}_2\text{O} \rightarrow 3,4\text{-MeO}(\text{HO})\text{C}_6\text{H}_3\text{CH}(\text{OH})\text{SO}_3\text{Na} + \text{NaOH} \rightarrow 3,4\text{-MeO}(\text{NaO})\text{C}_6\text{H}_3\text{CHO} + \text{NaHSO}_3 + \text{H}_2\text{O}$. C. C. DAVIS

Microanalytical determination of sulfur in organic substances by titration. BENNO-SUKE KUBOTA AND SADAHIKO HANAI. Inst. of Phys. and Chem. Research at Tokyo. *Bull. Chem. Soc. Japan* 3, 168-72(1928).—By heating in a stream of H_2 in such a way that all the vapors come in contact with Ni, prepd. by reduction of NiO in H_2 , it is possible to convert all of the S into NiS which can be analyzed for S by the iodometric method used in steel analysis, strong HCl being used to decomp. the NiS . W. T. H.

Critical comments on the analysis of glycerol by the acetin method and the sources of error. OTTO BERTH. *Chem.-Ztg.* 52, 619-20(1928); cf. *C. A.* 21, 2391.—It is pointed out that the standard method for detg. glycerol by the acetin method is likely to lead to error, particularly on account of the presence of CO_2 in the atm. In cases governing

the purchase and sale of glycerol, the chemist is obliged to make the analysis by the faulty, standard directions which should be revised. To avoid error the following method of carrying out the blank test at the time the analysis is made is recommended: Dissolve 3 g. NaOAc in freshly boiled water, add 8.5 cc. of Ac_2O and dil. to about 350 cc. Heat to about 80° to saponify the anhydride and neutralize to phenolphthalein with N NaOH. Add 50 cc. of the NaOH soln., boil 15 min., cool and titrate back with N HCl. W. T. H.

Colorimetric method for determining ethylchlorhydrin. M. B. ZAPADINSKII. *Z. anal. chem.* 74, 273-5(1928); *J. Russ. Phys.-Chem. Soc.* 60, 695-7.—Mix the sample with diazobenzenesulfonic acid and heat to 25° . This causes the oxidation of the OH group to aldehyde. Next add KOH soln., whereby a condensation of the aldehyde with diazo compd. takes place and a strong reddish coloration ensues. The color is not very stable and must be promptly compared with standards of Bordeaux-Lafitte in benzene. The results obtained agree well with those obtained by the refractometer and the method is much easier to carry out. W. T. H.

Detection of isopropyl alcohol. DOUGLAS HENVILLE. *Analyst* 53, 416-8(1928).—Isopropyl alc. can be detected by oxidizing it to acetone and then testing for the latter. In a 120 ml., narrow-necked flask, mix 10 ml. of water and 5 ml. of concd. H_2SO_4 . Cool, add 10 ml. of a 10% alc. soln. of the distillate from the original sample and thoroughly mix. Add 3 g. of powd. $\text{K}_2\text{Cr}_2\text{O}_7$, attach a small condenser, shake, allow to stand 5 min. and then distil. Use the first 2 ml. of distillate for the acetone test. Dil. this with 2 ml. of water, add 1 ml. of AcOH and 2-3 drops of a strong, freshly prepd. soln. of $\text{Na}_2\text{NOFe}(\text{CN})_6$, mixing after the addn. of each reagent. Finally, dil. with NH_4OH till the total vol. is 8 ml. A violet color will be obtained if acetone is present. It is to be noted that methylated spirits usually contain 0.5% of acetone or less. The incentive for this research was to det. the cause of some unusual cases of drunkenness in England. The trouble was laid to port wine at first but ultimately traced to MeOH. W. T. H.

The use of Mitchell's ferrous tartrate reagent in studying the precipitation of alkaloids by tannin. ARTHUR EDWARD JONES. *Analyst* 53, 421-32(1928).—A colorimetric method for detg. gallotannin has been devised by Mitchell and the accuracy of the method confirmed by Nicholson and Rhind and by Glasstone. The primary aim of the present investigation was to see whether it is possible to make use of the same reaction for the indirect detn. of alkaloids. Expts. with quinine and with cinchonine show, however, that this is not practical. The amt. of adsorption depends upon the quantity of gallotannic acid present. The colorimetric method, however, can be used to det. the extent of the adsorption. W. T. H.

Conductometric titration of the sodium salts of fatty acids with high molecular weights. PER EKWALL. *Kolloid-Z.* 45, 291-306(1928).—If NaOAc is titrated with 0.1 N HCl the cond. curve shows a steady rise but if Na laurate is titrated 3 distinct bends occur in the cond. curve. At first the cond. drops appreciably, next it rises slowly, then more rapidly and finally very abruptly. The same sort of a titration curve is obtained with Na myristate but with Na oleate the curve does not show these 3 bends but is similar to that of NaOAc. The interpretation of these phenomena is interesting. With the first 2 satd. fatty acids of high mol. wt. the initial drop in the elec. cond. is due to the fact that the original soap is decompd. and the fatty acid then combines with residual soap to form an acid soap, which, with lauric and myristic acids, is insol. These so-called acid soaps have been studied by several investigators. Apparently 1 equiv. of Na soap will unite with 0.5-2 equivs. of free lauric acid. Undoubtedly oleic acid also forms such acid soaps but the soap soln. is so colloidal and the acid soap sufficiently sol. in water to prevent the indication of its presence by conductometric titration. During the titration, as the neutral soap content drops, a still more acid soap is formed probably with 2 equivs. of free acid instead of one. This accounts for the second bend in the curve. Finally, further addn. of acid causes the decompn. of the acid soap and free lauric or myristic acid appears, thus accounting for the 3rd branch of the curve. If the titration is made in very dil. soln. a normal curve is obtained like that of NaOAc because the acid soaps are hydrolyzed and not formed in dil. solns. W. T. H.

Determination of anthraquinone in mixtures with benzanthrone. P. I. SOKOLOV AND L. GUREVICH. *J. Chem. Ind. (Moscow)* 5, 308-9(1928).—When benzanthrone is prepd. by the synthesis of Bally and Scholl (cf. *C. A.* 5, 3248) it usually contains some anthraquinone. The method of Sielisch (*C. A.* 21, 721) was tested and found inadequate for the detn. of anthraquinone in the presence of benzanthrone. Benzanthrone dissolves incompletely in the prescribed amt. of hyposulfite and it can be pptd. incompletely from the soln. by oxidizing the latter with H_2O_2 . Moreover, when much

anthraquinone is present, it is difficult to ext. anthraquinone with hyposulfite. A mixt. contg. 12.4% anthraquinone and 87.6% benzanthrone still continued to give red coloration with a 10% soln. of hyposulfite after 15 treatments with the latter soln., and an analysis showed that 25% of the anthraquinone still remained in the mixt. A new method for detg. anthraquinone is based on the oxidation of benzanthrone by chromic acid in AcOH soln. This reaction is known to destroy benzanthrone, giving anthraquinone or anthraquinone-1-carboxylic acid (Cf. Liebermann and Roka, *C. A.* 2, 2243, and Bally and Scholl, *loc. cit.*); anthraquinone, on the other hand, is known to resist the action of oxidizing agents. By effecting the oxidation of benzanthrone under such conditions that no anthraquinone is formed and only anthraquinonecarboxylic acid or other water- and alkali-sol. products, it was found possible to sep. pure anthraquinone from its mixts. with benzanthrone and thus to det. it. Dissolve 1 g. of the mixt. of benzanthrone with anthraquinone in 45 cc. glacial AcOH and heat to boiling under a reflux condenser. From a separatory funnel add a soln. of 5 g. CrO_3 , 5 cc. glacial AcOH and 5 cc. water during 2 hrs. Boil 2 hrs. longer, then dil. with 400 cc. of cold water and allow to stand for an hr. to allow the ppt. to settle. Filter and wash first with water and then with at least 150 cc. of a 1% soln. of NaOH, transfer to a 100–150 cc. conical flask and treat at 70° with 15 cc. of a 10% soln. of $\text{Na}_2\text{S}_2\text{O}_4$ in 10% NaOH. Filter the red soln. of anthraquinone thus obtained through a Gooch crucible, wash the residue with a 1% soln. of hyposulfite and add to the filtrate at 70°, 5 cc. of 30% H_2O_2 . Filter off the anthraquinone ppt., using a weighed filter, wash with water, dry and weigh. If the sample to be analyzed is known to contain more than 50–60% of anthraquinone, the treatment with hyposulfite may be omitted. In such a case wash the ppt. obtained after oxidation, first with water, then with alkali, then with water again and finally dry and weigh.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIRER

Relation between hardness and coefficient of expansion of minerals. M. I. LIPOVSKII. *Ann. Inst. Polytech. Oural* 5, 123–8 (1926).—Data are discussed showing that the hardness of minerals diminishes with increasing coeff. of expansion. A rational scale of hardness is suggested, based on exact measurements of coeffs. of expansion. B. C. A.

Some applications of the "zinc" test for cassiterite. G. H. STANLEY. *J. Chem. Met. Mining Soc. S. Africa* 28, 249–51 (1928).—Two applications for the identification of cassiterite are outlined. One applies the method to the examn. of rock sections or polished faces. The polished surface is spread evenly to a thickness of $\frac{1}{8}$ in. with a water paste of Zn dust, a thick soft filter is laid upon it and then inverted into a flat-bottomed dish into which dil. HCl (1:1) is poured. Action is allowed to proceed about 15 min. and the piece is washed and dried. It exhibits a characteristic gray color and dull metallic appearance. A second application is in ore concn., and particularly concn. tests. If a mixt. is placed upon a Zn sheet or in a hole drilled in a Zn block and HCl mixed with it, the cassiterite becomes Sn-coated. After washing, microscopic examn. shows the particles of cassiterite clearly visible and the amt. may be estd. W. H. B.

New investigations on the transformations of scolecite. A. CAVINATO. Univ. Padova. *Atti accad. Lincei* [6], 7, 670–2 (1928).—In earlier expts. in which it was shown that scolecite undergoes successive dehydrations at 160–200° and at 335–45° (cf. C. A.

22, 1559), it was not ascertained whether the optical changes occur simultaneously with the dehydration or at merely approx. the same temps. Further tests with better crystals showed that the 2 phenomena occur at the same temps. and that they are causally related in that the changes in the optical properties result from the dehydration or rehydration of the scolecite. C. C. DAVIS

The potash deposit of Sebkhah el Melah, Tunis. P. BOVIS. *Chimie et industrie* 19, 937-44(1928).—A brief description of the deposit with a discussion of the possible methods of working it which were tried out during the war. One of the big advantages of the working of this deposit over the extn. of K from sea water is that the compn. of the Sebkhah waters is such that on evapn. they deposit a more or less impure carnallite, whereas the product obtained from sea water approximates more nearly to kainite. A. PAPINEAU-COUTURE

The conditions and geological evidence of base exchange between the roofs of bituminous coal seams and solutions of sodium chloride. E. MCKENZIE TAYLOR. School of Agriculture, Cambridge, Eng. *Fuel in Science & Practice* 7, 130-4(1928); cf. C. A. 22, 2907.—The characteristic of a roof formed under marine conditions is that it has undergone base exchange. The characteristic constituent of the roof would be a Na-Al-SiO₂ complex in case drifted material accumulated in the sea or in fresh water, if in the latter case submergence in the sea could take place. If accumulated material was covered by a roof deposited in fresh water, a slight alteration in land level could result in base exchange with capillary solns. of NaCl raised from subsoil. It follows that although the modes of accumulation of the plant residues may have been widely different, the final roof conditions detg. the type of decompn. has been similar in all cases. The roof is the main factor concerned in the formation of bituminous coal, the mode of accumulation having much less bearing on coal type. D. A. REYNOLDS

Native asphalts in Oregon. EDWIN T. HODGE. *Bull. Am. Assoc. Petroleum Geol.* 11, No. 4(1927).—The native asphalts in Oregon have never been thoroughly described, their character has not been detd. or their significance discussed. H. presents a complete list of all known occurrences, some of recent discovery, and tenders for the first time analyses and detns. of their character. They are found to be mixts. of uinitahite, manjak and wurtzilite, or pure uinitahites and grahamites. These native asphalts have been derived probably from deep-seated Cretaceous rocks, which once possessed reservoirs of petroleum. The petroleum was brought to the surface by dynamic movements and their method of emplacement shows no influence of thermal metamorphism. Some of the Oregon occurrences are similar to those found in other localities which have since developed into important oil fields. Others are unique, and neither in Oregon nor elsewhere have they heretofore been described. The discussion has an important bearing on the possibilities of petroleum in Oregon. C. L. COOPER

The present status of the carbon-ratio theory. GEORGE E. DORSEY. *Bull. Am. Assoc. Petroleum Geol.* 11, No. 5(1927).—Many geologists are of the opinion that the observations of White, Fuller, Russell, Moulton and other investigators constitute proof of a causal assumption in pointing out that there is a definite relationship between degrees of alteration, using the fixed C of coal as a pyrometer, and oil and gas occurrences. Others, although not questioning the observational data indicating the relationship, are led by the serious inconsistencies in the application of the theory, to believe no causal connection has been proved. The chief inconsistencies are: (1) the problem of residues, (2) the occurrences of oil of lower grade in older beds below higher grade oil in younger beds, and (3) the presence of areas producing only dry gas in quantity in the same zone of alteration with areas producing oil, or oil and gas. D. seeks in this discussion to compare the evidence regarded as proof of the theory with these inconsistencies. The conclusion is reached that, so far as the causal part of the theory is concerned, it is still an unproved assumption. C. L. COOPER

The proofs of the carbon-ratio theory. WM. L. RUSSELL. *Bull. Am. Assoc. Petroleum Geol.* 11, No. 9(1927).—R. does not cite evidence of the relation between isocarbs and oil and gas occurrence, but presents available data indicating that this relationship is produced by tectonic forces more than by conditions of sedimentation, concluding that the exptl. data regarding the generation of oil and gas from bituminous rocks are at present too meager to furnish any definite evidence regarding the validity of the C-ratio theory; that the field evidence indicates that the porosity of sandstones and other reservoir rocks is reduced by dynamic alteration and that this decrease in pore space is an important factor in causing the absence of oil in areas containing coals of high C ratios; that the intense deformation of rocks causes the oil and gas to escape, and that this is one reason why they are absent from areas that have been acted upon by great tectonic forces; that the tendency for gas rather than oil to occur in areas of

greater alteration is probably due chiefly to the lower porosity of these rocks and the action of dynamic pressures on the source material, though the variations in the conditions of sedimentation may have been operative also; and that the distribution of marine bituminous strata in the 3 geosynclines that may be used to test the carbon-ratio theory shows that dynamic alteration and not the conditions of sedimentation is chiefly responsible for the barrenness of the areas in which the C ratios of the coals are high.

C. L. COOPER

The carbon-ratio theory in the light of Hilt's law. FRANK REEVES. *Bull. Am. Assoc. Petroleum Geol.* 12, No. 8(1928).—The principal tenets of the C ratio theory are (1) that the chief agencies in the chem. transformation of carbonaceous deposits, after they have passed through the biochem. stage are the pressure and the heat derived from the horizontal thrust; (2) that as the coals decrease in volatile constituents the oils show a corresponding increase in the lighter and more volatile hydrocarbons, so that low-grade oils are assocd. with low-rank coals and high-grade oils with high-rank coals; and (3) that where the coals have reached the stage of devolatilization at which their content of fixed C constitutes about 65% of their total combustible matter the oils in the coal-bearing and underlying formations have been converted into gases, and where the state of devolatilization is slightly higher the gases have been eliminated. Inasmuch as a series of coals increases in fixed C with stratigraphic depth in both disturbed and undisturbed areas, and this increase is many times greater than any recorded increase in the horizontal direction, R. concludes (1) that the geologic agencies producing the chem. transformation of carbonaceous deposits are not so much the heat and pressure incident to horizontal thrust as the heat and pressure incident to depth of burial; and (2) that there is no clear evidence that incipient alteration of sediments has been a factor in detg. the extent of our known oil and gas fields and therefore that C ratios of coals furnish no information as to the oil possibilities of an area. C. L. C.

Generation of oil by geologic distillation during mountain-building. JOHN L. RICH. *Bull. Am. Assoc. Petroleum Geol.* 11, No. 10(1927).—In regions of intense mountain-folding carbonaceous shales have lost the oil which, presumably, they once contained in the form of "kerogen" or similar mother-substance, and which is still present in equivalent rocks outside the metamorphosed zone. The newer information on mountain-building indicates that folding commonly took place at considerable depth underneath great overthrust sheets of rock. Under such conditions it is believed that the oil was distd. from the carbonaceous rocks in what was, virtually, a giant high-pressure cracking still, and that it found easiest escape laterally along the bedding, being driven out to cooler zones by the gases generated during the distn. In later geologic ages the overthrust sheets became worn away and the whole area broadly uplifted, bringing the rocks formerly subjected to distn. up to the surface and opening their porous beds to the inflow and artesian circulation of meteoric waters which caused extensive secondary migration of the oil. In the zone of intense metamorphism no oil would remain, the carbonaceous rocks would be devolatilized and C ratios would be high. In an intermediate zone where the rocks are partly devolatilized, some of the oil would have been distd. in place, and some would have migrated from adjacent zones of more intense metamorphism. In a broad belt outside the zone of active distn. such oil as found would not have been formed *in situ*, but would have migrated from adjacent zones of distn. under the influence of gas pressure and artesian circulation. C. L. COOPER

Results of distillation and other studies of the organic nature of some modern sediments. PARKER D. TRASK. *Bull. Am. Assoc. Petroleum Geol.* 11, No. 11(1927).—A report of the first year's work on the Am. Petroleum Institute's research project on the "origin and environment of possible source beds of petroleum." In order to obtain a measure of the org. content of recent deposits from a no. of different types of environments, so that some one area may be found where possible "source beds" are actually accumulating today, the dried sediment is distd. in the same manner that the oil shales are assayed. Of the 45 samples that have been distd. to date, all types of sediment, ranging from sand to clay, yielded small amts. of oil. Recent deposits extd. with org. solvents gave but very small yields. Analyses of several different recent sediments show that the org. content in general varies directly with the fineness of grain, being low in sands and high in clays. Material from the bottom of depressions in the sea floor of the Pacific Ocean west of Los Angeles and the Gulf of Maine seems to be richer in org. content than the adjacent shallower regions. C. L. COOPER

Westbrook Field, Mitchell County, Texas. F. C. EDWARDS. *Bull. Am. Assoc. Petroleum Geol.* 11, No. 5(1927).—The productive reservoir is dolomitic limestone. The oil has a sp. gr. 28.8° Bé, and contains 4% S and 32% gasoline. Its source is probably the Permian limestones and shales. Two kinds of gas occur in the field: (1) non-in-

flammable gas at depths between 1000 and 1300 feet, and (2) wet petroleum gas in both oil zones.

C. L. COOPER

Outline of water problems in new Grozny Oil Field, Russia. NORBERT T. LINDTROP. *Bull. Am. Assoc. Petroleum Geol.* 11, No. 10(1927).—The Grozny district contains 3 oil fields: the old and new Grozny and the Vosnesenskaja fields. There were 450 producing wells in 1926. Fifteen of these flowed by hydrostatic pressure, and yielded half of the total daily production. Twenty-two Miocene sands are encountered in drilling. Eight of these are oil sands. Water conditions have been given special study because of the several oil sands and intermediate water sands in the same well. Several sizes of casing are required to shut off the waters above each producing sand. In distinguishing the several waters and thus in correlating the sands, the characteristics of the waters were calcd. after the method of Palmer in reacting values and chemical properties. Tables and charts are given, showing these comparative properties. L. concludes that edge water is encroaching and the future production should be small.

C. L. COOPER

The Crinerville Oil Field, Oklahoma. SIDNEY POWERS. *Bull. Am. Assoc. Petroleum Geol.* 11, No. 10(1927).—Analyses of Ordovician water, Crinerville Field are:

Constituent	Marris No. 2, SE. cor. Sec. 20 g. per l.	S. Baptiste No. 4 NE. SE. Sec. 20 g. per l.
Calcium chloride	25.380	23.510
Sodium chloride	89.700	85.150
Magnesium chloride	11.818	11.690
Fe and Al oxides	0.110	0.120
Silicic acid	0.050	0.090

C. L. COOPER

Connection between commercial oil deposits and major structural features with special reference to Asiatic fields. L. DUDLEY STAMP. *J. Inst. Petrol. Tech.* 14, 28-63 (1928).—A critical examn. of the occurrence of oil fields shows their frequent assoc. with geosynclinal areas of deposition and occurrence around the margins where the deposits are of a deep-water type, or in the center in the case of shallow-water deposits. No genetic connection between oil and belts of folding or between oil and vulcanicity can be traced.

B. C. A.

The lava of Etna. W. F. GISOLF. *Verslag. Akad. Wetenschappen Amsterdam* 37, 459-68(1928).—The method outlined in *C. A.* 22, 1122 was used for petrographic study of the lava.

A. L. HENNE

An interesting lava-flow at Petronella in Agro Romano. ENRICO CLERICI. *Atti accad. Lincei* [6], 7, 769-72(1928).—The mineralogy is described in detail. Feldspar, pyroxene, plagioclase, augite, FeS and S are present in the vitreous base. Analyses of the lava gave: SiO₂ 52.01, Fe₂O₃ 4.26, Al₂O₃ 17.66, CaO 6.81, MgO 2.71, loss at 110° 3.86, loss on ignition 10.16%.

C. C. DAVIS

Chemical and provincial relations of the younger eruptive rocks of Germany and northern Bohemia. H. JUNG. *Chem. Erde* 3, 137-340(1927).—A large no. of chem. analyses of Tertiary igneous rocks from Germany and northern Bohemia, collected from the literature, are tabulated and plotted on diagrams. Variation curves are given for each of the constituent oxides. The rocks of the "Oligocene province" are all alkali-rocks of the "Atlantic type," while in the "Miocene province" there are also lime-alkali-rocks of the "Pacific type."

B. C. A.

Altered volcanic materials and their recognition. CLARENCE S. ROSS. *Bull. Am. Assoc. Petroleum Geol.* 12, No. 2(1928).—The relict glass structure, the nature and habit of crystal grains, and the phys. properties present evidence that indicate the mode of origin. Bentonite is a common type of altered volcanic material and may be recognized by the volcanic structure preserved in the clay substance, and the origin is confirmed by the presence of volcanic minerals. The chem. and phys. properties of bentonite are variable and many are indefinite; thus, although they may contribute to its recognition, as a rule they cannot be relied upon completely. Bentonites from several eastern States, Nova Scotia, Ark., Texas and N. M. are described in detail. It is concluded that volcanic materials, even though highly altered, may be recognized by microscopic and phys. studies and may contribute to the interpretation of the geologic history of a region.

C. L. COOPER

Subsurface correlation by means of heavy minerals. R. D. REED AND J. P. BAILEY. *Bull. Am. Assoc. Petroleum Geol.* 11, No. 4(1927).—This paper describes the attempt to make practical use of heavy mineral zones as a means of detg. structure

in a part of the San Joaquin Valley where other means were not available. It presents a part of the data, along with a discussion of their bearing on some of the general principles involved. The conclusion is reached that the method is likely to be of considerable use if applied with due regard to certain limitations. C. L. COOPER

Genesis of a sandstone dike as indicated by heavy minerals. CHARLES E. MEEK. *Bull. Am. Assocn. Petroleum Geol.* 12, No. 3(1928).—Heavy mineral analyses show that the material of the dike corresponds with the underlying Miocene sand rather than with overlying younger formations. The Miocene in the area is characterized by a lack of green hornblende and an exceptionally large amount of glaucophane. The reverse is true of the Pleistocene. An earthquake probably formed a fracture into which was forced water-soaked sand from a lower formation. The oil and tar which occur in the dike and the overlying Pleistocene beds probably entered subsequently to the sand-filling of the dike. C. L. COOPER

Loss of color of red sandstone upon deposition. LON D. CARTWRIGHT, JR. *Bull. Am. Assocn. Petroleum Geol.* 12, No. 1(1928).—Fragments of a red sandstone (Sespe formation) have been carried by the streams from the mountains to the beach between Los Angeles and Santa Barbara, Cal. The change of color from red to rusty brown, yellowish buff, light green or greenish gray and grayish buff is believed to be due to the action of C compds. and natural org. acids formed from the vital processes and decay of plant and animal organisms found along the beach. The red color of the Sespe sandstone was found to be due to a Fe_2O_3 stain on the grains and matrix. The continued wetting of the sandstones without thorough drying would hydrate this from the red hematitic state to the brown limonitic state. The reducing action of the org. solns. in the sea water would reduce the brown Fe_2O_3 to the greenish ferrous state. CO_2 solns. would then leach away the ferrous salts and leave unstained mineral constituents, the aggregate color of which varies from a light gray to grayish buff, depending upon the relative abundance of biotite. C. L. COOPER

Occurrence and determination of metals of the platinum series in Norwegian rocks. II. GULBRAND LUNDE AND MIMI JOHNSON. Oslo Univ. *Z. anorg. allgem. Chem.* 172, 167-95(1928).—The first of the paper is an extensive survey of the sepn. and detn. methods (cf. *C. A.* 21, 2636). The second part records the noble metals contents of various Norwegian rocks. A. L. HENNE

Chemical x-ray spectrography (THOMASSEN) 7.

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, R. H. ABORN

Why flotation has displaced cyanidation at Cortez. J. O. GREENAN AND E. M. BAGLEY. *Eng. Mining J.* 126, 173-6(1928).—The encountering of new harder ore bodies contg. a much larger proportion of sulfide minerals reduced the grinding capacity of the mill, reduced the extn. of Ag to 65%, and increased cyanide consumption to a prohibitive extent. The milling cost reached a max. of \$4.26 a ton. A 200-ton flotation unit was installed consisting of 4 Parker cells, 3 roughing cells and 1 cleaner cell. The result was based on a low cyanide tonnage was a greater output, an increase of 12.6% in Ag recovery, decreased milling costs and a total decrease of \$1.84 a ton in total cost including refining. In short, flotation is responsible for the continuance of profitable operations at Cortez and increased efficiency and economy as anticipated. H. C. PARISH

Metallurgical applications of silicon and beryllium. ANON. *Metallurgist* (Suppl. to *Engineer* 146, No. 4) 106-7(1928).—Si is used as electrodes in wet or dry electrolytic rectifiers. As ferro-Si it is a satisfactory reducing agent in manuf. of Cr alloys. *Everdur*, contg. 95% Cu, 4% Si, 1% Mn, withstands corrosion even by HCl. Al-Be alloys have a tensile strength increasing from 9500 to 23,000 lb. per sq. in. as Be is increased up to 20%. At the same time elongation increases from 22.5 to 39%. D. B. DILL

From copper ore to heavy current cable. CONSTANTIN REDZICH. *Apparatebau* 40, 181-7(1928).—An outline of the metallurgy of Cu and the manuf. of elec. cables, with 17 cuts. J. H. MOORE

PARISH

The Penpoll tin smelter at Bootle. ANON. *Engineer* **146**, 74(1928).—The capacity of this new smelter is 1000 tons of ore per month with an output of 650 to 700 tons of 99.95% Sn. D. B. DILL.

Preliminary investigation of tailings for retreatment. I. L. BOX AND E. H. CRABTREE. *Mining & Met.* **9**, 316-7(1928).—Before planning retreatment or designing a plant to handle Zn tailings a thorough investigation of the tailings is essential. In general this consists of a careful survey of the tailing pile to det. its tonnage, the taking of a no. of samples by means of an auger with casing, analysis, screening and flotation tests of the samples. Various cuts of a 27-lb. sample varied in ZnS content from 0.67 to 1.19%. Figures are given showing the ZnS content of various sizes and in the "sink" and "float" for tailings in question. H. C. PARISH.

The extraction and application of thorium. G. MALCOLM DYSON. *Chem. Age (London)* **19**, Metallurgical Section, No. 471, 2-3, No. 475, 10-11(1928). E. H.

Recent developments in the application of nitrogen to the surface hardening of steel. V. O. HOMERBERG. *Fuels and Furnaces* **6**, 1153-7(1928). E. H.

Cupola fired with powdered coal. FRITZ MEYER. *Iron Age* **121**, 1593-5(1928).—M. describes a cupola fired with powd. coal now in operation at the American Radiator Co., Springfield, Ill. In the cupola the powd. coal is burned under pressure outside the shell proper, allowing the products of combustion to pass directly to the smelting zone at a velocity insuring penetration. A min. charge of coke is used. In this manner it is possible (1) to decrease by 20% the amt. of S picked up, (2) to control the C in the mixt. because there is more accurate control of combustion, (3) to obtain higher strength because of super heat, (4) to cut the smelting cost from \$1.35 per ton of metal to \$0.67 per ton, (5) to decrease the price of various mixts. A. W. C.

Powdered coal in steel furnaces. E. L. HERNDON. *Iron Age* **121**, 1603-4(1928).—Four to fifty ton steel furnaces and 2-80 ton furnaces fired with powd. coal are described. These furnaces have been in operation in the plant of the Eastern Steel Co., Pottsville, Pa., for 13 years. A. W. C.

Metallographic structural relationships. H. J. SEEMAN. *Z. tech. Physik* **9**, 233-40(1928).—A review of recent work on lattice theories and related properties of metals and alloys (cf. Westgren and Phragmen, *C. A.* **20**, 2654, Zsigmondy, *Kolloid-Z. Fest-schrift* **2**, 36(1925)). Fifty references are given. B. J. C. VAN DER HOEVEN.

Methods for the thermal and microscopic investigation of alloys of reactive metals. WILLIAM HUME-ROTHERY. Oxford Univ., Eng. *J. Inst. Metals* (advance copy), No. **478**, 16 pp.(1928).—Some reactive metals such as Mg can be melted for thermal analysis in a small crucible placed inside a vertical quartz or Fe tube extending upward out of the furnace and plugged loosely at the top. Other more reactive metals must be fused in a completely closed tube with asbestos screens to protect the plugged end from the heat of the fusion. Melting *in vacuo* often causes too much volatilization, and fluxes attack the refractories, the use of an atm. of argon is suggested instead of H₂ or N₂, and pressure can be used with volatile metals. Alundum or alundum-lined crucibles and thermocouple sheaths are recommended. The difficulty of obtaining the exact compn. of a reactive alloy, at the time when a thermal analysis was made, is described and pouring off a small sample from the melt for analysis is recommended, just before taking a cooling curve. For investigation of changes in solid reactive alloys, chill castings are best made in Cu molds, which if necessary can be placed inside the closed melting-tube for casting without access to air. For microscopic examn. specimens may be mounted in fusible alloy, polished and examd. under oil if necessary. A sketch shows an app. for conducting the examn. in an inert atm. The method of detg. the compn. of a phase from the duration of thermal arrests is shown to be inaccurate except in the case of simple eutectic arrests where no solid solns. are found. The detn. of the temp. of changes where super-cooling or suspended transformation is shown should be based not only on heating and cooling curves, but on changes of elec. cond. or of micro-structure with rising temp. G. F. C.

Work softening of eutectic alloys. F. HARGREAVES AND R. J. HILLS. Southern Railway, Ashford, Eng. *J. Inst. Metals* (advance copy), No. **474**, 14 pp.(1928).—Previous work on eutectics was chiefly morphological. Pb-Sn alloys were etched with strong HCl to show the Sn crystal boundaries, and with a 5% soln. of FeCl₃ for differential staining. The microstructures and Brinell hardness were studied. Straining of the Pb-Sn eutectic caused twinning of the Sn, and reduced the etching contrast. A coarser-grained eutectic recrystallized more quickly after working and pure Sn very quickly at room temp. The original eutectic structure was most easily obliterated by about 30% reduction by cold work. Small grains are formed much faster by annealing at higher temp. The presence of Pb in Sn decreased greatly the ease of recrystn. and the soften-

ing by cold-work. The reduction in hardness of various Pb-Sn alloys by cold-working is shown by curves. The eutectic showed a sudden decrease in hardness at 30% reduction. This is a crit. amt. of work for these alloys, similarly to the case of single Al crystals. Work-softening is due to interphase movement and the retention of the two constituents in the disturbed mobile condition. The work-softening of the Cd-Zn eutectic was found to be of the same nature and not due to a phase change in the Cd, and all hot-forged alloys of two or more phases are probably similarly affected.

G. F. C.

Thermal brittleness in metals. TAKEHIDE INOKUTY. *Science Repts. Tôhoku Imp. Univ.* 17, No. 4, 817-42(1928).—Blue brittleness of Fe is not accompanied by any change in magnetic, elec. or thermal properties. Tempering a cold-worked metal at a low temp. may release only an unstable strain, the metal becoming more stable and hence slightly harder. The hardening effect of very slow deformation at room temp. may be obtained faster at a higher temp., but the temp. must not be so high as to cause annealing. For hardening by shock, a higher temp. (600°) is required. This effect was investigated in 7 metals or alloys by tensile and hardness tests at various temps. between -190° and 200°. The app. and methods are described in detail. Thermal brittleness, evidenced by a slight upward irregularity in the strength-temp. curve with corresponding lower ductility, was found at the following temps. for the metals noted: Fe about 250°; Al, -100° to 200°; Sn, -100° to 30°; Zn, doubtful around 120°; Cu, -20° to 500°; Pb, -130° to 40°; brass, -100° to 550°. The speed of testing was 11 mm. per min.; at other speeds different temp. ranges may be found.

G. F. C.

Failure of metals under tensile stress. K. YUASA. *Proc. Imp. Acad. (Japan)* 3, 603-6(1927).—An app. is described for testing metals under tensile stress which is free from inertia effect and in which the applied load is self-adjusting. A medium-hard steel (0.65% C) was tested at temps. of 139°, 171°, 198°, 295°, 358° and a record obtained optically which is a load-time curve of the test piece: as the load is applied with uniform velocity, the curve is a tensile load-elongation diagram. At certain temps. the diagrams show irregular jumps after the yield point is passed. At each discontinuity the resistance of the metal decreases suddenly and then increases uniformly until another discontinuity is reached. The no. of occurrences and the intensity of these irregularities increase with the rise of temp. and reach a max. at about 250°; this temp. nearly corresponds to that of "blue brittleness." With a further rise of temp. this irregularity decreases and finally, at about 350°, disappears. Under such a temp. the nature of deformation of the test piece would be that due to viscous flow. In the course of irregular deformation a cracking sound is heard which occurs whenever the stress makes a sudden change.

C. J. WEST

The limit of elongation of steel in tension. W. KUNTZE AND G. SACHS. Kaiser Wilhelm Inst. für Metallforschung, Berlin-Dahlem. *Z. Ver. deut. Ing.* 72, 1011-6 (1928).—Extensive studies upon the deformation of steel (especially high-grade Si-steel) are reported. On a no. of tests the changes in cross-section over the whole length of the test pieces were followed out. The first strongly marked deformations occurred usually with a diminution of load and the constriction of a certain place on the test rod. Then the narrow portion extended until the rod again became cylindrical throughout its entire length, the load meanwhile remaining approx. const. Further deformation then occurred (as with other kinds of materials) with a regular increase in length and accompanying load. The first change noted is due to a break in the brittle components, especially as it always occurred on the head of the test piece or near an injured place, while the final break occurred as a rule in the middle of the test piece or around the weakest part of the rod. The phenomena are not to be looked upon as a simple mech. process, taking place in a compound body made up of iron in a hard cementite skeleton. "Aging" at low temps. induces a considerable improvement in the stretched portions of the rod, new deformations arising there accompanied by diminutions in load. They are to be looked upon as properties accompanying transformations. Corresponding to the properties of a brittle body, the load under which the first failure occurs is dependent upon the formation of the head of the test piece.

W. C. EBAUGH

Universal machine for testing the hardness of castings, the static flexion and the shearing stress, and a machine for testing sheet metal for stamping and rolling. R. GUILLERY. *Bull. soc. encour. ind. nat.* 1928, 438-502.—A detailed description of the app.

T. S. CARSWELL

Tensile test of steels at high temperatures. TAKEHIDE INOKUTY. *Science Repts. Tôhoku Imp. Univ.* 17, No. 4, 791-816(1928).—Tensile tests were made of specimens of forged and annealed steels contg. up to 1.5% C at temps. up to 1100°. Temp. differences in the specimens under test were not over 14°; the observed temp. at the outer

surface of a specimen was cor. by an amt. up to 40°, derived from measurements on a hollow dummy specimen with a thermocouple inside, so as to give the probable internal temp. The heating furnace was arranged so that its center followed the center of the specimen during testing. The results, plotted as curves, show for the tensile strength of all steels a min. at 100°, a max. between 200° and 300°, and in steels contg. less than 0.7% C another max. between 800° and 930°. The elongation and contraction of low-C steels varied about inversely with the strength. Hypereutectoid steels were no stronger than eutectoid steels, and less ductile, at all temps. Above 800° steel contg. 0.3% C was more ductile than other steels. The elongation occurring up to the time of max. load, or "general elongation" was greatest at room temp., and the chief elongation occurring at high temp. was local and generally related to the contraction. The elongation is a better measure of ductility than the contraction. The effect of structure on the tensile properties is discussed; the A_3 transformation produces a sudden change in strength and ductility and is most prominent in very low-C steels, which should not be worked at around 900°. Results of other investigators are noted briefly.

G. F. C.

Heat treatment of ferrous metals. C. M. WALTER. *J. Soc. Chem. Ind.* 74, 791-7T(1928).—Theoretical consideration is given to the application of heat to steel and other ferrous materials, together with a description of the shop operation and furnaces for annealing, hardening, tempering, normalizing and carburizing. D. S.

The influence of different conditions of iron on its chemical behavior. OSKAR BAUDISCH. Rockefeller Inst., N. Y. *Naturwissenschaften* 16, 542-5(1928).—The reductive action of freshly pptd. $\text{Fe}(\text{OH})_3$ on nitrate in the presence of air (essential for the reduction) is discussed with a review of a series of papers by B. and co-workers. (Cf. *C. A.* 21, 1914.)

B. J. C. VAN DER HOEVEN

Diffusion phenomena of zinc and tin in steel and soft iron. H. HONIGL. *Mikrochem.* 6, 22-7(1928).—Sn begins to diffuse into Fe and steel at 300° with the formation of a thin layer of solid soln. which at this temp. appears to hinder further diffusion. At 500-750°, however, diffusion of Sn into steel proceeds rapidly with the formation of several layers of intermetallic compds. interspersed with crystals of solid solns.; at the same time the C content of the steel diffuses towards the central portions, leaving a layer of decarburized steel inside the layers of Sn-Fe compds. At 900° there is a pronounced tendency for the C to diffuse back toward the edges of the test-piece. The rate of diffusion of Zn into Fe increases rapidly with the temp. above 500° with the formation of 3 distinct layers of differently oriented mixed crystals, accompanied by an enrichment of the C content of the inside portions of the test-piece. B. C. A.

Influence of occluded oxygen in steel upon the carburizing quality of steel. KATSUMI INOUE. Sorbonne, Paris; Kyushu Imp. Univ., Fukuoka, Japan. *Mem. Coll. Eng.* 5, No. 1, 69 pp., 7 plates(1928).—Several specimens of steel in different states of manuf. and specially prepd. samples were first analyzed and their O content was detd. by means of Oberhofer's method. It was found necessary to use the finest grade of drillings (less than 0.5 mg.) and to pass a rapid stream of H_2 (at least 100 cc./min.) for 2 hrs. at 1200° over 5 g. of the sample mixed with about 10 g. of a 60/40 Sn-Sb alloy. With high C-steels there is a possibility of CO or CO_2 being evolved. The percentages found ranged from 0.042 to 0.232% O. The oxides present appear on highly polished surfaces at high magnification as minute grayish black specks. When the O content is high the oxide globules show a duplex structure. The effect of occluded O on the grain size, critical points, sp. resistance and carburizing qualities of various samples of known O content was then studied. The grain size and sp. resistance increase with increase in O content. The critical points are not noticeably affected by the O content. A marked difference was found in the microscopic structure of carburized steels of different O content. The difference is most pronounced in the hypereutectoid zone. In carburized steel with 0.165% O (and more) I. found a curious abnormal structure consisting of granular pearlite, free, disintegrated (coalesced) cementite and "free ferritic substance" (possibly composed of Fe, C and O but usually called ferrite). Fast cooling has the tendency to hinder the formation of abnormal structures. Annealing before carburization has little or no effect on the structure of the carburized zone. It may bring about partial coagulation of the oxide particles distributed in the steel. Mech. treatments (forging for instance) have likewise no effect on the structure. Steel samples deoxidized with ferro-Si or ferro-Mn showed after carburization a comparatively normal structure while a specimen deoxidized by Al became abnormal after carburization. This is possibly due to the fact that the Al_2O_3 particles do not fuse nor coalesce readily. The depth of penetration of C is slightly higher in large-grained samples of higher O content than in those with lower O content.

H. S. VAN KLOOSTER

The mechanism of carbon penetration in the cementation of iron and steel. GENSKE TAKAHASHI. *Science Repts. Tôhoku Imp. Univ.* 17, No. 4, 761-82 (1928).—A review of previous literature is given describing the two prevailing theories of carburization, namely, that the C penetrates as a gaseous compd., or by diffusion as elemental C. An app. is described in detail for carburizing the outside of an Fe or steel tube evacuated inside. When a regular carburizing mixt. was used, H_2 penetrated into the interior of the tube, but when CO or other gas was used, no rapid increase in pressure occurred inside the tube when evacuation ceased. The amt. of C absorbed by the tube during carburization is shown to be much larger than is consistent with the possibility of diffusion and decompn. of CO and consequent expulsion of CO_2 to the interior of the tube in amts. indicated by the pressure readings, or with the known slowness of movement of CO or CO_2 in steel. The conclusion is that the CO decomposes at the surface of the steel or Fe, and the carburizing occurs by diffusion of nascent C atoms. This is considered the mechanism of carburization also when hydrocarbons or cyanogen are used.

G. F. C.

Die-casting of copper-rich alloys. R. GENDERS, R. C. READER AND V. T. S. FOSTER. *J. Inst. Metals* (advance copy), No. 475, 32 pp. (1928).—Most bronze die-castings made in England are composed of the 90-10 Cu-Al alloy, with up to 3% Fe. Molds are of cast Fe, with steel inserts and cores, which are dipped into a plumbago wash after each casting. The casting temp. is 1150° to 1300° , and the mold temp. 200° to 300° . Most castings of uneven section are locally unsound, and those made of brass are more defective. Chill-cast test-bars of Al-bronzes contg. Fe, Ni, Mn, etc., and of brasses contg. Fe, Ni, Al, etc., were prepd. and tested in tension, the hardness and d. also being detd. The tabulated results show an extensive range of properties. Expts. with a particular shape of die-casting showed that the gate should be placed on the thickest part for max. soundness. High-tensile brass was used with success, giving strengths around 40 tons per sq. in., but required sometimes a larger runner because it was less fluid than Al-bronze. The addn. of 4% Fe to Al-bronze raised the proof stress and strength; addn. of 10% Ni raised the proof stress still more, but decreased the ductility greatly. Pb in Al-bronze made it weaker, easier to machine, and more liable to show surface defects. The properties of chill-cast brasses contg. not over 71% Cu and up to 8% Al were investigated in detail, and are tabulated, showing that the addn. of Al up to 4% increased the proof stress and tensile strength while maintaining a good ductility. This alloy with 60 to 70% Cu had tensile properties similar to those of Al-bronze, and gave good die castings when poured at 1050° to 1100° . The fatigue limit was 7 to 10 tons per sq. in., while that of Al-bronze was 13, and that of brass without Al, about 4 tons per sq. in. The color was reddish and the resistance to corrosion as good as that of Al bronze. The structures found in some of the ternary Cu-Zn-Al alloys are indicated by diagrams. The equivalence value of Al for Zn is not a const. for different alloys. Alloys contg. γ phase have inferior properties and should be avoided. Core materials were investigated by immersion in Al-bronze at 1100° and in 60-40 brass at 1000° . The attack was increased when the molten alloy was in motion and was less on high-C steel or cast Fe than on pure Fe. Alloy steels were attacked badly, except special heat-resisting alloys high in Cr. To avoid deterioration by partial fusion, cast Fe should not contain over 0.3% P. Cr plating gave perfect protection if it was continuous and adherent. Brass attacked all materials much less than Al-bronze did. Calorizing of the molds gave good protection. Brasses contg. Al are very promising as materials for die-castings, as they are cheaper, have a higher proof stress, and attack the molds less than Al-bronze.

G. F. C.

The alpha-phase boundary of the copper-silicon system. CYRIL STANLEY SMITH. Am. Brass Co., Waterbury, Conn. *J. Inst. Metals* (advance copy), No. 476, 12 pp. (1928).—The results of Rudolphi, Sanfourche and Corson on the Cu-Si system are briefly reviewed. Alloys contg. up to 8% Si and less than 0.06% impurities were melted in graphite for thermal analyses, the method, which gave sharp arrests, being described in detail. The peritectic horizontal at the top of the β field was found at 852° . At 782° a sharp and const. arrest was found and it was thought to be eutectoidal rather than an allotropic change of β to β' . Another change, to β'' was found at 721° , and this transformation was subject to under-cooling. The α -phase boundary was detd. by annealing and quenching expts., the temps. being measured accurately within 10° . A period of 7 days was allowed for equil. at 400° , and less time at higher temps. Typical microstructures and an equil. diagram up to 8% Si are shown. The solidus extends in a smooth curve to 5.25% Si at 852° . Between 782° and 721° , the α -phase extends to 6.7% Si, but the boundary slopes back to 4.1% at 400° . The best etching reagent was found to be a satd. soln. of $K_2Cr_2O_7$ with 10% concd. H_2SO_4 and 2% of a

satd. soln. of NaCl. Markings in the α resembling Neumann bands were found on deep etching. The β tends to segregate to the first-formed nuclei. G. F. C.

X-ray analysis of Heusler alloys. ELIS PERSSON. *Naturwissenschaften* 16, 613 (1928).—Harang (C. A. 21, 3776) claimed that the properties of Heusler Al bronzes (Cu, Mn, Al alloys) can be derived from Mn-free Al bronzes (12% Al) with a complicated lattice (γ type, 52 atoms) and that the magnetic qualities cannot be explained by a single lattice. P. examd. these alloys with x-rays and found a special β modification: the primary lattice is body-centered cubic, like α iron, while the Al atoms occupy points of a free-centered cube of double the parameter. The elementary cube cell contains 16 atoms, 12 of which are Cu and Mn, thus confirming the formula $(\text{Cu, Mn})_3\text{Al}$. Magnetic alloys always give lines of the special β structure, which can be considered the carrier of magnetism. In order to be magnetic a minimum of Mn has to be present, alloys low in Mn, chilled, give simple β structure without the special placing of Al atoms and are non-magnetic. On annealing they become magnetic and α - and γ -phases (α is face-centered cubic) sep. out, leaving a Mn-rich β -phase. The strongest magnetism is found in chilled alloys of high Mn content. Indications of a fourth phase, not related to magnetism, were found. B. J. C. VAN DER HOEVEN

The complex structure of copper-tin intermetallic compounds. J. D. BERNAL. Univ. of Cambridge. *Nature* 122, 54 (1928).—Preliminary results of x-ray analyses show that although δ -, η - and ϵ -bronzes are composed of definite intermetallic compds., their structures and compns. are more complex than those usually given them. δ -Bronze has a close-packed cubical structure with a face-centered lattice, confirming previous observations. With the aid of Bradley and Thewlis' (C. A. 21, 48) values for γ -brass, the total no. of atoms in a cell is calcd. as 416. As this no. cannot be made up of Cu_3Sn mols., the simplest formula corresponding to a d. of 8.95 is most probably $\text{Cu}_{10}\text{Sn}_{11}$. Micrographic analyses give 20.6 at. % Sn, agreeing closely with the x-ray value. X-rays show that η -bronze has a complex, close-packed hexagonal structure, in harmony with the results of others. The accepted compn. (Cu_5Sn) is probably correct, analysis of the crystals giving 25.2 at. % Sn, or 16 mols. of Cu_5Sn per cell. Micrographically, 24.3 at. % Sn is obtained, which agrees more closely with $\text{Cu}_{10}\text{Sn}_{16}$. ϵ -Bronze shows a NiAs structure. Analyses of the crystals give 45 at. % Sn, 46 at. % being obtained micrographically. With a d. of 8.27 the simplest formula would be Cu_8Sn_9 . Further study is required to obtain exact nos. The complexity shown by these compds. is due to an incommensurability in the at. diams. these being incapable of adjusting themselves in less than a given no. of at. diams. J. BALOZIAN

Improvable silver alloys. W. FRAENKEL AND P. SCHALLER. Frankfurt Univ. Z. Metallkunde 20, 237-43 (1928).—Cu-Ag alloys in the rolled condition with Ag content between 80 and 97% were examd., Brinell hardness, tensile strength and elec. cond. being detd. after various methods of heat treatment. When an alloy contg. 8% Cu is heated for 12 hrs. just under the eutectic temp. (725°), and is then quenched in cold H_2O , the Brinell no. (500 kg. load) is about 51. If it is then annealed at 287°, the Brinell no. rises to a max. of 107 in 1.5 hrs., after which it falls very slowly. With lower annealing temp. the hardening effect is slower and with higher annealing temp. much faster. Thus at 350°, the max. hardness is attained in 20 min. If the alloy is not quenched but slowly cooled from 725°, the Brinell no. is 57, only slightly higher than for the quenched material, while if the primary heat treatment is conducted at lower temps., lower values of hardness are obtained. The effects upon tensile strength and sp. elec. cond. are similar to the effect upon hardness. Thus for the 8% Cu alloy, tensile strength in the quenched condition is 24 kg./sq. mm., annealed 1.5 hrs. at 280° it is 41.3 kg./sq. mm. Sp. elec. cond. quenched is 45.4×10^{-4} , annealed 1.5 hrs. at 280° 52.1×10^{-4} . The same expts. are repeated with alloys contg. approx. 3, 4, 5, 6.5, 8.0, 10 and 20% Cu, the max. hardening effect being obtained with the 8% alloy. This hardening effect followed by softening encountered when Cu-Ag alloys are annealed after quenching from 725°, is explained on the basis of the greater soly. of Cu in Ag at higher temps. and the slip-interference theory. The same behavior is shown by cast alloys, but the degree of hardening obtained is less. H. STORRTZ

The strength of a cadmium-zinc and of a tin-lead alloy solder. C. H. M. JENKINS. Natl. Phys. Lab. Teddington, Eng. J. Inst. Metals (advance copy), No. 479, 19 pp. (1928).—The resistance to failure under prolonged stress of the Cd-Zn eutectic, contg. 82.6% Cd, was compared with that of the common 60-40 Sn-Pb solder. Creep in these alloys may occur at room temp., but satisfactory service may be obtained at higher temp. Test specimens of the cast and rolled alloys were prepd. and tested in tension after various periods of aging or annealing. The Cd-Zn alloy showed about 3 times the tensile strength of the Sn-Pb solder, and equal ductility. Low-temp. annealing

for a week raised the strength of the former. Each alloy was weakest in the cold-rolled state, thin chill castings being much stronger. Under prolonged stress at room temp., the Cd-Zn alloy was 6 times as strong as the Sn-Pb solder, the cast material being again the strongest. The Sn-Pb solder failed within a year under only 100 lb. per sq. in. Under prolonged stress at 120°, the Cd-Zn alloy was about as strong as the other at room temp. Freshly rolled material was less resistant to stress at 120° than aged material. No intercrystalline cracking occurred in these tests on the Cd-Zn alloy. The strength of the film in a soldered joint with these alloys is probably about the same as the strength of a chill casting. G. F. C.

Properties and production of aluminum alloy die-castings. S. L. ARCHBUTT, J. D. GROGAN AND J. W. JENKIN. Natl. Phys. Lab., Teddington, Eng. *J. Inst. Metals* (advance copy), No. 477, 19 pp. (1928).—Tensile test-specimens and T-shaped tubular castings were made in cast-Fe molds with Ni-steel cores from Al alloys contg., resp., 4% Cu, 8% Cu, 12% Si, 4% Cu plus 2% Ni plus 1.5% Mg (Y alloy), and 4% Cu plus 3% Si. The molds were coated with a spray of whiting in dil. Na₂SiO₃ soln.; the cores by dipping into a suspension of plumbago and rouge in water. The operations of pouring, extn. of the cores, opening of the mold, and removal of the casting, had to be accurately timed. To avoid unsoundness, the test-bars were poured horizontal, with a riser over each end. The binary Cu alloys gave more trouble from cracking than the others. The best casting conditions were worked out for each alloy, and the castings were tested for soundness, d. and strength. The "Y" alloy was strongest, and the 12% Si alloy most sound. The hot-shortness of these alloys, and also of Al contg. 2.75% Cu plus 13.5% Zn, was detd. by impact tests of specimens at various temps. from 516° to 580°. The specimens were heated in special holders in an elec. furnace, and from a thermocouple in a dummy specimen the testing temp. was found to be 6° lower than the temp. of withdrawal from the furnace. The presence of liquid in the tested specimens was detd. by the microscope after quenching, and the changes in impact resistance with temp. near the point of incipient melting are plotted as curves. The 12% Si and the "Y" alloys showed the best shock resistance near the m. p., and the 8% Cu and the 13.5% Zn alloys showed the least. The former also gave good results in tensile tests of die-cast bars not machined. Tables of mech. properties and photomicrographs are included in the paper. Also in *Engineering* 126, 342-5 (1928). G. F. C.

The treatment of aluminum and aluminum alloys with chlorine. D. R. TULLIS. *J. Inst. Metals* (advance copy), No. 480, 8 pp (1928)—Al and Al alloys are shown to dissolve gases, chiefly H₂, and by the addn. of Mg, Zn or Ca the gases are thrown out of soln. and cause unsoundness. Archbutt's method of solidification and remelting to remove gases is described. An Al alloy contg. 14% Zn was made and remelted in small portions, adding Ca or gassing with Cl or both. Gassing with Cl was more effective in promoting soundness and high sp. gr. than Archbutt's method. Gassing with Cl for 4 min. increased the sp. gr. 2%. Similar results were obtained in Al alloys contg. Si or Ca or both. In Al alloys contg. 10 or 15% Fe, gassing with Cl practically stopped extrusion of liquid during solidification, but the treatment was not effective in an alloy contg. 20% Fe. An alloy of Al with 60% Mn cracked and disintegrated on aging less rapidly when treated with Cl than without treatment. The disintegration is probably due to dissolved gases. G. F. C.

The equilibrium diagram of the aluminum-calcium system. KANJI MATSUYAMA. *Science Repts. Tôhoku Imp. Univ.* 17, No. 4, 783-9 (1928).—Thermal analyses were made on 10-g. samples of Ca-Al alloys heated and cooled *in vacuo*, and changes in elec. resistance with varying temp. were also measured. Photomicrographs are shown of typical alloys etched with 10% KOH, and an equil. diagram of the complete series is given. The liquidus shows a max. at 1079° with 42.5% Ca, the compn. of CaAl₂. A eutectic between the solid soln. of Ca in Al and CaAl₂ occurs at 7.55% Ca and 616°, and another between CaAl₂ and Ca at 73% Ca and 545°. A peritectic reaction occurs at 700° in alloys contg. 13.9 to 42.5% Ca, forming CaAl₂ on cooling, from CaAl₂ and the liquid. Al dissolves 0.6% Ca at 616°, and 0.3% at room temp. G. F. C.

Decorative green finishes. HECTOR C. HEGGIE. *Metal Ind.* (London) 32, 513 (1928).—Recipes are given for producing on Cu and Cu alloys yellow-green, blue-green, dark brownish black and dark greenish black patinas; also a process for a green finish by electroplating. E. G. R. ARDAGH

Apparatus (of the open pan type) for roasting and agglomerating ores. Soc. ANON. LE PROQUES ET METALLURGIQUE AND A. DE SAMSONOW. Brit. 283,133, Jan. 4, 1927.

Selective flotation of minerals. BAYARD S. MORROW and ERNEST KLEPETKO. U. S. 1,683,569, Sept. 4. A soln. comprising cresylic acid and thiocarbamilide is used as a flotation agent in the treatment of ores such as those contg. Pb, Zn and Hg.

Extracting copper from its ores. ALEXANDER ELLIOTT. U. S. 1,681,528, Aug. 21. A Cu ore such as oxide or oxidized ore is subjected to the action of a soln. of FeSO_4 in the presence of air which is distributed in intimate contact with the soln. and under superatm. pressure which is maintained throughout the body of the soln. and ore mixed with it. An app. is described.

Stereotype foundry plant. HENRY A. WISE WOOD (to Wood Newspaper Machinery Corp.). U. S. 1,682,161, Aug. 28. Structural features.

Apparatus for tapping molten metal under pressure. JOSEF POLAK. Fr. 634,879, May 23, 1927. The tube for the ascent of the molten metal to the mold is heated directly by conduction and radiation from the molten metal.

Ladle lining. JAMES V. MARSHALL (to New Castle Refractories Co.). U. S. 1,681,943, Aug. 28. A cup-shaped lining of refractory material is shaped so as to be adapted for insertion in a ladle for holding molten metals.

Cast iron. AUGUSTUS F. MEEHAN. U. S. 1,683,086, Sept. 4. Gray molten metal is treated with a silicic contg. an alk. earth metal such as Ca and another graphitizing agent such as Ni. Mg and Al also may be added.

Cast iron. AUGUSTUS F. MEEHAN (to Mechanite Metal Corp.). U. S. 1,683,087, Sept. 4. Metallic Ca, in proportion to the amt. of graphitization desired, is added to molten iron which if cast would contain more than 2% of combined C.

Casting ferrous metal cylinders. NELSON LITTELL. U. S. 1,683,475, Sept. 4. In casting ferrous metal cylinders with a chill-hardened inner surface and an unhardened exterior, molten metal is introduced into a refractory mold around a rigid chill core, and the core is withdrawn after the core-contacting skin of the casting has solidified but before the casting shrinks upon the core; withdrawal of the core commences soon after the pouring of the metal is started and continues until after the pouring is completed.

Use of aluminum casting cores to facilitate cooling of cast stereotype plates. HENRY A. WISE WOOD (to Wood Newspaper Machinery Corp.). U. S. 1,682,160, Aug. 28.

Magnetic core material. STUART BALLANTINE and RICHARD W. SEABURY (to Radio Frequency Laboratories, Inc.). U. S. 1,682,364, Aug. 28. Thin laminae of magnetic material such as mill scale from Si-steel are coated with a potentially reactive phenolic resinoid insulating binder and the material is subjected to heat and pressure in a mold under conditions which produce a product of low elec. cond. and having a magnetic permeability at radio frequencies of the order of 10.

Ore-roasting furnace with an endless traveling conveyor. MILTON E. BRANTHAVER (to American Milling & Refining Co.). U. S. 1,681,695, Aug. 21. U. S. 1,681,696 relates to similar app. in which the roasted ore is discharged into a vat contg. water.

Open-hearth furnace. FRANK B. MCKUNE (to Open Hearth Combustion Co.). U. S. reissue 17,071, Aug. 28. Original pat. No. 1,339,855 (C. A. 14, 1961) was issued May 11, 1920.

Open-hearth furnace construction. ALBERT T. KELLER (to Bethlehem Steel Co.). U. S. 1,682,378, Aug. 28.

Furnace adapted for smelting ores or concentrates. HOWARD W. HALL (to American Smelting & Refining Co.). U. S. 1,681,535, Aug. 21.

Smelting furnace with cupola and horizontal hearth portions. JAMES A. LANIGAN. U. S. 1,682,343, Aug. 28. A furnace is specified, adapted for smelting ferrous or non-ferrous metals.

Rotary furnace using powdered fuel for melting metals or for smelting. C. BRACK-ELSBURG. Brit. 283,381, March 9, 1927. Structural features.

Recovery of metals from alloys, etc. FRANZ BISCHITZKY. Fr. 635,034, May 26, 1927. Sn, Pb, Cu, Sb, Bi and Zn are recovered from waste alloys by dissolving in HCl, the HCl being used on the counter-current principle, and salts having a catalytic action such as CaCl_2 are added. The chlorides of the heavy metals are continually pptd. and the soln. becomes richer and richer in Sn. The CaCl_2 used is obtained by the pptn. of the Sn with lime.

Alloys. PIERRE BERTHELEMY and HENRY DE MONTBY. Fr. 634,751, May 20, 1927. In order to obtain a homogeneous distribution of Cd in Al, a final addn. of Cd and Mg or Cd, Al and Mg is made to fused Al or Al alloy. Similarly for Mg alloys, an addn. of Cd and Al is made to the fused metal. The alloys obtained are unaffected by sea water or air. Cf. C. A. 21, 1442.

Aluminum alloys. DEUTSCHE VERSUCHSANSTALT FÜR LUFTFAHRT E. V. Brit. 282,701, Dec. 27, 1926. Al alloys contg. Cu and Mg are made from chem. pure or electrolytically refined Al so as to be free from Fe, with addn. of Si necessary for the formation of Mg_2Si . The Si may be added as an Al-Si alloy also made from pure Al.

Aluminum alloys. TH. GOLDSCHMIDT A.-G. Fr. 634,885, May 23, 1927. See Brit. 272,706 (C. A. 22, 1754).

Iron-nickel-chromium alloys. Y. KAMISHIMA. Brit. 283,354, Feb. 9, 1927. Alloys are formed contg. Ni 1-5, Cr 7-20 and Si 1-6%, together with Fe, as low as possible in C. The alloys may be made in an elec. furnace by melting Cr or ferro-Cr, Ni, ferro-Si and Fe, with a flux of CaF_2 , NaHCO_3 and glass.

Nickel-cobalt-iron alloys. W. S. SMITH, H. J. GARNETT and J. A. HOLDEN. Brit. 282,901, Oct. 1, 1926. Alloys are formed of Ni 55-65, Co 20-30 and Fe 15-25%, with or without 1-5% of another element to increase the elec. resistance such as Cr, V, W, Si, Al, Mo or Cu. A small quantity of a deoxidizer such as Mg, Cd, Al or Mn may be added.

Cleaning and burnishing metallic powders. JOHN A. DALY. U. S. 1,681,521, Aug. 21. Finely divided metals such as Pb-Sn alloy are agitated with harder finely divided material, *e. g.*, with glass beads or steel particles.

Alloy steel. HENRY B. ALLEN (to Henry Disston and Sons). U. S. 1,681,797, Aug. 21. A high-C tool steel which is suitable for making saw blades contains as alloying elements only Ni 1.0-1.5 and Mo 0.1-0.7%.

Steel. VEREINIGTE STAHLWERKE A.-G. Fr. 534,736, May 20, 1927. A steel for use in bridge construction, etc., and which is resistant to corrosion, contains Si 0.5 to 1.5 and Cu 0.1 to 0.5%.

High-speed steels. STAHLWERK BECKER A.-G. Brit. 282,744, Dec. 30, 1926. In high-speed steels contg. V or Co or both, the C content is increased above 0.6% by 0.16% for each 1% of V and by 0.04% for each 1% of Co.

Apparatus for tempering steel strips or other metal articles. HENRY J. GAISMAN and CONRAD SCHUMACHER (to Autostrop Patents Corp.). U. S. 1,683,129, Sept. 4.

Annealing iron and steel. E. H. SCHULZ and W. HULSBRUCH (to Vereinigte Stahlwerke A.-G.). Brit. 283,200, Jan. 8, 1927. Edge or sulfate decarburizing is prevented by conducting the annealing in an atm. comprising a mixt. of carburizing gases such as CO , CH_4 and coke-oven gas and decarburizing gases such as blast-furnace gas and N_2 , so constituted that for Fe and steel generally or for any or only certain temps. no carburizing or decarburizing takes place. Examples are given.

Apparatus for bright annealing of wire, metal strips, etc. JAMES E. ROBERTSHAW (to American Steel and Wire Co. of N. J.). U. S. 1,682,801, Sept. 4.

Increasing the conductivity of metals. SAMUEL RUBEN. U. S. 1,683,209, Sept. 4. A metal body such as a Cu wire is heated to a temp. somewhat below its m. p. by an elec. current which is passed through it, in an electromagnetic field parallel to the direction of the elec. current discharge. An app. is described.

Coating metal surfaces. L. E. BARRINGER (to British Thomson-Houston Co., Ltd.). Brit. 283,182, Jan. 5, 1927. Before coating metals with "a cellulose or other lacquer," there is applied a preliminary coating of a polyhydric alc.-polybasic acid resin such as a glycerol-phthalic acid resin. Numerous details are given.

Etching solution. JOHN W. SAUER. U. S. 1,681,499, Aug. 21. A soln. suitable

for etching metals for decorative purposes is formed of water 1 gal., CuSO_4 2 oz., HNO_3 0.25 oz., HCl 0.25 oz., FeSO_4 0.25 oz. and NaCl 8 oz.

Rolling hot packs of metal sheets. JOHN B. TYRUS (to American Rolling Mill Co.). U. S. 1,683,003, Sept. 4. Mech. features.

Apparatus for making metal tubes or other seamless, tapered, bent, drawn metal articles. CARL BERGMANN, JR. (one-half to Gustave R. Thompson). U. S. 1,683,123, Sept. 4.

Metallic tungsten. KOJI ANJOW (to Mitsubishi Kogyo Kabushiki Kaisha). U. S. 1,682,058, Aug. 28. In order to effect its purification, crude metallic W is heated under pressure with an aq. alkali soln., *e. g.*, heated with a 15% soln. of NaOH at 150° for a half hr.

Detinning. Q. MARINO. Brit. 282,779, Dec. 27, 1926. Detinning of tin scrap or the like is effected by immersion for a few min. at ordinary temp. in a bath of 21°Bé . HCl to which a Cl -releasing salt has been added such as Na or K chromate or dichromate or nitrate or chlorate. Sn may be pptd. from the resulting SnCl_2 soln. by Zn or Al or the soln. may be evapd. to dryness and the product dissolved with dil. H_2SO_4 and subjected to electrolysis to obtain spongy Sn .

Welding rod. PLINY P. PIPES (to Ohio Brass Co.). U. S. 1,681,904, Aug. 21. A rod suitable for use in welding Cu to steel comprises Cu together with P 0.1–0.2 and Sn 0.5–1.0%.

Burner (using vaporized liquid fuel and oxygen) for welding or cutting metals. F. W. BECKER. Brit. 283,415, June 20, 1927.

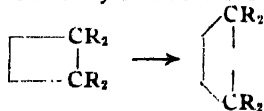

Apparatus for supplying oxygen to welding or metal cutting apparatus. ROBERT WEBER (to Le Petits Fils de François de Wendel & Cie.). U. S. 1,683,112, Sept. 4.

Composition for use with electrodes for welding or coating iron or steel. ANDREW C. JAMES. U. S. 1,682,524, Aug. 28. Mn 20, Cr 20, Ti 20, Mo 5 and Na silicate 35%.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

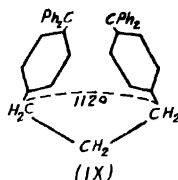

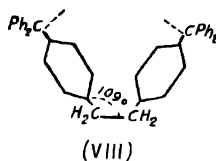

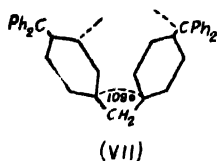

Ring strain and radical formation. GEORG WITTIG AND MARTIN LEO. *Ber.* 61B, 854–62(1928).—In the radical disocn. of certain hexasubstituted ethanes several factors are probably involved, especially the space occupied by and the valence requirements and electrochem. character of the substituents. On the assumption that the amount of valence which acts between the 2 ethane C atoms and which depends on the valence requirements and electrochem. character of the substituent holds these C atoms at only the normal distance from each other (1.54×10^{-8} cm.), all forces which tend to increase this distance will lead to a cleavage of the mol. if they are great enough. In the hexaarylethanes the filling of the space by the substituents is probably responsible for the two C atoms not being able to lie at the normal distance from each other. But in strained ring systems, also, it must be assumed that there are forces which tend to increase the distance between the ring atoms. It seemed of interest, therefore, to study, on suitably substituted C atoms, the disocn. tendency of a C—C union within a ring

A rupture of the ring must necessarily lead to the forma-

tion of a chain with 2 unsatd. C atoms. A few such "diradicals" have already been described and it is because of the appearance of a paper by Diltthey (*C. A.* 22, 769) that W. and L. publish their results in their present incomplete form. From CH_2Ph_2 and $(\text{CH}_2\text{Ph})_2$, resp., they obtained with BzCl by the Friedel-Crafts method the ketones $\text{CH}_2(\text{C}_6\text{H}_4\text{COPh})_2$ (I) and $(\text{CH}_2\text{C}_6\text{H}_4\text{COPh})_2$ (II); that the Bz groups enter the *p*-position to the CH_2 group was shown by the fact that (*p*- $\text{H}_2\text{NC}_6\text{H}_4$) $_2\text{CH}_2$ gives by the Sandmeyer method a dinitrile which by the Grignard reaction yields a $\text{CII}_2(\text{C}_6\text{H}_4\text{Bz})_2$ identical with I. The diketones with PhMgBr gave the glycols $\text{CH}_2(\text{C}_6\text{H}_4\text{C}(\text{OH})\text{Ph})_2$ (III) and $[\text{CH}_2\text{C}_6\text{H}_4\text{C}(\text{OH})\text{Ph}]_2$ (IV). Only IV crystd. but both III and IV yielded with HCl gas under the proper conditions well crystd. chlorides (V and VI) which, colorless in themselves, showed in hot AcOH a greenish color disappearing on cooling. On removal of the halogen with "Naturkuper C" or Hg in C_6H_6 the chlorides formed beautifully colored solns. sensitive to air, the *p,p'*-bis[diphenylmethyl]diphenylmethane (VII) giving a bright red, the ethane (VIII) a dark blue-violet soln. On addn. of petro-

leum ether (under N), both solns. deposit faintly yellow flocks which redissolve in excess of C_6H_6 with the original color. When exposed several hrs. to sunlight the radicals are

decompd. and decolorized. Mol.-wt. detns. (f.-p. method) showed that the radicals dissolve chiefly in the monomeric form in C_6H_6 (only about 20-30% dimer). Since $Ph_2C(MeC_6H_4)C$, like Ph_2C , under the same conditions is for the most part dimerized, it seems plausible to ascribe the greater dissocn. tendency of VII and VIII to the concurrent effect of ring strain, as developed above. It can be seen from models that a mutual satn. of the 2 "tervalent" C atoms is prevented by the ring strain if it is assumed that the C atoms joined directly to the C_6H_5 ring lie in the same plane with it, whereas in the propane deriv. (IX) the unsatd. C atoms can neutralize each other (not wholly without strain), a deduction whose exptl. confirmation is being studied. Attempts to prep. the substance $(Ph_3CCPh_2C_6H_4CH_2)_2$ from Ph_3CNa and VI gave only the dark violet soln. of VIII, which was pptd. in flocks by petroleum ether. The tremendous sensitivity of VII and VIII, to O is shown by the fact that, after filtering in N, the solid powdery ppts. quickly resinify in the air and then have the same compn. as the oxidation products obtained by treating the C_6H_5 solns. with air; mol. wt. detns. and analysis indicate that VIII takes up 1, VII for the most part 2 atoms of O while maintaining its monomeric form. Attempts to bridge the unsatd. C atoms through an intramol. hydroquinone ether by treatment with quinone were without result; the solns. were decolorized but nothing crystd. Since ring strain seems to favor the tendency to dissociate, it seemed possible that compds. of the type of the sym. tetraaryldialkylethanes, which lie at the limits of the ethanes capable of dissociation, might, under the influence of ring strain, dissociate into radicals with accompanying color phenomena. II with $MeMgI$ gave the cryst. glycol $(CH_2C_6H_4C(OH)MePh)_2$ (X) whose esterification offered considerable difficulty on account of the ease with which it loses H_2O to form the unsatd. hydrocarbon $[CH_2C_6H_4C(:CH_2)Ph]_2$ (XI), but after standing 1 week in $MeOH$ contg. a trace of HCl it yielded the *di-Me ether* (XII) which with $Na-K$ in dioxane gave the brown *di-K compd.* (XIII), yielding with $EtCH(C_6H_4CHMePh)_2$ (XIV). On removal of the K from XIII with $(CMe_2Br)_2$, there was instant decolorization without any even transitory color change and from the soln. was isolated a white powder (XV) having an extraordinarily high mol. wt.; apparently 3 of the diradicals combine to a substance surprisingly stable towards Br and oxidizing agents. *p,p'*-Dibenzoyldiphenylmethane (I) (50% from CH_2Ph_2 and $BzCl$ with $AlCl_3$, or 12 g. from 10 g. $CH_2(C_6H_4NH_2)_2$ through the dinitrile with $PhMgBr$), faintly yellowish, m. 147.5-5.5°. *p,p'*-Bis[diphenylhydroxymethyl]diphenylmethane (III), resin turned red by concd. H_2SO_4 ; dichloride (V) (6-7 g. from 9 g. I), m. 157-60°. VII, mol. wt. in freezing C_6H_6 661. *p,p'*-Dibenzoyl- α,β -diphenylethane (II) (yield, 50%), m. 174.5-6°. *p,p'*-Bis[diphenylhydroxymethyl]- α,β -diphenylethane (IV), m. 176-8°, shows red halochromism in concd. H_2SO_4 ; dichloride, (VI) (12.5 g. from 15 g. IV), m. 184-6° (decompn.), gives a dark green color with concd. H_2SO_4 , also in *o*-cresol and in $AcOH$ on heating, and a violet color in $PhNMe_3$ and $BzOEt$, the solns. becoming colorless on cooling. VIII, mol. wt. in C_6H_6 588. *p,p'*-Bis[phenylmethylhydroxymethyl]- α,β -diphenylethane (X), m. 113-4.5°, instantly gives in hot $AcOH$ *p,p'*-bis-[α -phenylethenyl]- α,β -diphenylethane (XI), m. 117-9°, decolorizes Br in $CHCl_3$. XII, m. 144-8°, gives XI on long boiling with $AcOH$. *p,p'*-Bis-[α -phenylethenyl]- α,β -diphenylethane (XIV), m. 97-8°, does not decolorize Br in $CHCl_3$. XV, $(C_{20}H_{14})_n$, m. 110-5°, mol. wt. in freezing C_6H_6 1050-1170.

C. A. R.

The constitution of citronellol and rhodinol. I. V. GRIGNARD AND J. DOEUVRE. *Compt. rend.* 187, 270-3(1928).—G. and D. study the structure of citronellol (I), and rhodinol by ozonization to det. the CH_2 and Me_2C groupings. Samples of I from widely varying sources contain in every case 18-28% α -form and 72-82% β -form. I in $HOAc$ with H_2O for 40 hrs. at 0° gives menthogycol (II), b. 115-8°, m. 65-6°, and a monoacetate. II rearranges to isopulegol with Ac_2O or 10% H_2SO_4 . The cyclization of I prevents its quant. ozonization in $HOAc$, but C_6H_5N gives good results.

D. H. POWERS

The affinity of hydrocarbon groups for oxygen. RAGNAR LYDÉN. Univ. Helsingfors. *Finska Kemistsamfundets Medd.* 35, 19-36(1926); *Chem. Zentr.* 1927, I, 1813-4.—A series of ethers was decompd. according to the Aschan method by heating with AcBr in a sealed tube, the reactions being: $ROR' + AcBr \rightarrow RBr + AcOR'$, and $ROR' + AcBr \rightarrow R'Br + AcOR$. With a mixed ether, the reaction can therefore proceed in 2 directions, and the same result may be attained by using a mixt. of 2 simple ethers. The hydrocarbon group, which together with the ether O unites with the Ac group to form an ester, has a greater energy of combination with the ether O than the group forming the Br-substituted hydrocarbon. These energies of combination are compared by detns. of the reaction products. For the conversion of equimol. quantities of 2 ethers with AcBr, the following reaction is carried out: $R_2O + R'_2O + AcBr \rightarrow xRBr + xAcOR + yR'Br + yAcOR' + (1-x)R_2O + (1-y)R'_2O + [1-(x+y)]AcBr$. *Exptl.*—Et₂O, (iso-Am)₂O and AcBr were heated together 24 hrs. in a sealed tube at 200-10°, fractionally distd. and the individual fractions analyzed by detg. the unaltered AcBr and the Br and by sapon. The O-affinity of Et/iso-Am was 1/2.56(1/2.193). With iso-AmOEt and AcBr, the O-affinity of Et/iso-Am was 1/2.183. With Et₂O, phenetole and AcBr, the ratio AcOEt/EtBr was 1/1.959(1/2.077). With (iso-Am)₂O, phenetole and AcBr, the ratio EtBr/iso-AmBr was 1/10.6. C. C. DAVIS

New method of obtaining neutral esters of sulfuric acid. R. LEVAILLANT. *Compt. rend.* 187, 234-6(1928).—ROSO₂Cl reacts with RONO to form R₂SO₄ with the evolution of NOCl. MeONO (I) is passed through MeOSO₂Cl (II) heated in a bath initially at 80° at such a rate that the reaction temp. is maintained 20° above that of the bath, which is allowed to rise to 120° during the course of the reaction. 1.1 mol. of I per mol. of II is conducted into the reaction flask. After cooling the product is washed with ice water, dried over anhyd. Na₂SO₄ and distd. under diminished pressure, giving 40% of *di-Me sulfate*, b₁₀ 80°, d₄ 1.349-1.350, n_D¹³ 1.389. *Di-Et sulfate* was prepd. in the same manner, yield 55%, b₁₀ 97-8°, d₄ 1.202, d₁₆ 1.186, n_D¹⁴ 1.4022. Though the method is not practical for these esters, it is suggested as a general method for the prepn. of R₂SO₄. A. S. CARTER

The reactions of activated magnesium. I. A. P. TEREŦ'EV. *J. Russ. Phys.-Chem. Soc.* 60, 85-9(1928).—Dry Mg activated by heating with 0.04 its wt. of I forms alcohols readily; Me₂CHCH₂CO₂Me in abs. EtOH is transformed by Mg into the Et ester after 4-5 hrs.' boiling. Reduction does not take place. A soln. of 2.4 g. activated Mg in 50 cc. abs. EtOH was boiled for 1 hr. with 32 g. CH₂(CO₂Et)₂, 13 g. Et₂SO₄ added and heating continued for 4 hrs.; 22 g. EtHC(CO₂Et)₂ was obtained. II. **Reactions with ammonia.** *Ibid* 91-3.—After 5 hrs. with NH₃ at 350-500°, activated Mg (cf. above) gives a grayish yellow powder besides 2.5% Mg. The powder contg. 30.17% N is composed of 5-6% MgI₂, about 8% MgO and, probably, Mg(NH₂)₂. It reacts readily with H₂O, alcs. and amines, and with pyrrole on warming; very slowly with C₆H₅N vapor at 250°, not at all with EtOAc, AcCl and Me₂SO₄. Mg(NH₂)₂ reacts at 130-50° with PhNH₂, PhNHMe, Ph₂NH, *o*-H₂NC₆H₄OMe, α - and β -C₆H₇NH₂ and AcNHPh. With PhNH₂ vapor, the reaction begins at 240°. III. **The action of *o*-anisidine.** A. P. TEREŦ'EV AND A. M. RUBINSTEIN. *Ibid* 95-101.—Activated MgI₂ was slowly added to 2 equivs. boiling *o*-MeOC₆H₄NH₂ in a CO₂ atm. Upon cooling to 150°, CO₂ was passed in and crystals of Mg 2-methoxycarbamate sepd. After 2-4 hrs. more at 250-70° the product was washed with cold xylene, dissolved in HCl and pptd. with NaOAc; colorless plates, m. 178°, forming a cryst. HCl salt, sol. in hot H₂O, PhH, EtOH, Et₂O and AcOH. Aq. solns. darken on contact with air, reduce Ag(NH₂)₂NO₃, give a red color with FeCl₃. A m.-p. depression is obtained with (MeOC₆H₄NH)₂CO. Hence the compn. corresponds to 2,3-MeO(2'-MeOC₆H₄NHCO)C₆H₄NH₂ (I). On boiling with HCO₂H are obtained crystals, m. 133°, and more stable toward O₂ than I. Analysis agrees with the formula 2,3-MeO(2'-MeOC₆H₄NHCO)C₆H₄NHCHO (II). I was boiled with NaOH, *o*-MeOC₆H₄NH₂ was steam-distd. and the mother liquor treated with AcOH; 2,3-MeO(H₂N)C₆H₄CO₂H (by analysis), m. 153°, resulted. It was sol. in acids and alkalies, hot H₂O, EtOH, Et₂O and PhH, colored FeCl₃ solns. red-violet, reduced Ag(NH₂)₂NO₃ and formed a sparingly sol. Cu salt. The acid was diazotized and reduced with Sn in alk. soln., treated with H₂S, evapd. and the residue distd. CH₂.C₆H₄.CO.O (III), m. 72°, re-

sulted (cf. *Ber.* 10, 1466(1877); 25, 524(1892)), which with alk. KMnO₄ gave *o*-C₆H₄(CO₂H)₂, identified by converting it to fluorescein. BASIL C. SOVENKOFF

α -Chloro- and α -bromo- α -sulfopropionic acids and their optical resolution. H. J.

BACKER AND H. W. MOOK. *Bull. soc. chim.* 43, 542-9 (1928).—These acids have been synthesized by 2 methods and then resolved into their optically active forms. The first method of synthesis consists in the sulfonation of α -chloro- and α -bromopropionic acids by treatment with SO_3 at 100 – 120° , the yields of the Ba salts being 25 and 30%, resp. The 2nd method involved the halogenation of $\text{MeCH}(\text{SO}_3\text{H})\text{CO}_2\text{H}$ by heating with Br and water (for bromination), the yields of the Ba salts being 70 and 80%, resp. The acids obtained by both methods are identical. α -Chloro- α -sulfopropionic acid (I) gives hygroscopic crystals contg. 1 mol. water and m. 93 – 4° . Ba salt, contains $3\text{H}_2\text{O}$, soly. 2.88 g. anhyd. salt in 100 g. water at 25° . α -Bromo- α -sulfopropionic acid (II), hygroscopic crystals contg. 1 mol. water, m. 105 – 110° . Ba salt, contains $3\text{H}_2\text{O}$, soly. 4.36 g. anhyd. salt in 100 g. water at 25° . The Th and K salts of both acids crystallize free from water. The acids were resolved into active forms by means of their strychnine salts which were prepd. by treating their Na salts with strychnine acetate. I shows $[\text{M}]_D^{25} 9.5^\circ$; neutral salt (bivalent ion) $[\text{M}]_D^{25} 26.1^\circ$. The corresponding values for II are 1.2° and 12.5° , resp. These active acids do not racemize on heating for a long time at 100° , showing them to be quite different from the correspondingly substituted acetic acids, which tend to racemize so quickly that it is difficult to isolate their active forms.

New esters of α -bromobutyric acid. VENANCIO DEULOFEU. *Bull. soc. chim.* 43, 549–51 (1928).—Three new esters of this acid have been prepd. by the action of the corresponding alcs. on the acid with H_2SO_4 as a catalyst: Pr, b. 190.5 – 194° , yield 50%; iso-Pr, b. 179 – 82° , yield 30%; allyl, b. 189 – 93° , yield 25%. F. C. H.

Preparation of hydrazine by Raschig's method. O. YU. MAGIDSON AND I. YA. FRENKEL. *Trans. Sci. Chem. Pharm. Inst. (Moscow)*, No. 6, 25–7 (1923).—Ammonia soln. (d. 0.9, 3 l.) and 5% gelatin soln. (300 cc.) are stirred during the addn. of 2 N-hypochlorite soln. (1.5 l.); the evapd. mixt. is filtered and, when cold, is treated with dil. H_2SO_4 , hydrazine sulfate crystg. out. The presence of a small quantity of H_2SO_4 or HNO_3 is very unfavorable. B. C. A.

The action of picric acid on cycloglycine. A. MOREL, P. PRECEPTIS AND A. GALY. *Compt. rend.* 187, 173–4 (1928).—Equivalent quantities of $\text{C}_6\text{H}_2(\text{NO}_2)_3\text{OH}$ (I) and $\text{H}_2\text{NCH}_2\text{CONHCH}_2\text{CO}_2\text{H}$ (II) in H_2O , boiled and concd. in vacuum, yield the monopicrate of II in yellow monoclinic crystals, the crystallographic data of which are given. When the aq. soln. of I and II is made alk. with $\text{Ba}(\text{OH})_2$, which is removed after heating by means of H_2SO_4 , the same product results upon concn. without reduction of I as is the case when cycloglycylglycine replaces II.

Interactions of picric acid and cycloglycylglycine. A. MOREL AND P. PRECEPTIS. *Compt. rend.* 187, 236–9 (1928).—Yellow crystals of the monopicrate (I) of glycylglycine (II) result upon boiling equiv. quantities of $\text{C}_6\text{H}_2(\text{NO}_2)_3\text{OH}$ (III) and $\text{NH}_2\text{CH}_2\text{CO}_2\text{NHCH}_2\text{CO}_2\text{H}$ (IV) in H_2O and concg. in vacuum. Under these con-

ditions the 2,5-diketopiperazine ring in IV is hydrolyzed to form the free NH_2 in II. In soln. made alk. with $\text{Ba}(\text{OH})_2$, some I is formed, varying in color from yellow to red by reason of a 2nd substance (V) carried down in the pptn. Vis pptd. by addn. of excess $\text{Ba}(\text{OH})_2$ and isolated by pptn. of the Ba with H_2SO_4 as a red compd., sol. in H_2O and alkalis and insol. in Et_2O and CHCl_3 . Failure to give the diazo reaction indicates that it is not a nitroaminophenol, but after reduction with glucose, this test is positive, indicating V to be a product of the partial reduction of II by IV. Its tinctorial properties on cotton and silk, its ability to be pptd. by heavy-metal acetates and its inability to be pptd. by nitron, indicate V to be an azoxy compd., which is confirmed by N detn. and reduction with TiCl_3 . A. S. CARTER

Alanine from pyruvic acid. AUBEL AND BOURGUEL. *Compt. rend.* 186, 1844–6 (1928).—The synthesis of alanine (I) from AcCO_2H (II) and NH_3 is accomplished by shaking a water soln. of NH_3 and AcCO_2NH_4 with colloidal Pd in the presence of H_2 . The colloid is stabilized by use of starch paste. From 4 g. of II is obtained 2.9 g. of I.

Lability of the chains of serine-phosphoric acids. A general reaction for tyrones. SWIGEL POSTERNAK AND THEODORE POSTERNAK. *Compt. rend.* 187, 313–6 (1928); cf. C. A. 21, 1281, 2278, 2476, 2539; Platt and Wormald, C. A. 21, 1212; Bergmann, et al. on rearrangements of peptide-like substances (13 papers).—The general reaction of tyrones is based on the production of AcCO_2H at the expense of the serine-phosphoric acid chains. L. W. RIGGS

A general reaction of amino acids. II. H. D. DAKIN AND RANDOLPH WEST. Scarborough-on-Hudson and Presbyterian Hospital, N. Y. *J. Biol. Chem.* 78, 745–56

(1928); cf. C. A. 22, 3134.—By the action of pyridine and Ac_2O on *glutamic acid*, *aspartic acid*, *histidine* and *tryptophan* substituted acetylaminooacetones were derived. *Methylaspartic acid*, because of the absence of an unsubstituted α -H adjacent to the NH_2 group, gave neither a ketone nor CO_2 . β -Amino acids underwent simple acetylation. The ketone formed from glutamic acid could not be isolated but was converted to *2,5-dimethylpyrazine-3,6-dipropionic acid* by reactions analogous to *Gabriel's* pyrazine synthesis from aminoacetone. This acid is of a type hitherto not prepd. It is sparingly sol. in cold H_2O ; moderately in boiling H_2O . Its aq. soln. just reddens blue litmus. It crystallizes from MeOH in stout prisms, m. $211-3^\circ$, without evolution of gas. The acid gives no diazo reaction nor does it contain any amino N. The acetylaminooacetone of aspartic acid is an amber-like gum. Treated with an excess of PhNHNH_2 in AcOH, it was converted to *diacetyl bishydrazone*, m. $241-3^\circ$. *Phenylserine* warmed on the H_2O bath with Ac_2O and pyridine gave the *azlactone anhydride* of acetylaminocinnamic acid, m. 152° . *Phenyl- β -alanine*, similarly treated, gave a large yield of *acetylphenyl- β -alanine*, m. 161° . *Histidine*, similarly treated, resulted in the evolution of 1 mol. of CO_2 and an acetylmino ketone, which by evapn. with 10% HCl deposited colorless prisms, m. $205-6^\circ$, of 4-imidazolyl-3-amino-2-butanone-2HCl. *Tryptophan* gave an analogous reaction. The *azlactones* of leucine, phenylalanine and aspartic acid reacted with pyridine and AcOH to give acetylaminooacetone derivs. similar to those of the amino acids from which they were prepd. The azlactone of benzoylaminoacetic acid, as anticipated, gave neither CO_2 nor a ketone.

ARTHUR GROLLMAN

Some aromatic derivatives of substituted acetylaminooacetones. H. D. DAKIN AND RANDOLPH WEST. Scarborough-on-Hudson and Presbyterian Hospital, N. Y. *J. Biol. Chem.* 78, 757-64 (1928); cf. C. A. 22, 3134.—The following acetylaminooacetone derivs. were prepd. from aromatic α -amino acids by the action of Ac_2O and pyridine by the method previously described. α -*Phenyl- α -acetylaminooacetoxime*, nacreous crystals, sparingly sol. in H_2O , moderately sol. in alc., m. 152° ; 4-*phenyl-5-methylimidazolone*, sandy rosettes, m. $287-9^\circ$, in sol. in H_2O ; 4-*phenyl-5-methyl-2-thiolimidazole*, thin plates, sparingly sol. in H_2O , soften above 250° , m. $290-5^\circ$; α -*benzyl- α -aminoacetone*, hexagonal platelets, m. 130° ; 2,5-*dibenzyl-3,6-dimethylpyrazine*, m. $92-4^\circ$; 4-*benzyl-5-methylimidazolone*, darkens above 250° ; 4-*benzyl-5-methyl-2-thiolimidazole*, m. $279-80^\circ$; α -*p-hydroxybenzyl- α -acetylaminooacetoxime*, m. $189-90^\circ$; α -*p-hydroxybenzyl- α -aminoacetone-HCl*; 4-*p-hydroxybenzyl-5-methylimidazolone*, m. $243-4^\circ$; 4-*p-hydroxybenzyl-5-methyl-2-thiolimidazole*, m. $273-5^\circ$; and 2,5-*p-dihydroxybenzyl-3,6-dimethylpyrazine*, which by its reaction appeared to be the normally constituted pyrazine.

A. G.

Michael condensation. P. C. MITTER AND A. C. ROY. *J. Indian Chem. Soc.* 5, 33-48 (1928).—The condensation of Et citraconate and $\text{AcCH}_2\text{CO}_2\text{Et}$ in the presence of Na and ether or pure NaOEt affords normally *Et γ -aceto- β -methylpropane- α,β,γ -tricarboxylate*, b₁ 182° (hydrolyzed with loss of CO_2 to γ -aceto- β -methylpropane- α,γ -dicarboxylic acid, m. $119-20^\circ$), and a viscous oil which yields the semicarbazone of *Et γ -methyl-4,6-cyclohexanedione-1,2-dicarboxylate*, m. 235° . Condensation in the presence of alc. NaOEt results in the partial conversion of Et citraconate into Et itaconate (Hope, C. A. 6, 3410), and hence, under these conditions, Et δ -acetobutane- α,β,δ -tricarboxylate, b₁ 166° (corresponding acid, m. $119-20^\circ$, not identical with that obtained from the isomeric ester), and *Et 1-carbethoxy-4,6-cyclohexanedione-3-acetate* (monosemicarbazone, m. 251°) are obtained. The first-named compd., which may also be produced by the condensation of Et itaconate and $\text{AcCH}_2\text{CO}_2\text{Et}$, was considered by Michael to be the normal condensation product. Similar results are given by the use of Et citraconate and $\text{MeCHAcCO}_2\text{Et}$; normal products: *Et γ -aceto- β -methylbutane- α,β,γ -tricarboxylate*, b₁ 185° , and *Et 1,2-dimethyl-4,6-cyclohexanedione-1,2-dicarboxylate* (monosemicarbazone, m. 235°); products obtained in the presence of alc. NaOEt: δ -*acetopentane- α,β,δ -tricarboxylate*, b₁ 175° , and *Et 1-carbethoxy-1-methyl-4,6-cyclohexanedione-3-acetate* (monosemicarbazone, m. 247°). Et fumarate and $\text{MeCHAcCO}_2\text{Et}$ yield *Et γ -acetobutane- α,β,δ -tricarboxylate*, b₁ 149° , and *Et 1-methyl-4,6-cyclohexanedione-1,2-dicarboxylate* (monosemicarbazone, m. 240°). Et citraconate and $\text{NCCH}_2\text{CO}_2\text{Et}$ condense (through the intermediate formation of Et itaconate) in the presence of alc. NaOEt to give *Et δ -cyanobutane- α,β -dicarboxylate*, b₁ 170° , and in the presence of a suspension of Na in C_6H_6 to give *Et γ -cyano- β -methylpropane- α,β,γ -tricarboxylate*, b₁ 190° (corresponding acid, m. 164° ; cf. Perkin and Thorpe, *J. Chem. Soc.* 75, 52 (1899)). Et fumarate and $\text{NCCH}_2\text{CO}_2\text{Et}$ condense under the latter conditions to yield *Et γ -cyanopropane- α,β,γ -tricarboxylate*, b₁ 167° , and γ -*cyano- α,β -carbethoxypropane- γ -carboxylic acid* (decomps. to Et γ -cyanopropane- α,β -dicarboxylate, b. 282° , on heating (cf. Thorpe *J. Chem. Soc.* 77, 923 (1900))).

B. C. A.

Considerations relative to a critical study by F. P. Mazza (rotatory dispersion of

alkyl aspartates). M. L. PAGLIARULO. *Atti accad. Lincei* [6], 7, 577-9(1928).—An answer to a recent paper by Mazza (cf. *C. A.* 21, 1798; 22, 1957). Reasons are given to show that the methods employed and the results obtained by P. are reliable.

C. C. DAVIS

Condensation of glucosamine hydrochloride with ammonium thiocyanate. K. ISHIFUKU. *J. Pharm. Soc. Japan* 48, No. 6, 584-6(1928).—Pauly and Ludwig (*C. A.* 16, 4211) obtained thiolglucimidazole (I) $C_7H_{12}O_4N_2S \cdot H_2O$ (decomps. 168°) by condensing glucosamine-HCl (II) with KCNS. By repeating the above reaction I. obtained a compd. (III), $C_7H_{12}O_4N_2S$, decomps. 210° , which on removal of S with H_2O_2 gave glucimidazole (HCl salt, m. 162°), showing that III is I without H_2O of crystn. II and NH_4CNS also gave a good yield of III.

NAO UYET

The synthesis of sucrose. KURT P. JACOBSON. *Naturwissenschaften* 16, 529-30 (1928).—A short sketch of the recent synthesis of sucrose by Pictet and Vogel (*C. A.* 22, 2743). Several references are given.

B. J. C. VAN DER HOEVEN

Cyclopropane derivatives. P. BRUYLANTS AND A. DEWAELE. *Bull. Sci. Acad. Roy. Belg.* [v], 14, 140-53(1928).—When cyclopropyldimethylcarbonil is treated with HCl and the product distd. several times there is obtained α -chloro- δ -methyl- γ -pentene, b. $132-3^\circ$, d_4^{20} 0.92653, n_D^{20} 1.44193, which is converted by prolonged treatment with KOAc and a small quantity of AcOH into the corresponding acetate, b. $170-1^\circ$, d_4^{20} 0.9108, n_D^{20} 1.43107. Hydrolysis of this gives δ -methyl- γ -penten- α -ol, b_{717} 157° , d_4^{20} 0.85765, n_D^{20} 1.44564, identical with the methyl pentenol prep'd. by Van Aerde (*C. A.* 3, 2700). The product of the reaction of HBr and cyclopropyldimethylcarbonil, (cf. *C. A.* 3, 2700), when treated with NaOEt gives α -ethoxy- δ -methyl- γ -pentene, b. $142-3^\circ$, d_4^{20} 0.7989, n_D^{20} 1.41948, also obtained from the above Cl compd. HCl converts the ethoxypentene into δ -chloro- α -ethoxy- δ -methylpentane, b_{737} $172-3^\circ$, d^{20} 0.9094, which is decompd. by boiling water in presence of $CaCO_3$ yielding α -ethoxy- δ -methylpentan- δ -ol, b. $182-3^\circ$ (*C. A.* 21, 731). Prolonged treatment of α -chloro- δ -methyl- γ -pentene with boiling water in presence of $CaCO_3$ and further treatment with alc. KOAc and a little NaI regenerates mainly cyclopropyldimethylcarbinol. An explanation of the change is suggested.

B. C. A.

Oxidation in the benzene series by gaseous oxygen. IV. Mechanism of the slow oxidation of saturated hydrocarbons. H. N. STEPHENS. Univ. of Minnesota. *J. Am. Chem. Soc.* 50, 2523-9(1928); cf. *C. A.* 22, 406.—A new mechanism of the oxidation of satd. hydrocarbons by gaseous O is proposed, which accounts for the inhibitory action of H_2O in the oxidations studied: Hydrocarbon + $O_2 \rightleftharpoons$ complex $\rightleftharpoons H_2O$ + unsatd. residue \rightarrow aldehyde or ketone. The oxidation of a hydrocarbon to aldehyde or ketone does not go through the alc. stage. Oxidation of PhMe and PhEt was carried out in the presence of Ac_2O in an attempt to get an ester of the intermediate alc. but in neither case was any ester detected. The oxidation of xylol acetate with O gives no toluic aldehyde. By using equimol. amts of PhEt and PhMeCHOH, a much greater yield of BzMe is obtained in a given time from the hydrocarbon than from the alc.

C. J. WESR

Diazo compounds. A. ANGELI. *Atti accad. Lincei* [6], 7, 699-705(1928).—A critical review and discussion of the behavior of diazo compds. As in a previous communication on the same subject (cf. *C. A.* 20, 2991), the reactions of these compds. is explained without resort to stereoisomerism, which always leads to contradictions. Diazohydroxides formed by reduction of nitroamines and isonitroamines. According to Hantzsch and Reddelien (*Die Diazoverbindungen*, 2nd Ed. Berlin, 1921, 43), isodiazotates are formed by the reduction of isonitroamine salts, while under similar conditions diazotates are formed from nitroamine salts. This would be at variance with all known facts, and both normal and isonitroamines would be expected to form the same reduction product: $PhN \cdot N(OH)O \rightarrow PhN:NOH \leftarrow PhN(O):NOH$, and in fact Bamberger (cf. *Ber.* 27, 1181(1894); 30, 1249(1897); *C. A.* 15, 1516) has reduced both normal and isonitroamines to isodiazotates. Other instances, partly from expts. of A., are cited to show that the information of Hantzsch is erroneous. Coupling of some diazobenzene derivs.—According to Hantzsch (*loc. cit.*, p. 57), diazo ethers formed from alcs. and normal diazotates ($PhN:NOEt$ is also formed by the action of alc. KOH on *anti*-phenylazoxycarboxamide—[private communication from E. Bamberger]) are *anti*-derivs., and during sapon. form transiently an amine and alkyl nitrite. Various reasons are given to show that this explanation is not plausible and that publications of A. are sufficient to explain the sapon. and coupling reactions of diazo compds. Thermochemistry of diazo compds.—The assertion of H. and R. (*loc. cit.*) that normal diazo derivs. have a greater energy content is contrary to expts. by Swientoslawski (cf. *Bull.*

acad. polonaise sci. 1924, 369), and the isomerization of diazonium hydroxides to isodiazohydroxides is an endothermic reaction, not an exothermic reaction. *Stereoisomerism of diazohydroxides and of benzaldoximes*—Finally the assertion of H. and R. that normal diazo compds. and their isomers differ in virtue of stereoisomerism is readily disproved by exptl. data already published by various authors, enough examples of which are given to show the error of the assertion of H. and R. *Oxidation of diazotates*.—Diazotates are not, as maintained by H. and R. (*loc. cit.*, p. 37), more easily oxidized than isodiazotates to nitroamines, and publications of A. (*Die Azoxyverbindungen*, Stuttgart, 1913, 30) and of Bamberger (*Ber.* 27, 915(1894); *C. A.* 4, 183) are sufficient to show that the reactions are essentially different. C. C. DAVIS

Large-scale alkaline fusion of salts of sulfo acids. V. V. MASLENNIKOV. *J. Chem. Ind. (Moscow)* 5, 77-8(1928).—Alk. fusion of Na sulfonates is usually carried out on a large scale by gradually adding the dissolved salt and slowly raising the temp. As, however, the aq. sulfonates do not react with NaOH under the usual conditions, much more time is required for evapn. of the water than for the reaction. For this reason, and also for the purpose of increasing the yields, M., operating with PhSO_3Na , modified the method as follows. NaOH is melted and, at 295° , 600-650 kg. of 50% sulfonate at $95-98^\circ$ is introduced in the course of 5-7 min., whereupon the temp. drops to $250-240^\circ$. After 35-40 min. the temp. again rises to 300° , whereupon a new quantity of sulfonate is introduced, which causes a new drop of temp., and so on. It is established that the max. utilization of the sulfonate is attained if the max. temps. (*i. e.*, just before each consecutive addn.) are resp., 295° , 300° , 305° , 310° , and the min. temps. (after each consecutive addn.), are from 240° to 270° . Towards the end of the operation the temp. is gradually raised to 340° in order to correct the possible defects of the fusion, since the most favorable temp. of reaction is not known. By using this method the % of utilization of the sulfonate is raised to 90-95%, and even to the theoretical, against 54-60% attained by the old method; the time required for the reaction was reduced to 6 hrs. BERNARD NELSON

Action of sodium peroxide on phenol. Preparation of pyrocatechol and hydroquinone. O. YU. MAGIDSON, E. YA. POROZOVSKA AND N. E. SELIGSOHN. *Trans. Sci. Chem. Pharm. Inst. (Moscow)* No. 6, 23-5(1923).— Na_2O_2 is added in small quantities, with cooling and stirring, to a soln. of phenol in H_2SO_4 ; the mixt. is kept for 12 hrs. and then heated at $50-60^\circ$. After sepn. of resinous substances, pyrocatechol (25% of the total yield) and hydroquinone (25%) remain. B. C. A.

Relation between the chemical constitution and pungency. Syntheses of ethyl hydroferulate and 4-hydroxy-3-methoxyphenylpropyl alcohol. HIROSHI NOMURA AND SEINOSUKE HOTTA. *Sci. Repts. Tôhoku Imp. Univ.* 1st ser. 17, 693-4(1928).—*Hydroferulic acid* was esterified by heating with abs. alc. and a little H_2SO_4 to give *Et hydroferulate*, b_{17} $192.5-3.0^\circ$, with a pungent taste similar to zingerone. Reduction of the ester with abs. alc. and Na gave *4-hydroxy-3-methoxyphenylpropyl alc.*, b_{16} 196° , with a pungent taste not as agreeable as zingerone. T. S. CARSWELL

Relation between the chemical constitution and pungency. EITARO MARUI. *Sci. Repts. Tôhoku Imp. Univ.* 1st ser. 17, 695-702(1928).—*o-Hydroxystyryl Et ketone* (I), m. $116-8^\circ$, was prepd. by shaking $o\text{-HOC}_6\text{H}_4\text{CHO}$ with MeCOEt and aq. NaOH. Reduction of I with Na-Hg yielded *o-hydroxyphenylethyl Et ketone* (II), m. 72° . *o-Hydroxystyryl Ph ketone* (III), m. $153-4^\circ$, was prepd. by shaking $o\text{-HOC}_6\text{H}_4\text{CHO}$ with PhCOEt and aq. NaOH. Reduction of II with H in the presence of Pt black gave *o-hydroxyphenylethyl Ph ketone* (IV), m. 91° . Reduction of $o\text{-HOC}_6\text{H}_4\text{CH:CHCOMe}$ with Na-Hg gave *o-hydroxyphenylethyl Me ketone* (V), m. $47-8^\circ$, $b_{15.5}$ 139° . Reduction of V with Zn and HCl gave *o-hydroxyphenylbutane* (V), b_{11} $101-2^\circ$. *o-Hydroxycinnamic acid*, from coumarin and EtONa , was reduced with Na-Hg to *hydro-o-coumaric acid* (VII), m. $82-3^\circ$. The following salts of VII were prepd. and identified: $\text{ANa} \cdot \text{H}_2\text{O}$; $\text{AK} \cdot \text{H}_2\text{O}$; A_2Ca . Distn. of VII under 769 mm. gave *hydrocoumarin*, b_{185} $270-2^\circ$. Esterification of VII yielded *Et hydro-o-coumarate* (VIII), b_{185} $272-3^\circ$. The action of concd. NH_4OH on either hydrocoumarin or VIII gave *hydro-o-coumaramide*, m. $91-2^\circ$. II was pungent and had a paralyzing action, while IV was at first sweet, with a gradual development of pungency. VI was pungent although it does not contain a CO_2H group. Of the salts of VII, the Na and K salts were pungent, and the Ca salt, less sol. than the other, was less pungent. The anhydride, Et ester and amide of VII were pungent. T. S. CARSWELL

Electrolytic reduction of aldehydes. II. *m*-Nitrobenzaldehyde. G. SHIMA. *Mem. Coll. Sci. Kyôto Imp. Univ.* 11, [A], 1-10(1928).—The effect of variations in c. d., temp. and acidity on the reduction of $m\text{-O}_2\text{NC}_6\text{H}_4\text{CHO}$ to *m*-aminobenzyl alc. has been studied. In aq. alc. contg. 10% of H_2SO_4 a yield of more than 90% is

obtained by using 5 amp. per sq. dm. with a Pb cathode at 25–35°. With a Cu cathode, reduction soon ceases and the product contains mainly the hydrobenzoin, $[H_2NC_6H_4CH:NC_6H_4CH(OH)]_2$, with small quantities of *m*-azoxybenzaldehyde and *m*-amino-benzyl alc. (cf. Gattermann, *Ber.* 29, 3037–40, 3040–2(1896); Löb, *Ber.* 31, 2201–5 (1898)).

Syntheses of 4-hydroxy-3-methoxystyryl propyl and amyl ketones. SHUNJI TSURUMI, SHUNICHI MURAKOSHI AND RICHIRO YAMASAKI. *Sci. Repts. Tōhoku Imp. Univ.* 1st ser. 17, 703–5(1928).—Vanillin (I) and MeCOPr were condensed by boiling with aq. KOH to 4-hydroxy-3-methoxystyryl *Pr ketone*, m. 82–3°. Reduction of the ketone with H_2O and Na–Hg gave 4-hydroxy-3-methoxyphenylethyl *Pr ketone*, m. 44.5–5.0°. In a similar manner, I was condensed with MeCOAm to yield 4-hydroxy-3-methoxystyryl *Am ketone*, m. 50.0–0.5°, $b_{1.5}$ 208–10°, and giving on reduction 4-hydroxy-3-methoxyphenylethyl *Am ketone*, m. 38.0–8.5°, b_3 177–8°.

Syntheses of 4-hydroxy-3-methoxyphenylethyl pentenyl and hexenyl ketones. HIROSHI NOMURA AND SAM EL. CHOI. *Sci. Repts. Tōhoku Imp. Univ.* 1st ser. 17, 707–10(1928).—PrCHO was added to a soln. of zingerone in aq. KOH, when 4-hydroxy-3-methoxyphenylethyl pentenyl ketone (I), $b_{4.5}$ 198.5–200°, was obtained. Reduction of I with H in the presence of Pt black, followed by benzoylation, gave 4-benzoyloxy-3-methoxyphenylethyl *Am ketone*, m. 78.5–9.5°. BuCHO (II) was prepd. by passing a mixt. of $BuCO_2H$ and HCO_2H (1:2 by vol.) over MnO at 340–60°. It was then condensed with zingerone in alk. soln., when 4-hydroxy-3-methoxyphenylethyl hexenyl ketone (III), b_3 193–4°, was obtained. Reduction and benzoylation of III gave 4-benzoyloxy-3-methoxyphenylethyl hexyl ketone, m. 74.5–5.0°.

Catalytic reduction of the nucleus of aromatic and fatty-aromatic aldehydes in the form of their acetals. I. (Hexahydrophenylacetaldehyde dimethyl acetal.) FRITZ SIGMUND. *Univ. Wien. Monatsh.* 49, 271–82(1928).— $PhCH_2CH(OEt)_2$ did not give definite results but the reduction of $PhCH_2CH(OMe)_2$ in AcOH gives 81% of hexahydrophenylacetaldehyde *di-Me acetal*, b. 204.5–6°. The aldehyde, b. 179–81.5°; semicarbazone, m. 162°.

Action of sodium benzyl cyanide with cinnamic ester. II. S. AVERY. *Univ. of Nebraska. J. Am. Chem. Soc.* 50, 2512–9(1928); cf. C. A. 2, 1829.—Na (5 g.) in MeOH, 25.5 g. $PhCH_2CN$ and 35.7 g. $PhCH_2CHCO_2Me$ at 0° for 5 hrs. and at 20–5° for several days give 67% of *Me β, γ-diphenyl-γ-cyanobutyrate*, m. 106.5° (all m. ps. cor.); this ester also results from the acid and MeOH with HCl; *Et ester*, m. 101.5° (50% yield). Sapon. with EtOH–KOH gives the free acid (90% yield). Boiling the acid or esters with strong KOH gives *β, γ-diphenyl-γ-glutaramide*, $C_{17}H_{17}O_3N$, m. 200–5° (decompn.). Acid hydrolysis gives *α, β-diphenylglutaric acid*. Na (3 g.) as NaOEt, nearly free from EtOH, 7.5 g. $PhCH_2CN$ and 22.5 g. $PhCH_2CHCO_2Et$, heated in 75 cc. $PhMe$ for 3 hrs., give 13 g. *Et 2-keto-4,5,6-triphenyl-5-cyanohexahydrobenzoate*, m. 208–9°; this also results by heating the above mixt., without $PhMe$, at 100° (50% yield) or by heating *Et β, γ, δ-triphenyl-γ-cyanopimelate* with EtONa. The *Me ester* m. 242–4°. Sapon. of the esters gives *β, γ, δ-triphenyl-γ-cyanopimelic acid*, m. 218–9°; *Me ester*, m. 108.2°; *Et ester*, m. 102.5°. The supposed "anhydride" previously reported is the above keto acid.

Addition reactions of unsaturated α-ketonic acids. II. MARIE REIMER AND MARION HOWARD. *Barnard College. J. Am. Chem. Soc.* 50, 2506–12(1928); cf. C. A. 20, 3164.—For the purpose of comparison with other unsatd. α-ketonic acids, *o*-methoxybenzalpyruvic acid (I) and its reactions with Br have been studied. While I and its *Me ester* (II) combine readily with Br, in all other respects the properties have been changed to a marked degree as compared with the unsubstituted acid and the *p*-MeO deriv. Condensation of $MeCOCO_2H$ and *o*- $MeOC_6H_4CHO$ in 10% NaOH gives 80% of I, brilliant red-orange, m. 131°; on exposure to bright sunlight, the color soon fades noticeably. II, bright yellow, m. 48°; exposure to moist air in the dark brings about hydrolysis; on exposure to bright light, II liquefies in a few min. because of admixture with light products. The *Et ester* is a bright yellow oil, b_{15} 223°. I and Br in $CHCl_3$ give the dibromide, straw-colored, m. about 90° (vigorous decompn.); warming in C_6H_6 , boiling with H_2O or warming on the H_2O bath gives *β-bromo-o-methoxybenzalpyruvic acid* (III), m. 173°; oxidation gives $MeOC_6H_4CH:CBrcO_2H$, m. 171°; benzalpyruvic acid (IV), m. 88–9°. The action of Br upon II gives III and IV. I, with an excess of Br, gives 5-bromo-*o*-methoxybenzalpyruvic acid dibromide, m. 95–100° (not pure); *Me ester*, m. 103–6° (not pure); the acid is transformed by boiling 40% AcOH into *β-bromo-5-bromo-2-methoxybenzalpyruvic acid* (IV), colorless, m. 210° (decompn.) (*Me ester*, m. 131°). When the *Me ester* of the tri-Br deriv. is stirred with 2% MeOK in MeOH, a yellow isomer of IV, m. 210°, results; on heating, the yellow color fades

at 145–50° and the colorless product, m. 210° (*Me ester*, pale yellow, m. 143°). With Br in MeOH there was no addn. of MeOBr. The color reactions of H₂SO₄ with ketonic acids are tabulated.

C. J. Wessr

Synthesis of isomers of piperic acid. HERMANN LOHAUS. Univ. Münster. *J. prakt. Chem.* 119, 235–71 (1928).—The Mg compd. from CH₃O₂:C₆H₅C:CH and EtMgBr gives with HC(OEt)₃ 30% of *methylenedioxyphenylpropargylaldehyde di-Et acetal*, b₁₈ 188–90°; sapon. with very dil. H₂SO₄ gives 31% of the *aldehyde*, m. 76°, also obtained in about the same yields from the above Mg compd. and HCO₂Et. CH₂O₂:C₆H₅C:CH in liquid NH₃ reacts with Na but the resulting Na compd. does not react with HCO₂Et. The acetal and CH₂(CO₂H)₂ in AcOH give up to 82% of *piperonylpropargylenemalonic acid*, m. 250° (decompn.); from C₆H₅N the acid crystals, as a *di-C₆H₅N salt*, yellow, decomp. 231°; from the HCl soln., there crystallize a light yellow compd., C₁₈H₁₅O₅N, decomp. 204°, and an isomeric yellow compd., decomp. 237°. CH₂O₂:C₆H₅CH:CHCHO, b₁₋₂ 175–90°, m. 84–5°, results in 29% yield according to the method given; *piperonylenemalonic acid*, m. 231–2°, results in 94% yield; the C₆H₅N salt, yellow, decomp. 191–2°. Heating the acid with quinoline at 140° gives 52% *isopiperic acid*, m. 149°. Reduction of PhC CCH(OEt)₂ with Pd and charcoal gives a product b₁₈ 125–42°, consisting principally of PhCH:CHCH(OEt)₂, identified by conversion into *trans-cinnamylidenemalonic acid*, decomp. 195–6°. Reduction of the aldehyde gives only *trans-PhCH:CHCHO*. *Piperonylpropargylaldehyde* gives a mixt. of unchanged aldehyde and the dihydro deriv. *Piperonylacrolein* gives *piperonylpropane*. Reduction of *phenylpropargylenemalonic acid* in MeOH gave only an oil; in AcOH, there results *cinnamylidenemalonic acid*, in another expt., *trans-cinnamylidenemalonic acid*; reduction of the C₆H₅N salt in C₆H₅N gives the *cis-cinnamylidenemalonic acid*; reduction of the acid with BaSO₄-Pd also gives the *cis-acid*. Reduction of the Na salt of *piperonylpropargylenemalonic acid* gives *γ,δ-dihydro-piperonylenemalonic acid*, yellow, m. 173°. Reduction of the piperidine salt gives *cis-piperonylenemalonic acid*, m. 117–9° (decompn.); quinoline apparently splits off all the CO₂ from this acid, as indifferent products result.

C. J. Wessr

Transformation of aliphatic terpenes into monocyclic terpenes. A. **Synthesis of menthol.** RIKI HORIUCHI. Takasago Perfumery Co. *Mem. Coll. Sci. Kyoto Imp. Univ., Series A* 11, No 3 (reprint), 171–97 (1928).—*Citronellal* (I), isolated from Java citronella oil and purified by NaHSO₃ followed by distn., b₂₀ 97–8°, d₄²⁰ 0.8563, n_D²⁰ 1.4490, [α]_D + 10° 9'. Treatment of I with 5% H₂SO₄ at 25–30°, followed by fractionation of the crude product, yielded *isopulegol* (II), *menthoglycol* (III) and an *unsatd. ethereal compd.*, which after reduction with H in AcOH gave a product with d₄²⁰ 0.9180 and n_D²⁰ 1.4640. Treatment of I with 20% H₂SO₄ yielded II, III and an *ethereal compd.* (IV), b₁₈ 191.5°, d₄²⁰ 0.9341, n_D²⁰ 1.4760, [α]_D –5° 30', with an empirical formula corresponding to C₁₀H₁₈O₂ or C₁₀H₁₆O₂. Reduction of IV yielded a *hydrogenated compd.* C₁₀H₁₈O₂, d₄²⁰ 0.9155, n_D²⁰ 1.4635, [α]_D –2° 52'. Treatment of I with 50% H₂SO₄ gave a *new hydrocarbon*, C₁₀H₁₆, called *citronellal-terpene* (VI), d₄²⁰ 0.8535, n_D²⁵ 1.4875; it formed neither a hydrochloride nor a nitroschloride; and an *ethereal compd.* C₁₀H₁₆O₂. When I was heated to 140° with KHSO₄, a violent reaction took place with the formation of II and *diisopulegol ether*, C₂₀H₃₄O, d₄²⁰ 0.9120, n_D²⁰ 1.4835, [α]_D 12° 15'. Treatment of I with Ac₂O yielded *isopulegol acetate*, *enol monoacetate* and *diacetate of citronellal*. *Citral* (V) obtained from East Indian lemon-grass oil b₁₇ 112–5–5.0°, d₄²⁰ 0.8886, n_D²⁰ 1.4901, [α]_D 0° 10'. Treatment of V with 20% H₂SO₄ gave a *new terpene*, C₁₀H₁₆, named *citral-terpene*, b. 183–6°, d₄²⁰ 0.8886, n_D²⁰ 1.5092, together with unstable unsatd. compds. By the action of 50% H₂SO₄ V was converted to *p-cymene* and resinous substances of unknown compn. KHSO₄ and V at 140° yielded *p-cymene* and a *di-terpene*, C₂₀H₃₄, b₁₄ 190–4°, d₄²⁰ 0.9244, n_D²⁰ 1.5280. Ac₂O did not act on V at 20°, but at 150° reaction took place, yielding *enol citral acetate* together with unidentified substances. AcOH and V gave mostly *p-cymene*. When II is treated with 20% H₂SO₄, some III is formed; when 50% H₂SO₄ is used, there is obtained an *ethereal substance* and a *terpene* identical with VI. The action of KHSO₄ on II forms *diisopulegol ether*. III, b₁₈ 141–6°, d₄²⁰ 0.9806, n_D²⁰ 1.4730, [α]_D 6° 31', was mostly unchanged when treated with 20% H₂SO₄; 50% acid transformed it partly to VI; KHSO₄ gave VI and *diisopulegol ether*. III was reduced by H in AcOH, with Pt black as a catalyst; from the crude reduction product *l-menthol*, m. 33–4°, [α]_D –44.92° as was isolated; the latter on oxidation yielded *l-menthone*, m. 114–6°, [α]_D 58.77°. T. S. C.

The possible isomers of certain analogs of resolvable diphenyl compounds. J. F.

HYDE AND ROGER ADAMS. Univ. of Illinois. *J. Am. Chem. Soc.* **50**, 2499–506 (1928).—A configuration in which the 2 aromatic nuclei are coaxial and not in the same plane apparently accounts for all of the known facts concerning the optical activity in certain Ph₂ compds. It is generally accepted that the asymmetry arises from the influence which the groups located in the *o*-position to the connecting bond have in preventing free rotation of the 2 nuclei. If the prevention of free rotation is entirely a matter of the space occupied by interfering groups and does not require a direct association of 2 aromatic rings, then it should be possible to resolve compds. of the type 2,6-XY-C₆H₃COR and 2,6,3-X₂YC₆H₂COR, which could become asymmetric by reason of steric hindrance; however, no optically active compds. could be obtained by decompn. of salts with active compds. Bromomesitylene and BzCl with AlCl₃ in CS₂ give 92% of *benzoylbromomesitylene*, b₁₂, 173–5°, m. 48–9°; this did not react with BrCH₂CO₂Et and Zn or with PhMgBr; oxidation gives a neutral, viscous liquid *p*-Nitrobenzoylbromomesitylene, light yellow, m. 1.4–5° (85% yield); the 3,5-di-NO₂ deriv., light yellow, m. 160–1.5°, was obtained in 24% yield. Catalytic reduction gives *p*-aminobenzoylbromomesitylene, m. 138°; HCl salt, needles. If the reduction is carried out in AcOEt instead of EtOH, some *aro* compd., C₁₆H₁₁ONBr, red, m. 203–5°, is also formed. 3,5-Diamino deriv., yellowish brown, m. 168–9°. Fractionation of the *d*-camphorsulfonate of either amino deriv. gave no indication of resolution. Similarly, fractionation of the brucine salts of 2-carbisopropoxy-3-nitrobenzoic acid and of 2-[2-hydroxy-4-methylbenzoyl]-3-nitrobenzoic acid gave no indication of resolution. The optical behavior of the *d*-camphorsulfonates in CHCl₃ is described; the change in rotation upon standing is due to a change in the character of the mol. either by tautomerism or by combination with the solvent; the change is not permanent and is not characteristic of the base used.

C. J. WEST

Configuration of *o*-substituted benzophenone oximes. JAKOB MEISENHEIMER, RUDOLF HANSSEN AND ALFRED WICHTEROWITZ. Univ. Tübingen. *J. prakt. Chem.* **119**, 315–67 (1928).—2,4-Me₂C₆H₃OMe (100 g.) and 110 g. BzCl in 200 cc. CS₂, gradually added to 150 g. AlCl₃ in 200 g. CS₂, give 105 g. (60%) of crude 3-methoxy-4,6-dimethylbenzophenone (I), and about 8% of the 3-HO deriv., m. 140–1°. I in petroleum ether, shaken with Claisen's liquor and then distd., gives the pale yellow oil, b₁₁, 199–200°. With NH₂OH HCl in KOH-EtOH, I gives a mixt. of the α -oxime (II), b₁₀, 218°, m. 138–9°, and about 2% of the β -oxime, m. 119–20°; the difference in soly. of the 2 oximes is very slight, so that the sepn. is difficult. Attempts to transform II into the β -isomer failed. II is unchanged after long boiling with AcOH, after warming with dil. or concd. HCl or dil. H₂SO₄ at 100° or after standing 36 hrs. in concd. H₂SO₄. The Bz deriv. of II m. 135–6°. The Beckmann rearrangement of II with PCl₅ in Et₂O gives 3-methoxy-4,6-dimethylbenzanilide, m. 141–2°, whose constitution was established by sapon. to 3-hydroxy-4,6-dimethylbenzoic acid, m. 185–6°. The Beckmann rearrangement of the β -oxime gives *N*-benzoyl-3-methoxy-4,6-dimethylbenzaniline (III), m. 153–4°, which was synthesized as given below. The isomeric 2-methoxy-3,5-dimethylbenzaniline benzoate m. 48–9°. 3-Ethoxy-4,6-dimethylbenzophenone, b₁₀, 190–1° (35% yield); α -oxime, m. 148–9°; β -oxime, m. 133–4° (very small yield of the latter); the Beckmann rearrangement of the α -oxime gives 3-ethoxy-4,6-dimethylbenzanilide, m. 150–7°. I with HI in AcOH gives the 3-IIO deriv., m. 140–1°, probably identical with the product obtained by Linari (*Gazz. chim. ital.* **33**, II, 60 (1903)); the oxime, m. 182–3°, does not give well defined products with PCl₅, but with AcOH and Ac₂O there results *N*-benzoyl-3-acetoxy-4,6-dimethylbenzaniline, m. 127–8°; hydrolysis gives the 3-HO deriv. (IV), m. 173–4°, and a small quantity of 3-hydroxy-4,6-dimethylbenzanilide, m. 211–2°; methylation of IV gives III. With concd. HCl at 150–60°, IV gives 2,4,5-Me₃(HO)C₆H₂NH₂, m. 162–3°. 2-Hydroxy-3,5-dimethylbenzophenone oxime, m. 153–4°; with PCl₅ this yields 2-phenyl-5,7-dimethylbenzoxazole, m. 99–100°. 2-Bromo-2',4'-dichlorobenzophenone, b₁₀, 227–8.5°, m. 33–4°, results in 43% yield from *m*-C₆H₄Cl₂ and *o*-BrC₆H₄COCl with AlCl₃ in CS₂; an oxime could not be obtained in the usual ways; in alk. soln. there results a mixt. of a compd., m. 158–60°, which appears to be a chlorobromohydroxybenzophenone, and 3-[2,4-dichlorophenyl]indoxazene, m. 78°. 2-Bromo-5-nitro-2'-hydroxy-5'-methylbenzophenone (V), m. 151–2° (65% yield); with EtOH-NaOH, this yields 2-methyl-7-nitroxanthone, m. 224°, which gives with MeOH-KOH a compd., m. 146–8°, probably 2,2'-dihydroxy-5-nitro-5'-methylbenzophenone. Heating V with NH₂OH.HCl in EtOH at 120–5° gives the oxime, pale yellow, m. 218°; with EtOH-NaOH this gives a compd. C₁₄H₁₀O₂N₂, m. 148°, which is either an indoxazene or a xanthone deriv.; PCl₅ gives an uncrystallizable oil. 2-Bromo-2'-hydroxy-5'-methylbenzophenone (VI), pale yellow, m. 78.5° (80% yield); EtOH-NaOH gives the yellow Na salt; 30% MeOH-KOH gives 2-methyl-

xanthone, m. 125.5°. The oxime of VI, pale yellow, m. 144.5°. 2-Bromo-2'-methoxy-5'-methylbenzophenone, m. 50-1° (43% yield); the oxime, m. 193°, undergoes a Beckmann rearrangement, giving the *o*-bromobenzoyl deriv. of 2-methoxy-5-methylaniline, m. 130-1°; with MeOH-KOH the oxime gives quant. 3-[2-methoxy-5-methylphenyl]indoxazene, b_{0.5} 170°, golden yellow oil.

C. J. WESS

Two high-molecular hydrocarbons, derivatives of fluorene and methane. K. DZIEWONSKI AND M. PANEK. *Bull. intern. acad. Polonaise* 1927, 745-51.—Methylal (I) and fluorene in CHCl₃ in the presence of P₂O₅ give a new hydrocarbon, C₂₇H₂₀, 2,2'-difluorylmethane (II), m. 201-2°. Oxidation of II with Na₂Cr₂O₇ in AcOH gives 2,2'-difluorenone ketone (III), m. 297-8°, which with PhNHNH₂ gives a trisphenylhydrazone, m. 203° (decompn.). Fusion of III with KOH at 250-60° gives 2,4'-diphenyl-dicarboxylic acid, m. 244-7°. In addn. to I, by the further action of I on II, a bisdifluorylenemethylenemethane (IV), m. 246-7°, is formed. Oxidation of IV gives a deriv. contg. five CO groups, m. 324-6°, which by fusion with alkali gives an acid, m. 235-7°.

FREDERICK C. HAHN

Complex isomerism and complex-salt isomerism. EDUARD HERTEL AND JAKOB VAN CLEEF. *Univ. Bonn. Ber.* 61B, 1545-9 (1928).—The complex isomeric system 2,6-dinitrophenol-1,4-bromonaphthylamine exists in 2 forms, a yellow compd. (m. 91.5°) and a red compd. (m. 84.5°). These are examd. by means of x-rays, and are found to possess large differences in the arrangement of the interference rings in the Debye-Scherrer diagrams. This type of isomerism is exhibited by a series of systems between polynitrophenols and primary aromatic amines. The system *N*-dimethyl-β-naphthylamine-2,4,6-trinitroanisole can be crystd. from abs. alc. in the form of dark red needles (m. 69°), which are given the formula MeOC₆H₂(NO₂)₃—C₁₀H₇N(Me)₂. If this compd. is heated above 77°, it becomes yellow, the m. p. is now 190°, and it is found to be identical with trimethyl-β-naphthylammonium picrate, (NO₂)₃C₆H₂ON(C₁₀H₇)Me₃. This is representative of the type complex-salt isomerism, in which 1 isomer is a true mol. compd. and the other a quaternary NH₄ salt. The principal distinction between the 2 types of isomerism lies in the fact that the yellow isomer of the 1st type is partly dissociated into its components in fusion and soln., equil. being established between the 2 isomers and their components, while the yellow isomer of the complex salt isomeric system is not decompd. in soln. Phase diagrams of the 2 types of systems are given.

H. STOERTZ

Oxidation of anthracene by nitrogen oxides. M. A. IL'INSKI, B. V. MAKOROV AND N. V. ELAGIN. *J. Chem. Ind. (Moscow)* 5, 469-73 (1928).—The authors undertook to investigate whether crude 45-50% anthracene can, instead of the pure product, be used with advantage as material for mfg. anthraquinone by oxidation with N oxides. In carrying out these expts. they had in view anthraquinone prepn. by the method of Ger. pat. 268,049, May 3, 1909 (*Friedl.* 11, 541); the reactions were in 2 stages and PhNO₂ was used as a solvent. NaNO₂ was used as a source of N oxides which, being obtained by adding H₂SO₄ drop by drop, were mixed with some air and passed, by means of slight suction, through the reaction mixt. At first the action of N oxides mixed with air on nitrobenzene was investigated by operating with freshly distd. and dried PhNO₂. The absorption of the gases was very slow at room temp., only reaching 10-15% in 3 days, but by cooling with snow and salt, it was easy to have 25% (and more) of N oxides absorbed. There was no chem. action. In the 2nd place, by operating with a soln. of 25 g. of pure anthraquinone in 100 g. of PhNO₂ it was established that the N oxides had no action on anthraquinone. To study the action of N oxides mixed with air on pure synthetic anthracene 100 g. PhNO₂ was satd. with these gases with cooling till it increased in wt. 40 g. and in vol. by 1/4 and then 25 g. of the finely triturated pure anthracene was introduced in small portions. Each portion dissolved with heat formation which was counteracted by cooling. The dark green mass was left standing several days, at the end of which it became light green; its wt. was 165 g. The mass was heated over a water bath for elimination of N oxides. On cooling, a yellow cryst. powder of anthraquinone pptd., which was freed from PhNO₂ by steam and dried; it weighed 17 g. The PhNO₂ obtained by steam distn. of the mother liquors weighed 96 g. and left in the flask a residue of anthraquinone, which, after crystn. from glacial AcOH, weighed 12 g. Thus 29 g. of pure anthraquinone was obtained instead of the theoretical yield of 29.2 g.; the transformation may be regarded as quant. For the detn. of the action of N oxides on 2-methylantraquinone 15 g. of the latter (m. 175°) was dissolved in 60 g. of PhNO₂, satd. with the gases with cooling till the soln. weighed 90 g., heated 5 hrs. on a water bath and analyzed. It was found that 2-methylantraquinone is not affected; it followed that, with anthracene contg. 2-methylantraquinone as an impurity, the latter must be obtained as a

product contaminating anthraquinone. Operating with a suspension of 32 g. of *carbazole*, m. 236°, in 128 g. PhNO_2 , the authors established that N oxides transform carbazole successively into 9-nitroso-, 3-nitroso-, 3-nitro-, 9-nitroso-3-nitro-, 3-nitro-6-nitroso-, and 3,6-dinitrocarbazole; the last named is the final and main product of reaction. By passing N oxides into a soln. of 30 g. *phenanthrene* in 120 g. PhNO_2 the authors obtained resinous products of the oxidation of phenanthrene. After these preliminary expts. the authors subjected to the action of N oxides a PhNO_2 soln. of a very impure anthracene contg. but 5.5% of anthracene. They found that all the products of oxidation dissolved in the PhNO_2 together with the resins and the tars; the fraction containing anthraquinone did not sep. from the rest. The next expt. was with a 50% anthracene. Out of 100 g. of the latter, which theoretically corresponds to 58 g. anthraquinone, 55 g. of solid product sep'd. which contained 25.2 g. anthraquinone. The results obtained with 25.65% and 41.9% anthracene showed that anthraquinone as well as N and S compds. became distributed in all fractions. With an 87% anthracene anthraquinone of 97-93% purity was obtained with a yield of 80% of the theoretical. The next series of expts was devoted to the investigation of the possibility of sepg. anthraquinone from the other products of oxidation of impure anthracene by means of conc'd. H_2SO_4 ; they obtained very unsatisfactory results and concluded that the H_2SO_4 method of purification of anthraquinone is not suitable in case the latter was obtained from very impure anthracene. Attempts to obtain pure anthraquinone by partial reduction of the products of N oxides reacting with impure anthracene also gave negative results, the agents tried being on one hand alk. $\text{Na}_2\text{S}_2\text{O}_4$, on the other hand alkali hydroxide and Zn powder.

Rubrene. Colored hydrocarbons of the rubrene class. CHARLES MOUREU, CHARLES DUFRAISE and ANTOINE WILLEMART. *Compt. rend.* 187, 266(1928); cf. C. A. 22, 2748.—Two new homologs of rubrene have been isolated. *dimethylrubrene*, m. 315°, from $p\text{-MeC}_6\text{H}_4\text{C}:\text{CH}$ and Ph_2CO , and *dibenzorubrene*, m. 280°, from $\beta\text{-C}_6\text{H}_5\text{C}:\text{CH}$ and Ph_2CO . D. H. POWERS

Anthraquinone solutions in sulfuric acid. P. I. SOKOLOV AND V. P. DREYING Aniltrust Factory. *J. Chem. Ind. (Moscow)* 5, 412-6(1928).—The detn. of the soly. of anthraquinone in H_2SO_4 of various concns. and the conditions of its pptn. from these solns. have a practical interest, in as much as crude anthraquinone is usually treated with H_2SO_4 for purification. As a result of S. and D.'s study of this problem they believe they have considerably improved the industrial method of anthraquinone purification by H_2SO_4 . The method is founded on the belief that, when crude anthraquinone is heated with H_2SO_4 , it dissolves without chem. alteration, whereas the hydrocarbons which contaminate it become sulfonated and partly resinified; the soln., on being dild. with water, ppts. pure anthraquinone. *Solubilities of anthraquinone* of 99.25% purity in H_2SO_4 of various concns. were detd. by Rothmund's method (cf. C. A. 2, 2476), i. e., by noting the temps. of satn. as indicated by appearance of turbidity on cooling, after which the results obtained were verified by another method; it was found that both methods give the same results. These detns. were made with H_2SO_4 of concns. ranging from 82.5 to 99.7% and at temps. varying from 26° to 135°; tables contg. the soly. figures and diagrams consist^g of soly. curves are given. The soly. increases with the temp. at all concns. of the acid, but the increase is greater for higher concns. than for lower. The curves representing the isotherms of soly. show the dependence of the soly. on the concn. of the acid; all these isotherms have a marked upturn beginning with the point corresponding to a H_2SO_4 concn. of about 88%. A series of expts. were made to det. whether pure anthraquinone is chem. affected by conc'd. H_2SO_4 ; the results show that on heating anthraquinone for 6 hrs. at 115-25° with twice its wt. of 99.7% H_2SO_4 about 12% of the former is destroyed, whereas on treating anthraquinone under the same conditions with 4 times its wt. of 93.3% H_2SO_4 the loss of anthraquinone is only 0.025%. The appearance of anthraquinone samples obtained in both cases is not the same, the sample which was heated with 99.7% H_2SO_4 was darker than that heated at the same temp. with 93.3% H_2SO_4 . The study of conditions of pptn. of anthraquinone dissolved in H_2SO_4 is particularly important, in as much as an incorrect dildn. of the soln. is apt to yield a finely cryst. compact prodn. which can hardly be filtered and washed. By merely dildg. the soln. with cold water, and particularly by pouring the soln. into water, anthraquinone is always obtained in a non-filterable form. Proper crystals must be of larger size, and such a crystn. can only be had by gradual cooling of solus. In dealing with anthraquinone solns. in 93.3% H_2SO_4 , S. and D. recommend to allow them to cool slowly to about 30°, whereupon a portion of anthraquinone (about 14 g. per 100 g. of the acid) ppts. in fairly large crystals. At this temp. the soln. contg. the ppt. is dild. with a quantity

of water sufficient to reduce the concn. of the acid to 90%; a cryst. powder ppts. which is redissolved by heating to 110°, whereas the larger crystals obtained in the course of the first pptn. remain undissolved. On letting this dild. soln. cool off gradually to 30° a new pptn. of larger crystals takes place. Then the mixt. is dild. with water till a concn. of 87% H₂SO₄ is attained, the pptd. cryst. powder is redissolved by heating and repptd. in fairly large crystals on gradual cooling. Finally the concn. of H₂SO₄ is reduced to 80%, the mixt. is heated to dissolve the small crystals formed and allowed to cool in order to ppt. larger crystals. Since the soly. of anthraquinone in 80% H₂SO₄ at ordinary temp. is insignificant, all the anthraquinone is pptd. at this stage. Filtration and thorough washing of this ppt. obtained by fractional crystn. presents no difficulty.

BERNARD NELSON

Bitertiary glycols and some of their heterocyclic derivatives. E. PACE. Univ. Pisa. *Atti accad. Lincei* [6], 7, 757-64 (1928).—The ready formation of heterocyclic compds. from compds. contg. COH groups sepd. by 2 other C atoms in a chain (cf. Paal, *Ber.* 18, 58, 397, 2251) suggested a study of bitertiary γ -glycols to det. whether tetrahydrofurfurans, tetrahydropyrroles and tetrahydrothiophenes could be obtained in the same way. This was rendered very probable by the transformation of γ -diketones in their enolic form into furfuran, pyrrole and thiophene derivs. The bitertiary γ -glycols were prepd. by the action of MeMgBr, EtMgBr or PrMgBr on AcCH₂CH₂Ac (cf. *Ber.* 35, 2138 (1902); *Bull. soc. chim.* 1902, 1138; Jöhlén, *C. A.* 11, 590). The tetrahydrofurfurans were formed by keeping the glycols in vacuo over H₂SO₄, or by heating the glycols in AcOH for 2 hrs. at 120–50° in the presence of H₂SO₄, or better ZnCl₂, and extn. with Et₂O. The yields are 70–75%. The tetrahydropyrroles were obtained by heating the glycols with a slight excess of concd. alc. NH₃ under pressure at 150° for 2 hrs., evapg. the NH₃ and EtOH and fractionating. The yields are 60–80%. If the heating is more than 2 hrs., secondary reactions form unsatd. resinous products, while less than 2 hrs. results in smaller yields. From AcCH₂CH₂Ac the following compds. were prepd.: 2,5-dimethylhexane-2,5-diol, Me₂C(OH)CH₂CH₂C(OH)Me₂, m. 92–3°, slight camphor odor, its C₆H₁₄ solns. show a greenish fluorescence; 2,5-diethylhexane-2,5-diol, slightly colored, b. 172–3°, characteristic camphor odor, its concd. C₆H₆ soln. shows a slight greenish transitory fluorescence; 2,5-dipropylhexane-2,5-diol, golden yellow, b. 198–200°, characteristic pleasant odor. By the methods described were prepd. the following furfuran compds. and pyrrole derivs. Tetrahydrofurfurans: α, α_1 -Tetramethyl, Me₂C.CH₂.CH₂.CMe₂.O, b. 119.5°, characteristic odor,

similar to the compd. called diisocrotyl oxide by Pogorzelsky (*J. Russ. Phys.-Chem. Soc.* 30, 977–92 (1899)); α, α_1 -dimethyl- α, α_1 -diethyl, MeEtC.CH₂.CH₂.CMeEt.O, b. 165°,

characteristic odor; α, α_1 -dimethyl- α, α_1 -dipropyl, b. 186°, characteristic odor, becomes yellow and changes its odor when exposed to air. All 3 tetrahydrofurfurans give the reaction of furan derivs., coloring a pine splinter wet with HCl an emerald-green, reacting neither with Na nor with alkalis and not being decompd. by steam. Tetrahydropyrroles: α, α_1 -tetramethyl, Me₂C.CH₂.CH₂.CMe₂.NH, pale rose color, b. 108° (cf. Pauly and

Hültenschmidt, *Ber.* 36, 3357), gives a red test with a pine splinter and a green-blue in an isatin-H₂SO₄ soln.; α, α_1 -dimethyl- α, α_1 -diethyl, very mobile, pale rose color, b. 125°, turns brown rapidly when exposed to air, gives the pine-splinter but not the isatin-H₂SO₄ test; α, α_1 -dimethyl- α, α_1 -dipropyl, very mobile, red, b. 147–9°, turns brown rapidly in air, turns a pine splinter bright red, evolves H with Na.

C. C. DAVIS

Stereoisomerism of 8-hydroxydecahydroquinoline and its derivatives. SHIN-ICHIRO FUJISE. *Sci. Papers, Inst. Phys. Chem. Research* 8, 161–71 (1928).—The hydrogenation of 8-hydroxyquinoline (I) in AcOH, with Pt-black as a catalyst, gives 10% of decahydroquinoline (II) and a mixt. of two stereoisomers (A and B) of 8-hydroxydecahydroquinoline (III). A as isolated by crystn. of the base from petroleum ether, m. 111–2°, b₂₀ 136–46°; HCl salt, m. 201–2°; HBr salt, m. 202–3°; chloroaurate, m. 191–2°; d-bromocamphorsulfonate, m. 250–3°. The 8-Bs deriv. of A, prepd. by the Schotten-Baumann reaction and crystd. from aq. acetone, m. 130–1°; the HCl salt m. 255–6°. N-O-Di-Bs deriv. of A, prepd. by treating A with an excess of BzCl and pyridine, m. 81–3°. B, m. 92–3°, is obtained by crystn. of its HBr salt, m. 251°, from abs. alc.; HCl salt, m. 247–8°; chloroaurate, m. 188–9°. The 8-Bs deriv. of B, m. 93–5°; HCl salt, m. 251°. A or B, when converted to the alcoholate by Na, heated to 140°, and treated with HCl, gives another isomer (C) of III, m. 101–2°; HCl salt (IV) of C m. 245–6°; chloroaurate, m. 152–3°. The 8-Bs deriv. of C, m. 99–100°; HCl salt, de-

comps. 302°. *N-O-Di-Bz* deriv. of *C*, obtained as with *A*, m. 92–3°. *N-Me* deriv. of *C* (*V*), prep'd. by treating *IV* with 40% CH_3O at 130–40°, b. 125–6°; *picrate* m. 123–4°; *MeI addn. compd.*, m. 285–6° (gas evolution). The *8-benzoyl-N-methyl* deriv. of *C*, obtained by treating *V* with Bz_2O and then crystg. from petroleum ether, m. 91–2°; *chloroplatinate*, m. 231°; *picrate*, m. 193–5°. *C* treated with Me_2SO_4 and alkali, followed by treatment with *KI*, gives the corresponding *quinolinium iodide*, m. 285–6°, but none of the corresponding *MeO* deriv.; *picrate* of the quaternary base, m. 173–4°. The *d-bromocamphorsulfonate* (*VI*) of the *d*-form of *C* m. 294 5°, $[\alpha]_D^{25}$ 84.9°. The impure free base obtained from *VI* shows $[\alpha]_D^{23}$ 47.6°; *HBr salt* m. 213–4°, $[\alpha]_D^{25}$ 29.6°. The corresponding *sulfonate* of the *l*-form of *C* m. 262–3°, $[\alpha]_D^{23}$ 41.8°; impure, free base, $[\alpha]_D^{25}$ —53.1°; *HBr salt*, m. 211–3°, $[\alpha]_D^{23}$ —31.6°. Catalytic hydrogenation of *quinoline* (*VII*) with Pt-black gives *II*, m. 48–48.5°, b. 201°; *HBr salt*, m. 277–9°; *chloroaurate*, m. 124–5°; *chloroplatinate*, m. 228° (decompn.); and also a liquid *isomer* of *II*, whose *N-Bz* deriv. m. 96–7°. The *N-Bz* deriv. (*VIII*) of *II* m. 53–4°. Oxidation of *VIII* with KMnO_4 gives *o-benzoylamino-hexahydrophenylpropionic acid* (*IX*), m. 199–200°, which on warming with concd. HCl gives octahydrocarbostyryl, m. 152–3°. Hydrogenation of *VII* by the Sabatier method gives 80% of *II*, m. 48–48.5°, and on oxidation material (*X*) (purified by crystn. of the *HBr salt*, m. 232°) that is a *stereoisomer* of *II*, b. 205–6°, b_{19-21} 89–91°, d_4^{20} 0.9426, n_D^{20} 1.4926, *HCl salt*, m. 223–4°; *chloroaurate* m. 157–8°; *picrate*, m. 135–6°. The *N-Bz* deriv. of *X* m. 96–7°, and on oxidation with KMnO_4 gives an acid, *IX*, m. 156–7°. As to the explanation of the foregoing isomerism, *F.* believes *A* and *B* to be *cis*-forms, but reserves further comments on this for a future publication.

FREDERICK C. HAHN

Oxidation of bromoquinolines by potassium permanganate. T. UKAI AND H. AKIYA. Kumamoto Pharm. Coll. Japan. *J. Pharm. Soc. Japan* 48, No. 6, 587–90 (1928).—Oxidation of 6-bromo- (*I*), 8-bromo-, 5-bromo-8-methyl- and 7-bromo-8-methylquinolines with alk. KMnO_4 resulted in the rupture of the C_6H_4 ring and gave quinolinic acid (*II*) in every case. Brominated compds. were more resistant to oxidation than non-brominated compds. and took longer time for complete reaction. Besides *II*, *I* gave a non-N acid (does not m. 300°).

NAO UYEI

Pyocyanin, the blue pigment of *Bacillus pyocyaneus*. III. The constitution of hemipyocyanin. FRITZ WREDE AND E. STRACK. Univ. Greifswald. *Z. physiol. Chem.* 177, 177–86 (1928); cf. *C. A.* 19, 1864.—Hemipyocyanin, obtained from the bacterial pigment pyocyanin, has now been prep'd. in greater purity by repeated sublimation and found to have the formula $\text{C}_{12}\text{H}_8\text{N}_2\text{O}$ instead of $\text{C}_{13}\text{H}_{12}\text{N}_2\text{O}$ as previously reported. It has both acidic and basic properties, forms a *Me* deriv. indicating the presence of OH , also a *N(O)* deriv. and yields phenazine almost quant. when dist'd. with Zn dust. The cleavage of pyocyanin by 2% NaOH in the absence of air yields not only hemipyocyanin but also a leuco base of pyocyanin from which the pigment is regenerated by exposure to air. The same leuco base is obtained by reduction of the pigment with Na-Hg in acid or alk. soln., and oxidized back to the pigment by shaking the alk. soln. with air. The formula $\text{C}_{12}\text{H}_8\text{N}_2\text{O}$ corresponds to an α - or a β -hydroxyphenazine. The β -deriv. is known and m. 253°, whereas hemipyocyanin m. 158°. The α -deriv. has now been prep'd. and found to be identical with hemipyocyanin. 2,3-(HO) $_2\text{C}_6\text{H}_3\text{OMe}$ was oxidized in C_6H_6 by means of PbO_2 to the *o*-quinone, and the latter condensed with *o*- $\text{C}_6\text{H}_4(\text{NH}_2)_2$ in AcOH . The product was isolated by extn. of the reaction mixt. with NaOH , the C_6H_6 layer with 15% HCl , making alk., the HCl ext. and shaking with Et_2O . Evapn. of the Et_2O gave α -methoxyphenazine, yellow, m. 169°, identical with the *Me* deriv. of hemipyocyanin as shown by mixed m. p. Hydrolysis of this by heating 5 hrs. at 100° with fuming HBr converted it into α -hydroxyphenazine (*I*), m. 158°, identical with hemipyocyanin. Attempts to prep. *I* by diazotization of α -aminophenazine were unsuccessful.

A. W. DOX

Dyes derived from quinoline-2,3,4-tricarboxylic acid. J. D. TEWARI AND S. DUTT. *J. Indian Chem. Soc.* 5, 59–62 (1928); cf. *C. A.* 21, 3194.—Quinoline-2,3,4-tricarboxylic acid condenses with phenols either alone or in the presence of SnCl_4 or H_2SO_4 to give the following dyes of the *phthalein* type: *phenol*, m. above 280°; *resorcinol*, m. 194° (yellowish green fluorescence); *phloroglucinol*, m. above 280°; *pyrocatechol*, m. above 280°; *m-diethylaminophenol*, m. 220° (brown fluorescence); *m-phenylgallol*, m. above 280°; *m-dimethylaminophenol*, m. above 280° (green fluorescence). The *enediaminequinoline-2,3,4-tricarboxylein*, m. above 280° (green fluorescence). The dyes are probably produced by condensation of the phenol with the O atom of the 3-C in the intermediate anhydride.

BOORD, CECIL ERNEST: **Laboratory Outlines for Premedical Organic Chemistry.** Revised. Columbus, Ohio: The Ohio State Univ. Press. 51 pp.

Stibonic acids. FITZGERALD DUNNING and EBENEZER E. REIB (to Hyson, Westcott & Dunning). U. S. 1,682,269, Aug. 28. Stibanic acid, in good yield, is obtained by diazotizing a soln. of acetyl-*p*-phenylenediamine and Sb_2O_3 in HCl and decomg. the resulting diazo Sb compd. in a hot caustic alkali soln. $PhSbO_3H_2$ and other similar stibonic acids may be similarly prepd.

Alkyl esters of abietic acid. ALAN C. JOHNSTON (to Hercules Powder Co.). U. S. 1,682,280, Aug. 28. Wood rosin is treated with Et_2SO_4 , Me_2SO_4 or other alkyl sulfate in the presence of an alkali such as NaOH.

Hydroxy acid esters. HOWARD W. MATHESON and KENNETH G. BLAIR (to Canadian Electric Products Co.). U. S. 1,682,347, Aug. 28. See Brit. 264,143 (C. A. 22, 91).

Oxamic acid halides. I. G. FARBENIND. A-G. Brit. 282,801, Sept. 30, 1926. Phenylloxamic acid chloride is made by the action of oxalyl chloride on aniline-HCl. β -Naphthylloxamic acid chloride is made by the action of oxalyl chloride on β -naphthylamine-HCl. α -Tolylloxamic acid chloride and α -naphthylloxamic acid chloride can be similarly prepd. by gentle heating. An excess of oxalyl halide and an inert diluent may be used.

Butyric acid and its homologs. JACQUES LEFRANC (to Soc. des brevets etrangers Lefranc & Cie.). U. S. 1,683,198, Sept. 4. See Brit. 276,617 (C. A. 22, 2378).

Producing sebacic acid salts or other soluble salts of organic compounds of acid character. MAX BUCHNER (to Albert F. Meyerhofer). U. S. 1,683,159, Sept. 4. An insol. metal salt of the substance is first formed, e. g., by use of hydroxides of Ca, Mg, Pb or Zn, and this insol. compd. is then treated with a fluoride such as NaF, the base of which forms a sol. org. compd. with the original material.

Acetic anhydride. HENRY DREYFUS. Fr. 634,167, May 11, 1927. See C. A. 22, 3417.

Separation of amines. BRITISH DYESTUFFS CORP., LIMITED, ERNEST HARRY RODD and REGINALD WILLIAM EVERATT. Fr. 634,905, May 24, 1927. See Brit. 270,930 (C. A. 22, 1594).

Organic bases by catalytic treatment of acetylene and ammonia. I. G. FARBENIND. A-G. Brit. 283,163, Jan. 5, 1927. Org. bases such as diethylamine, triethylamine, α - and γ -methylpyridine and higher methylpyridines and polynuclear bases are produced by passing a mixt. of C_2H_2 and NH_3 over catalysts such as may be prepd. by soaking pumice, asbestos or coke (dried at 500-600°) in a soln. of an anhyd. halide such as $ZnCl_2$, a mixt. of $ZnCl_2$ and $FeCl_3$ or a mixt. of $CdCl_2$ and $CuCl_2$. The reaction is effected at 280-350° but is exothermic and therefore an inert gas is advantageously admixed with the reactive gases.

Alkali metal alcoholates of compounds containing alcoholic hydroxyl groups. CHRISTIAAN VAN LOON. U. S. 1,681,600, Aug. 21. In prepg. alkali metal alcoholates of glycol (mono- or di-Na glycolates) or other non-sugar-contg. compds. contg. 2 or more alc. OH groups, a soln. of the latter compd. in an aq. soln. of an alkali metal hydroxide is dehydrated by heating to a max. temp. between 50° and 350° (suitably about 110-115° with glycol in a current of H under reduced pressure) but lower than the temp. at which deterioration begins and sufficiently high to expel all water.

Aminophenol ethers. J. TCHERNIAC. Brit. 282,907, Oct. 2, 1926. *o*-Anisidine is made by stirring methylsalicylamide with an aq. soln. of NaOCl and NaOH and heating to boiling. Other aminophenol ethers may be similarly prepd.

Carbazides and thiocarbazides. BRITISH DYESTUFFS CORP., LIMITED, GEORGE MALCOLM DYSON, FREDERICK ALFRED MASON and ARNOLD RENSCHAW. Fr. 634,908, May 24, 1927. $COCl$ or $CSCl$ is caused to react on hydrazines having the formula $P-NH-X-Q-NH-Y-R-NH-NH_2$, P denoting a sulfonated naphthyl or an acenaphthyl

group, Q and R the aryl, aralkyl or alkylene derivs of the same groups and X and Y each denoting either a carbonyl or sulfonyl group.

Acetal. SOC. ANON DES DISTILLERIES DES DEUX SEVRES. Brit. 283,112, Jan. 3, 1927. Alc. and AcH are treated with a catalyst such as HCl, H₂SO₄, toluenesulfonic acid, HOAc, PH₃ or CaCl₂ or other suitable metal salts, in only about 0.1-0.2 the quantity of the catalyst previously ordinarily used. Various details are given and an app. is described.

Butyrene. HENRI DOLTER. Fr. 634,959, Sept. 23, 1926. See Brit. 277,975 (C. A. 22, 2573).

Dioxan. ANGELO KNORR and GERHARD STEIMMIG (to I. G. Farbenind. A.-G.). U. S. 1,681,861, Aug. 21. Dioxan is made in a continuous operation by heating glycol in the presence of a catalyst such as H₂SO₄, benzenesulfonic acid, H₃PO₄ or ZnCl₂ and adding glycol to the boiling mixt. in the same quantity as dioxan distils off. As starting materials there may also be used ethers derived from glycol such as dihydroxy-diethyl oxide and dihydroxydiethyl oxide monoethyl ether.

Erythrene. ALEXANDER T. MAXIMOFF (to Naugatuck Chemical Co.). U. S. 1,682,919, Sept. 4. An aliphatic aldehyde such as crotonaldehyde or aldol (mixed with alc. and water) contg. at least 4 C atoms is pyrogenetically decompd. by heating at temps. below 500° to produce a mixt. of erythrene and other products and the erythrene is recovered, e. g., by use of Br to form erythrene bromide.

Methanol synthesis. HENRY H. STORCH (to Roessler & Hasslachner Chem. Co.). U. S. 1,681,750, Aug. 21. A mixt. of H and CO is passed over a heated catalyst comprising Cu obtained from a cuprammonium compd., e. g., by boiling the latter with NaOH and reducing with H. U. S. 1,681,751 specifies synthesis of MeOH from H and CO by use of a catalyst comprising Cu and fluoride of Ca, Ba, Sr or Mg. U. S. 1,681,752 specifies a catalyst comprising Cu formed by the reduction of CuO pptd. from a cuprammonium salt soln. in intimate mixt. with Mg(OH)₂. U. S. 1,681,753 specifies a catalyst comprising Pd and Cr₂O₃, ZnO or Ce₂O₃.

Synthetic methanol. COMMERCIAL SOLVENTS CORP. Fr. 635,023, May 25, 1927. A catalyst for the prepn. of MeOH from H and oxides of C comprises one or more difficultly reducible metallic oxides such as the oxides of Zn, Mg, Cd, Cr, V, W, with one or more easily reducible metallic oxides such as the oxides of Fe, Ni, Co, Cu and a metallic halide such as ZnCl₂, MgCl₂, CrCl₃, MgBr₂, ZnBr₂. The difficultly reducible oxides are preferably predominant. Cf. C. A. 22, 2756.

Methylene chloride. I. G. FARBENIND. A.-G. Brit. 283,119, Jan. 3, 1927. A mixt. of Cl and an excess of MeCl may be passed through a tube heated to 300-380° and the reaction may be assisted by use of catalysts, light or pressure.

Quinaldines. BRITISH DYE-STUFFS CORP., LIMITED AND MAX WYLER. Fr. 634,782, May 21, 1927. See Brit. 276,156 (C. A. 22, 2379).

Thiuram monosulfides. ALEXANDER T. MAXIMOFF (to Naugatuck Chemical Co.). U. S. 1,682,920, Sept. 4. In prepg. a thiuram monosulfide from the corresponding disulfide the latter is treated, while in suspension in water or other non-solvent, with NaCN or other suitable metallic cyanide in aq. soln.

Polymerized styrene. IVAN I. OSTROMUISLENSKII and MORRIS G. SHEPARD (to Naugatuck Chemical Co.). U. S. 1,683,401, Sept. 4. Unpolymerized styrene is combined with a non-homogeneous tough transparent polymerized styrene and polymerization is effected to a tough transparent modification, e. g., by heating at 180° for 3 hrs. Cf. C. A. 22, 3171.

Polymerized styrene. IVAN I. OSTROMUISLENSKII (to Naugatuck Chemical Co.). U. S. 1,683,402, Sept. 4. In forming α -m-styrenes styrenes of approx. 92% purity or higher are heated to 140-175° for 3-20 hrs. (the higher the temp. the shorter the time of heating). U. S. 1,683,403 specifies forming β -m-styrene by heating styrene of about 92% or higher purity in a substantially horizontal tube in an air bath at about 140° for approx. 40 hrs. U. S. 1,683,404 specifies making γ -m-styrene by treating styrene with a peroxide, e. g., benzoyl peroxides at 175-180° for 1-1.5 hrs. U. S. 1,683,405 specifies producing vitreous polymerized styrenes from crude petroleum oil by cracking the crude oil vapors at a temp. of about 650° and collecting the condensable portion of the product thus formed, heating the styrenes in the fraction to form brittle, impure resinous polymerized styrene, heating the resinous product to obtain styrene of greater purity, and repolymerizing the styrene to produce tough vitreous polymerized styrene.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

Soluble dehydrogenases. T. THUNBERG. *XII Int. Cong. Physiol.* 1926, 161.—Seeds are ground with 5 parts of 0.5 *N* K_2HPO_4 soln., and the mixt. is centrifuged and filtered; the filtrate is colloidal and macroscopically homogeneous. Various specific donors are described. B. C. A.

The coagulation of fibrin as a process of micellary crystallization and of agglutination. E. HEKMA. *Nederland. Tijdschr. Geneeskunde* 72, 1, 2792-800, 2888-93 and 3670-77(1928).—A summarizing review. H. holds that the substance pptd. from fibrinogen solns. is not always fibrin, but in certain cases, unchanged fibrinogen, as e. g., if a pptn. occurs following the addn. of salts, acids or alkali, or by stirring or by contact with glass. In these cases, the ppt. can be redissolved; it is, moreover, softer than true fibrin which is formed chiefly by thrombin, as H. holds. The pptd. fibrinogen has a different microscopic aspect from fibrin, as it tends to form needles owing to a so-called micellary crystn., while thrombin causes agglutination. The decompn. of blood platelets is supposed to cause coagulation by diminishing the alky. and by the taking up of water. R. BEUTNER

The resistance of insulin to treatment with radium and x-rays. D. DEN HOGD AND S. E. DE JONGH. *Nederland. Tijdschr. Geneeskunde* 72, 1, 3169-73(1928).—In the absence of air, insulin is resistant to Ra and x-rays. In the presence of air, Ra causes a slight decompn., while x-rays are without effect. R. BEUTNER

Variation of p_H of equilibrated solutions as the result of the action of the regulatory power of the tissues. M. COMEL. *Atti accad. Lincei* [6], 7, 772-8(1928); cf. C. A. 21, 3940.—The p_H values of mixts. composed of phosphate equilibrating solns. and muscle and frog liver broths were detd. Jarisch phosphate solns. were used in different combinations to obtain the different p_H values. The results, recorded in tables and graphs, show the notable influence of the regulatory system of the tissues on the p_H of the phosphate solns. The relation between the resultant p_H (y) values and the p_H (x) values of the soln. is: $y = a + bx$, a straight line. The p_H value of the broth soln. when the p_H of the soln. is 0 is represented by a . The results show that a is 4.92 and b is 0.28. When the p_H values of the soln. and the broth are equal, $y = x$. Further analytical deductions, in which it is shown how to det. the equilibrating power of the tissue relative to the phosphate solns., indicate that tissues possess a regulatory system which opposes any variation in their p_H value induced by other regulatory systems of different p_H value. It is therefore possible to det. electrometrically the p_H value of a tissue broth, the value being detd. by the point at which there is no change in the p_H value of an equilibrating soln. in which the tissue is suspended. C. C. D.

The aluminum content of human autopsy tissue. V. C. MYERS AND J. W. MULL. Western Reserve Univ., Cleveland. *J. Biol. Chem.* 78, 625-6(1928).—The av. Al content of human visceral organs ranged from 0.07 to 0.25 mg. per 100 g. A. G.

Cholesterol and lipid phosphorus in infancy and in childhood: Normal incidence in cord blood and during infancy and early childhood. MURRAY B. GORDON AND DAVID J. COHN. *Am. J. Diseases Children* 35, 193-200(1928).—Blood serum from the umbilical cord at birth contains 89 mg. per 100 cc. cholesterol and 4.1 mg. per 100 cc. lipid P. Blood serum in the first week of life contains approx. the same concns. The cholesterol content, which is 136 mg. per 100 cc. at the end of the 1st year, increases gradually to a concn. of 169 mg. per 100 cc. in the 6th year. The lipid P content increases rapidly during the 1st year. At the end of the 1st year, it has a value of 5.8-6.1 mg. per 100 cc. It remains const. during the next 4 years and reaches a concn. of 7.8 mg. per 100 cc. in the 6th year. E. R. MAIN

The normal cerebrospinal fluid in children. DONALD STEWART. *Arch. Disease Childhood* 3, 96-108(1928).—The protein content of normal cerebrospinal fluid in children has the value of 15-55 mg. per 100 cc. for the lumbar region, 12-50 mg. per 100 cc. for the cisterna magna and 5-18 mg. per 100 cc. for the lateral ventricles. It does not vary with increasing age. The chloride content is 630-760 mg. per 100 cc. for the 3 regions. The sugar content is detd. by the concn. of sugar in the blood and is 45-66% of the latter value. The cell count, which is normally 20-30 per cu. mm. in infants, decreases gradually as age increases and becomes identical with that of adults

at 10–12 years. Measurements of pressure give unreliable results because of difficulties in obtaining manometric readings on children.

Potash in the animal body. J. ULRICH DUERST. Zoötechnischen Inst. d. Univ. Bern. *Ernähr. Pflanze* 24, 267–73(1928).—An address.

The sense of taste. A. CAPPUYNS. *Bull. trimestr. assocn. élèves école sup. brasserie univ. Louvain* 28, 80–6(1928).—A brief review of recent work on the chemistry of taste.

Electrolysis of partitioned neutral saline solutions. Modifications of p_H at the surface of the septum. M. CHANOT. *Compt. rend. soc. biol.* 99, 513–5(1928); cf. *C. A.* 22, 1170, 1787.—During the electrolysis of a dil. neutral soln. enclosed by a membrane giving negative osmosis, there is produced at the same time at each face of the membrane an inverse modification of the saline concn. and p_H of the soln. The saline concn. diminishes and the p_H increases at the face of the + pole, but the saline concn. increases and the p_H diminishes at the face of the – pole of the source of electricity.

Probable amount of ultra-violet radiation obtained indoors through ultra-violet transmitting glass. JANET HOWELL CLARK. *Science* 68, 165–6(1928).—It was estd. that a person would receive as much ultra-violet radiation in 2 min. in direct sunlight at noon, as in an entire day behind a window of ultra-violet transmitting glass.

The peptidases. HANS VON EULER AND ZOLTÁN I. KERTÉZ. *Ber.* 61B, 1525–9(1928).—In consequence of the hypothesis of Euler and Josephson (*C. A.* 21, 2278) that the attack of the peptidases from the type of the intestine crepsin starts with a primary addn. of the amino group of the substrate on the carbonyl group of the enzyme, the question was investigated whether the group attached to the amino group of the peptide has the nature of a carbonyl group of a simple sugar. Glycerol ext. from pig intestine furnished the enzyme material. As substrates were chosen glycylglycine and α -alanylglycine. To 5 cc. of 0.25 *N* peptide soln. were added 2.0 cc. glycerol ext. and enough 0.1 *N* NaOH to give a p_H of 8.0; then an inhibiting substance was added and the vol. made up to 25 cc. The reaction velocity was detd. and compared with that of an equiv. peptide soln. not contg. the inhibiting compd. The expts. were carried out at 37°. The method of Willstätter and Waldschmidt-Leitz (cf. *C. A.* 16, 944) was used to exam. the progress of the cleavage. In the expts. with glycylglycine, the 0.001 *N* solns. of the sulfates of quinine and quinidine, which are only slightly sol. in H_2O , had little effect on the reaction velocity on account of the small concn. in which the alkaloids were present. Alc. solns. of the alkaloids could not be used, because EtOH had a strong inhibitory action on the cleavage process. $PhNH_2$, glycine and particularly boric acid had a pronounced inhibitory effect. NH_3 had no influence. With glycine ester no distinct results were obtained, because the lipase present in the enzyme prepn. caused partial sapon. of the ester. The cleavage velocity of glycylglycine was greater than that of α -alanylglycine. Addn. of glycine had a slightly smaller inhibitory effect on the cleavage of α -alanylglycine than that of α -alanine had.

Dependence of catalytic and oxidative effects of iron on its state of adsorption. RICHARD KUHN AND ALBERT WASSERMANN. *Ber.* 61B, 1550–67(1928); cf. *C. A.* 17, 2718.—The changes in the catalytic and oxidative activity of hemin brought about by adsorption on different adsorbents are studied. The catalytic properties of $FeCl_3$ in soln. are compared with those of Fe in an adsorbed and an “embedded” state. The rate of H_2O_2 decompn. and O_2 -transmission on linseed oil was detd. by gas analysis, the former reaction being checked at the same time by titration with 0.1 *N* $KMnO_4$. The app. used for the hemin expts. contained in the main vessel hemin and adsorbent suspended in phosphate buffer soln. The H_2O_2 or the linseed oil was placed in a side tube. A special bulb contained KOH, absorbing any CO_2 eventually developing. The expts. were carried out under artificial light and with rotation (130 r. p. m.). The temp. was kept const. within $\pm 0.3^\circ$. Examn. of different adsorbents showed that charcoal, alumina and metastannic acid were best suited for the purpose, since under the exptl. conditions, no hemin was lost from the adsorbents. Hemin solns. contg. 1 mg. α -chlorohemin in 1 cc. 0.02 *N* Na_2HPO_4 were used for the catalase expts.; for the oxidase expts. also a soln. in 2.5% pyridine was employed. In the catalase expts., only the β -activity (cf. *C. A.* 18, 613) was measured. The values thus obtained for the amt. of O_2 liberated by 1 mg. hemin in 60 min. out of 69 cc. of 0.019 *N* H_2O_2 soln. at a p_H of about 5 were as follows: in soln.: 3000 cc. (16° , 722 mm.); on charcoal: 8400 cc. (16° , 725 mm.); on metastannic acid: 3000 cc. (15° , 722 mm.); on alumina: strong inhibition. In the oxidase expts., after eliminating the values obtained in the first 5–8 min., 1 mg. hemin transferred in 120 min. on 0.32 cc. of a 0.5% linseed oil sus-

pension at a p_{H} of about 6.3 following amts. of O_2 : in soln.: 210 cc. (16° , 722 mm.); on 0.2 g. metastannic acid: 210 cc. (16° , 720 mm.); on 0.24 g. alumina: 120 cc. (16° , 723 mm.); on 0.2 g. charcoal: 80 cc. (17° , 720 mm.). Leucine was not oxidized in the presence of hemin, hemin-alumina and hemin-metastannic acid. With hemin-charcoal, the O_2 transmission was the same as with charcoal alone. Fructose absorbed a small quantity of O_2 when shaken in phosphate soln. Addn. of charcoal, alumina and metastannic acid, and further addn. of hemin had no influence on the reaction velocity. The oxidation of dihydroxyacetone in phosphate soln. (cf. *C. A.* 20, 1637) is not accelerated by hemin. Further addn. of charcoal or alumina was without effect, while metastannic acid tended to retard the reaction. The expts. with FeCl_3 as a catalyst were carried out similarly to the catalase expts. Adsorption on charcoal increased the activity of FeCl_3 in decomp. H_2O_2 considerably, compared with that of FeCl_3 in soln. Metastannic acid and particularly alumina had a retarding effect. When in the charcoal- FeCl_3 system the H_2O_2 was replaced by water, the ferrous ion was extd., as proven by the color reaction obtained with $\text{K}_3\text{Fe}(\text{CN})_6$. From this observation, K. and W. conclude that the reduction of ferric to ferrous ion at the boundary surface of the phases is responsible for the activation of the H_2O_2 catalysis observed after adsorption of FeCl_3 on coal.

G. SCHWOCH

Fate of acetylcholine in the blood. III. Effect of surface area on the degree of splitting. YAMIKO KODERA. Univ. Innsbruck. *Arch. ges. Physiol.* (Pflüger's) 219, 181-9(1928).—The degree of acetylcholine splitting to take place in the blood increases logarithmically as the no. of red blood cells is increased. When the no. of red cells is kept const. the splitting becomes greater or less as the cells are caused to swell or to shrink through changing the tonicity of the medium. Whether these changes are due solely to quant. relations, or whether qual. factors in the surface also contribute is not known.

G. H. S.

Osmotic concentration of the secretions. J. STRAUB AND L. SOEP. *Arch. néerland. physiol.* 12, 346-67(1928).—A series of analyses of secretions and sera before and after dialysis are given. The secretions are all negative colloids. The Donnan equil. was manifested in all of the expts.

M. H. SOULE

The swelling of biocolloids. I. Ultra-violet rays and swelling of agar-agar. JAN CALÁBEK. Masaryk Univ., Brno, Czechoslovakia. *Protoplasma* 3, 17-42(1927).—Ordinary marketable agar was dissolved in boiling H_2O and poured on a glass-plate slightly coated with vaseline. It dried into a thin sheet out of which square disks of 25 mm. were cut. The expts. with disks were carried on in series. In each series disks of the same age and the same thickness were used, the thickness of the disks were as follows 0.02, 0.04, 0.083, 0.095, 0.12 mm. The dry disks were illuminated either by "Höhensonne" or natural sun rays at intervals of 1, 3, 9, 27, 81 and 146 min. After that they were allowed to swell on auxographs of the MacDouglas type, modified by Úlehla. Out of the auxograms obtained from one and the same series a family of curves was derived, e. g., on the X-axis was plotted the time of swelling in hrs. against the degree of swelling expressed as the percentage of the dry thickness on the Y-axis. The swelling velocity of non-illuminated agar-disks is the quicker the thinner they are, but the max. of their swelling capacity is the higher the thicker they are. The difference in the swelling max. is rather small (3030% with agar-disks of 0.02 mm. thickness, against 3370% with agar-disks of 0.12 mm. thickness). "Höhensonne" as well as natural sun rays lower the swelling capacity of agar to a large extent, depending on the length of time the agar has been illuminated. The max. decrease of the swelling capacity was achieved with "Höhensonne" after an illumination of 146 min. on one side of the agar-disk, the swelling reaching but 1525% in this case against 3200% achieved by non-illuminated agar. The action of ultra-violet rays causing this decrease of the swelling capacity is practically limited to the extreme layers of the gel, decreasing in the depth very rapidly so that their effect practically ceases at 0.08 mm. below the surface. This influence can be preserved in dry agar-gel for several months and even if dry agar be dissolved and dried again it appears to be partly nullified. The decrease of the swelling capacity after illumination is not affected by a partial drying out of the agar during the period of illumination, but only by the ultra-violet rays. The hypothesis is advanced that the effect of ultra-violet rays upon plants is due to a lowering of the swelling capacity of the protoplasm in the cell-wall in the upper cellular layers of the plant.

M. H. SOULE

Hydration. ORTO BLÜH. *Protoplasma* 3, 81-115(1927).—A review, largely of the biol. significance of hydration. Sep. chapters are devoted to hydrophobic and hydrophilic colloids; the dielec. const.; H_2O as an amphoteric liquid; the hydration of ions and colloidal particles; the dielec. const. of true and colloidal solns., etc. An excellent bibliography, particularly of the German literature, is given. M. H. S.

Physiological ion antagonism. D. L. RUBINSTEIN. Med. Inst., Odessa. *Proto-plasma* 4, 259-314(1928).—A crit. review and discussion in German of the present knowledge of ion relations with examples of toxicity, permeability and irritability due to physiol. ion antagonism. Sep. chapters are devoted to this phenomenon as it appears in colloidal solns.; the influence of anions and cations, valence; electrolytic dissocn.; hydration; quant. relations; the effect of salts; the narcotics and glucosides. An excellent theoretical consideration and bibliography are given. M. H. SOULS

Wildier's bios. The isolation and identification of "Bios I." EDNA V. EASTCOTT. Univ. Toronto. *J. Phys. Chem.* 32, 1094-111(1928).—Lucas (C. A. 19, 2679) has shown that Wildier's bios can be sepd. into 2 constituents, "Bios I" and "Bios II." Eastcott's work started with the examn. of a large no. of vegetable and animal exts. according to the methods devised by Lucas. Eastcott's summary (cf. C. A. 20, 3481) may be used. *Summary.*—"The crops of yeast obtained under standard conditions from 48 vegetable and 15 animal preps. have been detd.; also the crops when either "Bios I" and "Bios II" or wort was added to the exts. From these results it is possible to predict, roughly, the crops obtainable from mixts. of 2 exts., on the assumption that in every case the bios in these exts. consists of Bios I and Bios II. The bios from 7 sources has been fractionated by Lucas' method into Bios I and Bios II. Bios has been isolated from tea dust; it proves to be identical with inactive inositol. Curves showing the rate of reproduction of yeast in solns. contg. salts, sugar, inositol and crude Bios II, agree in form with those obtained by N. A. Clark with solns. of salts, sugar and wort. The inositol taken up by yeast from the culture medium can be quantitatively recovered by hydrolyzing the yeast crop, each normal cell takes up and yields 1.2×10^{-13} g. of inositol, i. e., 1-2 parts per thousand of its own dry weight. Yeast grown in a soln. contg. only sugar and salts also yields inositol on hydrolysis, but less in amt." Full details of technic are given. F. W. TANNER

Interrelation of hydrogen ion activity and concentration of salt in the activation of pancreatic amylase. H. C. SHERMAN, M. L. CALDWELL AND M. ADAMS. Columbia Univ. *J. Am. Chem. Soc.* 50, 2529-35(1928).—The optimal H-ion activity for pancreatic amylase in the presence of different concns. of NaCl, KCl, NaBr, NaF, NaNO₃, NaClO₃, NaSCN or Na₂SO₄ has been quant. investigated. The optimal H-ion activity is dependent both upon the kind and concn. of salt present. In the presence of each of the salts investigated here, the optimal H-ion activity decreases with increasing concn. of the salt up to a certain salt concn., beyond which it ceases to be appreciably influenced; this concn. depends upon the salt. Na₂SO₄ and Na phosphate had no influence on the activity of pancreatic amylase. C. J. WEST

Influence of concentration of neutral salt on the activation of pancreatic amylase. H. C. SHERMAN, M. L. CALDWELL AND M. ADAMS. Columbia Univ. *J. Am. Chem. Soc.* 50, 2535-7(1928); cf. preceding abstr.—The following figures give the concn. of salt most favorable (in each case) to the activation of pancreatic amylase. NaCl 0.02-0.05 M, KCl 0.03-0.05, NaBr 0.03-0.20, NaNO₃ 0.10-0.20, NaClO₃ 0.10-0.20, NaSCN 0.15-0.20, NaF 0.20-0.30. The activity of the amylase is favored by more acid solns. in the presence of those salts of which higher concns. are required for its complete activation. C. J. WEST

Quantitative comparison of the influence of neutral salts on the activity of pancreatic amylase. H. C. SHERMAN, M. L. CALDWELL AND M. ADAMS. Columbia Univ. *J. Am. Chem. Soc.* 50, 2538-43(1928). cf. two preceding abstrs.—The influence of neutral salts on the activity of pancreatic amylase was found to be the same for the purified prepn. of the enzyme and for com. pancreatin and seems, therefore, to be a property of the enzyme itself rather than of any impurities that may be present. Each salt being used at its optimal H-ion activity and concn., the following comparative values were obtained: NaCl 100, KCl 100, LiCl 80-90, NaBr 77, NaNO₃ 41, NaClO₃ 29, NaSCN 29, NaF 24, Na₂SO₄ and Na phosphate 0. The salts which are less favorable to the activity of the amylase are required in higher concns. and in turn exert their most favorable influence in solns. of higher H-ion activities than do those salts which are more efficient activators. The activity of the amylase in the presence of 2 anions which exert a sp. influence on its activity, such as NO₃ and Cl, is intermediate between the activity of the enzyme in the presence of each taken separately. The activity of the enzyme in the presence of such a mixt. of salts is dependent on the relative concns. of the ions. Anions which alone do not influence the activity of the enzyme seem to have comparatively small influence on the activity of the enzyme in the presence of anions which exert a decidedly sp. influence. Reducing the concn. of enzyme by 0.5 or using 4% instead of 2% starch does not appreciably influence the concn. of NaCl necessary for complete activation of the enzyme or the optimal H ion activity. The presence of

neutral salt is essential to the activity of pancreatic amylase; the anion is of far more influence than the cation, although the latter seems to have some slight influence on the activity of the enzyme. Of the ions studied, Cl is the most efficient. The different anions have sp. effects on the enzyme or substrate. C. J. WAST

B—METHODS AND APPARATUS

STANLEY R. BENEDICT

Microchemical detection of potassium and calcium in histological sections. W. JACOBI AND W. KEUSCHER. *Arch. Psych. Nerv.* 79, 323-6(1927).—The tests depend, resp., on the formation of K chloroplatinate and CaSO_4 . B. C. A.

Detection of lactic acid in stomach contents. B. BISBINI. *Rinasc. med.* 3, 514-6(1926).—The stomach liquor (20 cc.) is evapd. at 70° to 2 cc., thoroughly extd. with ether (40-50 cc.), the residue after removal of the ether is dissolved in lukewarm distd. water (30-40 cc.), made alk. with CaO, filtered and the filtrate evapd. to dryness. The residue is treated with a little water, the soln. filtered, evapd. on the water bath to 0.5 cc., and the soln. placed on an object slide in a desiccator. The formation of Ca lactate crystals is observed with a microscope; 0.05% of lactic acid can be detected. B. C. A.

Some experiments on the amplification and detection of bioelectric currents by the use of thermionic valves. F. BENEDETTI. Univ. Bologna. *Atti accad. Lincei* [6], 7, 423-7(1928).—The method should be of value in investigations in *electrobiologie*, where the Einthoven galvanometer and the capillary electrometer have been the only methods used. With the app., the construction and use of which are described in detail, the existence of various bioelec. currents can be detected, in connection with which various expts. are described. Both intensities and frequencies can be estd. C. C. D.

Indican in urine tests. GERHARD MAUE. *Pharm. Ztg.* 73, 791-2(1928).—Reference is made to recent discussions on the subject by Schlecht, Otto, Aufrecht and others, and that the presence of indican in urine is frequently due to medication of the patient with certain drugs like $\text{CCl}_3\text{CH}(\text{OH})_2$, PhOH, terpenes and their derivs. (as in oil of turpentine, sandalwood oil, balsam copaiba, camphor), naphthalene and pyrazolone derivs. On stopping such medication the indican disappears. W. O. E.

Lange ring test for acetone in urine. GABRIELSEN. *Pharm. Ztg.* 73, 792(1928).—In applying this test attention is directed to the necessity of an AcOH free from AcMe. W. O. E.

A colorimetric method for the determination of free tryptophan in blood. C. A. CARY. U. S. Bur. of Dairy Industry. *J. Biol. Chem.* 78, 377-98(1928).—A method is given for non-protein tryptophan in blood based upon the Hopkins-Cole glyoxylic acid reaction in the presence of excess HgSO_4 . Blood samples are coagulated with AcOH, treated with kaolin, filtered, concd. *in vacuo* (20-25 mm.) and treated again with kaolin. Protein-free aliquots are removed as in amino-N detn., except that CCl_3COOH is omitted. These aliquots are diluted to a known vol. of about 1.5-2 times the sample represented by them. For this enough 33.5% H_2SO_4 is used to give 7% (by vol.) of concd. acid in the final soln. Tryptophan is pptd. from the soln. by dissolving in it 10 g. HgSO_4 per 100 cc. and allowing it to stand in an ice box 4-48 hrs. The ppt. is filtered on an asbestos mat. The original vessel and mat are washed 3 times, 10 cc. of 5% (by vol.) H_2SO_4 being used each time. The washed mat and ppt. are placed in the original vessel. Twenty cc. of freshly prepd. glyoxylic- H_2SO_4 reagent (Hopkins-

Cole) are poured through a Gooch filter into this vessel and 4 drops of a 25% HgSO_4 soln. in 10% (by vol.) H_2SO_4 added. The vessel is stoppered, left for 48 hrs. at room temp. (out of direct sunlight), and filtered through dry asbestos mats. The colored soln. is compared colorimetrically with tryptophan standards. Examd. spectrophotometrically the color matching is not as perfect as with the colorimeter. From 75 to 85% of blood material estd. as tryptophan is actually such; the remainder is probably a deriv. of tryptophan originally present. Therefore this method gives a fairly close approximation of the actual tryptophan present.

RUSSELL C. EBB

The determination of guanidine bases in urine. C. J. WEBER. *J. Biol. Chem.* 78, 465-73 (1928).—A colorimetric method using an alk. nitroprusside-ferricyanide soln. for the estn. of guanidine in urine is described. Methylguanidine, glycoeyamine and arginine in which 1 H atom is substituted, as diphenylguanidine in which 2 H atoms are substituted, all give a color with the reagent. Creatinine gives $1/30$ the color of guanidine while triphenylguanidine, tyrosine, tyramine, phenol and acetone produce no color. Acid-washed Norit adsorbs the bases from alk. solns. of urine, then on addn. of an acidulated H_2O or alc., the bases are again set free and can be detd. in the filtrate. The % recoveries averaged 90 when guanidine was added to urine. Normal human urine gives a color value equiv. to an excretion of 10-20 mg. of guanidine per 24 hrs. The substances responsible for this color are being investigated. The method should prove useful in studying the fate of guanidine compds. when introduced into the body.

C. R. FELLERS

Electrical resistance thermometer for continuous rectal measurements. WILHELM BAUCH. *Klin. Wochschr.* 7, 699 (1928).—A metal tube that contains a resistance wire with a high temp. coeff. is inserted into the rectum. This resistance wire is one branch of a wheatstone bridge couple that is spanned by a galvanometer. Current is supplied by a battery. Changes in temp. produce changes in the resistance of one branch of the circuit and lead, therefore, to deflection of the galvanometer. The galvanometer registers degrees and it can, of course, be placed anywhere in the patient's room.

MILTON HANKE

Radiometric determination of the quantity of body fluids. RUDOLF EHRENBERG AND WALTER KROPATSCHKE. *Klin. Wochschr.* 7, 847-9 (1928).—A quantity of Th B, measured radiometrically, is mixed with citrated blood and injected into the jugular vein. Blood is drawn after 7 to 10 min. and the radioactivity of 1 cc. is accurately detd. The blood vol. of rabbits was found to be 50-56 cc. per kg. body wt. The intravenous injection of a Th B soln. in water leads to a rapid disappearance of a portion of the radioactivity from the blood so that samples taken after 10 min. indicate a blood vol. of approx. 200 to 300 cc. per kg body wt. The Th B has obviously gone into the body tissues, possibly into the free water in the body tissues. This may be a method for estg. free water. The possible combination of Th B with body colloids is recognized and discussed.

MILTON HANKE

Reducing power of urine: clinically considered. CLIFFORD MITCHELL. *J. Am. Inst. Homeopathy* 21, 648-52 (1928).—*Collection of sample.*—No drugs are given for as long a time as possible. The daily ingestion of liquids is kept at 1 quart. The urine voided on rising is discarded; 3 samples are then collected: (1) from breakfast to bedtime, (2) from bedtime to breakfast, (3) after breakfast on the second day. The samples are kept cold, but no preservatives are used. *Determination of reducing power.*—Each sample is tested by adding 10 drops to 5 cc. of Benedict qual soln., placing in a bath of boiling water, and noting the elapsed time until a gelatinous green ppt. forms. In healthy persons this ppt. may not form within 10 min. "If the 24-hr. specimen of urine in question is of sp. gr. 1.015 or over and does not change in the water bath after 5 min. time and especially if it does not change when taken from the bath at the end of 5 min. and allowed to cool gradually, its reducing power is not likely to be worth considering. If, however, the change comes in less than 5 min. and especially if in 3 min. or less it may be safely assumed that the reducing power is greater than that of the person in av. good health." Urine of sp. gr. 1.010 or less may not effect the test in 30 min.; hence it should not be used. The longer the time required for the formation of the ppt., the more unlikely is the presence of glucose. JOSEPH S. HEPBURN

Microdetermination of creatine and creatinine in muscle. S. OCHOA AND J. G. VALDECASAS. *Rev. med. Barcelona* 8, 490-4 (1927); *Ber. ges. Physiol. expil. Pharmacol.* 44, 615.—Autoclave 5-100 mg. muscle (which may be removed from the living tissue) with 0.2 cc. 0.2 N HCl per mg. 24 min. at 120° in a tin-foil-covered flask, cool, add 0.2 cc. 1.2% picric acid, filter after 5 min., add 0.1 cc. 5% Na_2CO_3 to 0.2 cc. of the clear filtrate and compare after 5 min. with a standard soln. prepd. as follows: To 5 cc. of a soln. of 0.02 g. creatinine in 1 l. 0.2 N HCl add 5 cc. 1.2% picric acid and, as soon as

a turbidity appears, 5 cc. 5% Na_2CO_3 . The method is accurate and checks well with Hau and Schaefer's method.

MARY JACOBSEN

Legal procedure for poisoning with sodium tetraiodophenolphthalein. BEYREIS. *Deut. Z. Ges. ger. Med.* 10, 156-74 (1927).—Case report and discussion. F. K.

Recent methods for the determination of sodium and their biological application. M. LAUDAT. *Bull. soc. chim. biol.* 10, 757-68 (1928).—The $\text{K}_2\text{H}_2\text{Sb}_2\text{O}_7$ method as performed by Kramer and Tisdall (cf. *C. A.* 15, 2461, 3858, 3859), and the method of the triple acetate of Na, Mg and U as performed by Blanchetière (cf. *C. A.* 17, 3006), were experimentally reviewed and found to give the same results. The latter method is preferred for its greater simplicity.

L. W. RIGGS

Simple apparatus for sampling alveolar carbon dioxide. R. GOIFFON. *Compt. rend. soc. biol.* 99, 377 (1928).—The app. consists of a mouth tube, with valve, attached to one end of an elongated toy balloon, and a stopcock attached to the other end. With the tube open the subject makes a slow expiration at the end of which the stopcock is closed when by an addnl. short forced expiratory effort 50 to 100 cc. of alveolar air is received in the balloon.

L. W. RIGGS

Nuclear and differential tissue stain combined. GEORGE J. BRILMYER. *Science* 68, 114 (1928).—A new method for combining and manipulating Delafield's hematoxylin and Mallory's connective tissue stain is as follows: (1) Stain in Delafield's hematoxylin 5 min., (2) wash to remove excess of stain, (3) stain in 0.2% aq. soln. of acid fuchsin 1 min., (4) wash to remove excess of stain, (5) stain in the following soln. 2 to 3 hrs.: Aniline Blue (water sol.) 0.5 g., Orange G 2.0, and 1% phosphomolybdic acid 100 cc., (6) wash to remove excess of stain, (7) pass successively and rapidly through 35, 75 and 95% alc., (8) dehydrate in abs. alc. 30 to 60 sec. (anhyd. acetone may be used in place of abs. alc.), (9) clear in xylene, (10) mount with cover glass. With this procedure nuclei appear a rich red, epithelial cells pink, connective tissue blue and muscle red. Red blood corpuscles stain yellowish in veins, reddish in arteries. Colloid and mucus stain blue. Sections stained by this method have not faded in 5 years. L. W. R.

Blood samples for glucose determination sent by mail. HERMAN ROTHLIN. *Svensk Farm. Tids.* 32, 273-6 (1928).—Absorbent paper washed free from reducing substances, impregnated with NaF soln., dried, weighed and placed in rubber-stoppered vials are made up in numbers ready for use. The paper held by tweezers is brought into contact with the blood from a finger prick, returned to a vial and mailed to the lab. The net wt. of the blood is detd., the blood is extd. from the paper with water, and deproteinized with 45% ZnSO_4 and 0.2 N NaOH. The sugar is detd. by a micromethod.

A. R. ROSE

Determination of chlorides in blood serum. D. RAQUET. *J. pharm. chim.* 7, 487-9 (1928); cf. *C. A.* 22, 1194; and following abstr.—The $\text{Zn}_2\text{Fe}(\text{CN})_6$ method used in the detn. of Cl in milk is applied to the serum of the blood. To 10 cc. of serum add 100 cc. H_2O , 2 cc. of 15% $\text{K}_4\text{Fe}(\text{CN})_6$, shake, add 2 cc. of 30% $\text{Zn}(\text{AcO})_2$, H_2O to make 150 cc., shake and filter; to 100 cc. of filtrate add HNO_3 5 cc., 0.1 N AgNO_3 10 cc., shake, filter, and to 100 cc. of the filtrate add 1 cc. of 10% ferric alum and 0.1 N NH_4CNS until the red color appears. If A cc. is consumed, then NaCl (g. per l.) = $0.8775 (10-1.15 A)$. The results agree well with those by Laudat's method (*C. A.* 12, 1305).

S. WALDBOTT

Determination of total and of feebly combined chlorine contained in the gastric juice. D. RAQUET AND M. PAGET. *J. pharm. chim.* 7, 489-92 (1928).—The method of Hayem and Winter involves detn. in gastric juice (A) of (1) metal chlorides (B) (evap. A , calcine and det. Cl); (2) B + feebly combined Cl (remove free HCl by evapn. on the water bath and heat to 100° for 1 hr., then add Na_2CO_3 and KNO_3 , incinerate and det. Cl); (3) total Cl (to A add Na_2CO_3 , KNO_3 , evapn., ash and det. Cl). The method of R. and P. (see preceding abstr.; use 10 cc. of A , etc.) detn. total Cl (No. 3); the results agree well with those obtained by the methods of Laudat and of Hayem and Winter. To det. total Cl less free HCl (i. e., No. 2), expel free HCl from 10 cc. A as stated, then take up with 5 cc. of 20% HNO_3 , treat with $\text{K}_4\text{Fe}(\text{CN})_6$, $\text{Zn}(\text{AcO})_2$ and H_2O to make 150 cc., and proceed as before. The method is very rapid, since ashing the org. matter is not required. The feebly combined Cl is very unstable, dissociating in contact with the defecating solns.

S. WALDBOTT

Sugar in blood. A study of the accuracy of the Kramer-Gittleman modification of the method of Folin and Wu. ELSA R. ORENT. *J. Lab. Clin. Med.* 12, 433-8 (1927).—Comparison of the findings in the detn. of substances that reduce alk. $\text{Cu}(\text{OH})_2$ soln. were made on solns. of a known amt. of glucose ranging from 50 to 350 mg. per 100 cc., on blood of diabetic and nondiabetic patients, and on blood of dogs in convulsive seizures following ligation of the hepatic artery. The microtechnic of Kramer and

Gittleman gives results that compare well with those obtained with the original method of Folin and Wu.

Studies of quantitative blood-sugar estimation. Various methods compared with the author's micro-Folin-Wu method. THOMAS L. BYRD. *J. Lab. Clin. Med.* 12, 609-13(1927).—Comparisons were made which give further evidence that the micro-Folin-Wu method, using 0.1 cc. of blood, is just as reliable as any method now in use, irrespective of the quantity of blood necessary for respective techniques and regardless of the sugar content of the specimens analyzed. It can be applied to any case indicating the need of a quant. blood-sugar estn., including infants, small children and obese individuals. This is a method of preserving hemolyzed specimens of blood, giving 4 possibilities of a Folin-Wu analysis; making it feasible to collect and dil. specimens of blood with the blood-diluting pipet and transport any distance. E. W. W.

Nephelometry. HANS KLEINMANN. *J. Lab. Clin. Med.* 12, 629-43(1927).—The theory of nephelometry is discussed, a macro- and micro- nephelometer are described, and a new standard of turbidity is defined. General directions for nephelometric investigations are given, together with results obtained with the new type of nephelometer. Generally speaking changes in the colloidal state may be detected and gaged by variations in the dispersive power and consequently in the intensity of the light emitted. ETHEL W. WICKWIRE

Description of a new hydrogen-ion colorimeter. R. B. II. GRADWOHL. *J. Lab. Clin. Med.* 12, 694-701(1927).—This colorimeter is a box with a series of hermetically sealed special glass ampules contg. sterile buffers of known p_H value. The p_H value of each ampule is found on a metal strip running along the top of the rows. The indicator for each row is designated by initials on the end of the rack. Next, there is a series of indicator bottles properly labelled. The illuminating box is furnished with an arrangement for sliding back and forth along any one of these rows of buffers which are taken from the box for comparative purposes, after a rough test has been made and the actual indicator selected. The method of adjusting the reaction of culture media is described. ETHEL W. WICKWIRE

The preparation of colloidal gold solution. ROBERT A. KILDUFFE AND W. W. HERSON. *J. Lab. Clin. Med.* 12, 810-3(1927).—A method is outlined whereby sols. can be prepd. requiring a min. adjustment of reaction and which will invariably give normal curves with normal fluids and paretic curves with paretic fluids—a *sine qua non* before any colloidal Au is put into use. ETHEL W. WICKWIRE

Note on urine preservatives. J. J. SHORT AND A. PIATETZKY. *J. Lab. Clin. Med.* 12, 1098-1100(1927).—Quinosol and hexamethylenamine were found to be satisfactory preservatives in tablet form. ETHEL W. WICKWIRE

Determination of H_2SO_4 [in urine] (YAMAZAKI) 7.

CHARLES B. MORREY

The growth of *Bacillus radicola* on artificial media containing various plant extracts. F. H. ALLISON. *J. Agr. Research* 35, 915-24(1927).—*Bacillus radicola* obtained from red clover, which strain ordinarily makes a poor growth on simple sugar-salt medium, produced luxuriant growth in the presence of the juices of certain plants. The exts. were prepd. from 26 different plant materials covering a wide range of vegetables, fruits and field crops. The exts. from practically all the plants increased bacterial growth to some extent. The effect varied widely, however, both for the different plants and for different parts of the same plant. Ext. of legume roots particularly favored the bacterial growth. The bacterial food value of any particular plant species varied widely, depending upon the stage of maturity. Many strains of organisms showed increasing response to plants exts. after several transfers in the same medium. M. S. ANDERSON

Oxidation by means of *Bacterium xylinum*. I. The formation of dihydroxy-acetone from glycerol. K. BERNHAUER AND K. SCHÖN. German Univ. Prague. *Z. physiol. Chem.* 177, 107-24(1928).—An organism closely related to *Bacterium xylinum* converted glycerol almost quant. into $CO(CH_2OH)_2$. The culture medium consisted of 5% yeast ext. (prepd. by boiling 1 kg. pressed yeast 15 min. with 10 l. H_2O and centrifuging), 5% glycerol, and an org. acid was added to prevent contamination with

Aspergillus niger. The yield of $\text{CO}(\text{CH}_2\text{OH})_2$ was detd. by the Cu reduction method of Bertrand. Under optimum conditions, where the temp. was $27-8^\circ$, the p_{H} between 4 and 4.8, the depth of culture medium 1-2 cm. and the glycerol concn. 8-8%, the max. yield was obtained in 12 days. For suppressing contamination by *Aspergillus niger*, which was being cultivated in the same lab., the addn. of AcOH to a concn. of $N/30$ to $N/50$ was found desirable. CH_2O_2 , EtCO_2H and PrCO_2H were also used for this purpose but were less satisfactory. The bacteria form a membrane on the surface of the medium. If a uniform inoculation is desired, this may be made from a culture on a Ca gluconate medium where the membrane is much more easily broken up.

A. W. DOX

The effect of carbon dioxide on bacteria. GEORGE VALLEY. *Quart. Rev. Biol.* 3, 208-24(1928).—Review. Older papers are mainly concerned with the harmful effect of CO_2 . It was found later that CO_2 favors the growth of certain bacteria by either reducing the partial O_2 tension or by delicately adjusting the p_{H} . It was finally proved by Valley and Rettger (*C. A.* 20, 2870; 21, 3925) that complete removal of CO_2 from an otherwise favorable medium results in inhibition of development of 109 organisms examd.

MARY JACOBSEN

The fermentation of glucose by *B. coli*. ROSNATOVSKII. *Bacteriol. Inst. Kraznodar. Centr. Bakt. Parasitenk. I Abt.* 102, 145-8(1927).—The ratio of H to CO_2 in gases resulting from the fermentation of glucose by *B. coli* has previously been given as 2:1. For various reasons this does not always hold. If the medium is acid, the NaOH used in absorbing CO_2 from the mixed gases will release more CO_2 . Also if the bouillon was acid, the presence of 1% glucose gave about twice as much gas as did 0.5%. With neutral bouillon the percent of glucose made little difference. When the gas was analyzed by absorption of CO_2 with NaOH and explosion of the residuum in a eudiometer, it was found to be pure CO_2 and H. In acid media the H: CO_2 ratio varied from 6:1 to 10:1. In neutral media it was 2:1. The change from glucose to H and CO_2 goes by steps. A study of the intermediate products as, lactic, butyric and formic acids, will be of interest in explaining the mechanism of fermentation and perhaps in throwing light on the significance of the flora of the human intestine. J. T. M.

The antiseptic action of essential oils. I. Inhibitory action of a few vegetable essential oils and their constituents towards homogeneous cultures of human tuberculous bacillus. P. COURMONT, A. MOREL AND I. BAY. *Parfumerie moderne* 21, 161(1928). II. Antiseptic action and inhibitory action of some oils of mint and of their principal constituents. A. MOREL, A. ROCHAIX AND L. SEVELINGE. *Ibid* 163. IV. Inhibitory action of a few vegetable essential oils towards human tuberculous bacillus in vitro. P. COURMONT, A. MOREL AND I. BAY. *Ibid* 165-6.—See *C. A.* 21, 3928; 22, 1806, 1992. III. Weakening of the inhibitory action of essential oils towards microbes due to the colloidal state. A. MOREL, A. ROCHAIX AND A. CHEVALIER. *Ibid* 165.—The inhibitory action of essential oils towards the development of microbes is considerably lower when dispersed as a colloidal soln. than when in mol. soln., which is presumably due to the reduced contact between microbes and oil in the colloidal state. A. P.-C.

Thermophilic and thermoduric microorganisms, with special reference to species isolated from milk. I. Review of literature. A. H. ROBERTSON. New York Agr. Expt. Sta., *Tech. Bull.* 130, 56 pp.(1927); cf. *C. A.* 22, 1173, 1195.—Spore-forming thermophilic organisms are widely distributed in nature. A list of habitats from which they have been isolated is given. Physiologically and morphologically they resemble the common aerobic spore-formers. Only one non-spore-forming thermophilic *Lactobacillus thermophilus* Ayers and Johnson (1924b) has been isolated. Milk is the only recognized source of this species at present. Over 400 references are given. III. Description of the non-spore forming, thermoduric organisms isolated. *Ibid* 131, 62 pp.—A series of pasteurized milk plates from various cities in this country were sent to the New York State Agr. Expt. Sta. for a study of the so-called "pin-point" flora of pasteurized milk. A few heat-resistant cultures were also sent to the lab. Heat-resistant cultures were isolated by enrichment methods. A further selection of cultures was made by detg. the % reduction in the plate count after pasteurization. Where there was more than 80% survival the cultures were retained for further study. These cultures were divided morphologically into 5 types, which proved to belong to 5 distinct species. The utilization of various carbohydrates, some of the higher alcs., org. acids and amino acids was detd. Detns. of volatile acids from milk, *D*-glucose, lactose and sucrose were made at the end of 2 weeks. The amt. of NH_3 and amino-acid N and the titratable acid were detd. at various times up to 30 days. Three species, *Microbacterium lacticum* Orla-Jensen (1919), *Streptococcus thermophilus* Orla-Jensen (1919) and *Sarcina lutea* Schröter (1872) were common in milk. The "majority" of thermal death points

of the above species was above the customary pasteurizing temps. for milk. The presence of the above species in market milk as indicated by the fermentative studies is not regarded as dangerous to health. Their growth rates, with the exception of *Streptococcus thermophilus*, are relatively slow at temps. ranging between 20° and 37°.

E. F. SNYDER

Action of ray K of aluminum on some microorganisms. A. LACASSAGNE. *Compt. rend.* 186, 1316-7(1928).—Petri dishes contg. ordinary agar dried slightly in an oven were inoculated with a bouillon culture. Soon after inoculation the inoculated areas were irradiated with ray K of aluminum for varying lengths of time. *B. pyocyaneus*, *B. prodigiosus*, *Staphylococcus* and *Enterococcus* were used. With all of these microorganisms the effect of a few seconds exposure was readily apparent. On a surface corresponding to the aperture through which the rays emanated the growth was less opaque. The phenomenon was more pronounced for longer exposures. At certain exposures the colonies were isolated. Three phenomena were recognized—visible modification in the development of the culture, appearance of isolated colonies, and finally, complete sterilization. With *B. pyocyaneus*, 40 seconds radiation caused the appearance of isolated colonies but complete sterilization was not obtained after 5 min. exposure. Analogous effects were produced with *Staphylococcus* in 5 sec. and 3 and 10 min. The difference between exposure required for modifying the vitality of the organisms and that required to attain complete sterilization was considerable. L. suggested that the units in a bacterial suspension showed extreme degrees of variation in resistance to radiation due to some physiological peculiarity at the time of expt. or that some of the cells in a suspension were not exposed to the energy.

F. W. TANNER

An attempt to interpret the action of ray K of aluminum on microorganisms. F. HOLWICK. *Compt. rend.* 186, 1318-9(1928).—A theoretical consideration of explanations of the action of ray K of aluminum on bacteria. It is believed that in bacterial suspensions individual units may absorb different amts. of energy. It is conceivable that the same quantity of energy may produce different results on different bacteria. The theoretical assumptions and deductions may be best secured from the original paper.

F. W. TANNER

D—BOTANY

THOMAS G. PHILLIPS

Microchemical detection of organically combined sulfur and magnesium in plants. G. KLEIN. *Oesterr. botan. Z.* 76, 15-24(1927); cf. *C. A.* 22, 2964.—Neuberg's H_2O_2 method does not completely oxidize org. S; the material is instead exposed for several hrs. to Br vapor, the excess of which is removed by volatilization or by means of NH_4 . The sulfate is pptd. with $CaCl_2$, the crystals of $CaSO_4$ being observed on the next day. Mg compds. are removed from plant sections by extended treatment with water.

B. C. A.

Detection and physiology of urea in the higher plants. K. TAUBÖCK. *Oesterr. botan. Z.* 76, 43-56(1927).—An acetic acid ext. of the tissue or section, prepd. on a microscope slide or in a micro-extn. app., is treated with solid xanthidrol, yielding doubly-refracting dixanthylcarbamide, insol. in acetic acid or MeOH, and sol. in hot alc.

B. C. A.

Phosphatides of *Daucus carota*. V. GRAFE AND H. MAGISTRIS. *Z. wiss. Biol. Abt. 3 Plania, Arch. wiss. Bot.* 2, 429-37(1926).—The differences between denatured and native phosphatides are discussed. A diaminomonomophosphatide from *Daucus carota* yields as fission products palmitic, oleic and glycerophosphoric acids, choline and carbohydrates.

B. C. A.

Studies on the transport of carbohydrates in the cotton plant. II. The factors determining the rate and the direction of movement of sugars. F. G. MASON AND E. J. MASKELL. Cotton Research Sta., Trinidad. *Ann. Botany* 42, 571-636(1928).—The first paper of the series reported the diurnal changes in carbohydrates in the leaf, bark and wood of the cotton plant drawing the conclusion that the bark is the chief path of transport, and that the movement is analogous except in rate to movement by purely phys. diffusion. The present work is a closer analysis of the phys. aspects of the problem. Analytical data obtained with plants in which alternate leaves had been covered with lightproof covers indicated but did not prove conclusively that carbohydrate was transported from the illuminated to the darkened leaves. The direction of transport of carbohydrate was reversed in plants from which all but the basal leaves had been removed, and the base-to-apex gradient of concn. established in such plants was exactly the reverse of the apex-to-base gradient found in plants from which

the basal leaves had been removed, leaving the apical leaves intact. Removal of portions of the bark of varying width from the main stems, thus producing "constrictions" in the path of transfer, resulted in acceleration of movement through the remaining bark so that transport did not diminish in a degree proportional to the reduction of transporting tissue. When strips of bark of const. width but of varying length were removed, the reduction in carbohydrate transported increased with increase in length of the constriction. Sep. analyses of inner, middle and outer zones of the bark indicate that the channels of transport for carbohydrates are mainly within the inner zone, the radial concn. gradient being enormously greater than the longitudinal. The inner zone consists mainly of sieve-tubes and sucrose is the strongly predominant carbohydrate therein; the outer zone is largely parenchyma and contains chiefly reducing sugars. This indicates that the sieve-tubes are the chief avenues of longitudinal transport of sugars, and that only slight lateral diffusion into other tissues occurs with little resulting effect upon the concn. gradient. Interchange between sieve-tubes and parenchyma, between leaf and bark, bark and boll and bark and wood follows a diffusion pattern. Constriction in the path of transfer, as by partial removal of bark, increases the concentration gradient and thus the rate of transfer. The observed diffusion constant of sugar in the sieve-tube is approx. 40,000 times as great as in a 2% soln. of sucrose in water and is almost identical with the diffusion const. for mols. of the size of the sucrose mol. diffusing in air.

JOSEPH S. CALDWELL

A method of investigating and evaluating drought resistivity and the effect of drought conditions upon water economy. F. M. HAINES. East London College. *Ann. Botany* 42, 677-705(1928).—The coefficient of drought resistivity is a function involving both the satn. deficit within the plant and the transpiration rate. The method involves simultaneous detn. of the rate of evapn. by means of atmometers and of the rate of absorption of water by the plant through the stump of a detached side branch. The method is described in detail; results obtained in the study of some healthy plants are to be presented in a later paper.

JOSEPH S. CALDWELL

A physiological study of varietal differences in plants. I. A study of the comparative yields of barley varieties with different fertilizings. F. G. GREGORY AND FRANK CROWTHER. Imperial College of Science and Technology, London. *Ann. Botany* 42, 757-70(1928); cf. C. A. 22, 1428.—Five pure line varieties of two-rowed barley were used, the cultures being grown in pots in the open. Water percolating from the pots was collected and returned. The "complete" fertilizer contained N, K₂O and P₂O₅ in the ratio 3 2 1. The several "deficiency series" contained 2 of these constituents in unaltered amt. with 1/2, 1/3 and none of the third constituent. There were 7 replications of each series. The data, treated by Fisher's analysis of variance method, show a differential varietal response to fertilizing, significant values being obtained for roots, straw, total tops and total weight. The very large variations in dry weight and in no. of ears, particularly in the deficiency series, resulted in failure to obtain significant values for ears.

JOSEPH S. CALDWELL

The interaction of factors in the growth of Lemna. I. Methods and technic. ERIC ASHBY, B. D. BOLAS AND F. Y. HENDERSON. Imperial Coll. Sci. and Technology, London. *Ann. Botany* 42, 771-82.—A chamber for growing cultures in constantly circulating aerated soln., with controlled temp and illumination is described, as are methods for detg. area, dry weight and C content of individual fronds. J. S. C.

Relation of the distribution of certain Compositae to the hydrogen-ion concentration of the soil. J. ARTHUR TURNER. *Bull. Torrey Bot. Club* 55, 199-212(1928).—A study of the distribution of 75 species of Compositae over 6 representative soil areas of the Cayuga Lake Basin was accompanied by detn. of the reaction of the soils of each area. Dets. of p_H were made by colorimetric methods upon samples of soil brought into the lab. Of 620 samples, 294 were alk., 174 neutral and 147 acid. Of the 75 species, 15 were confined to soils of acid to neutral reaction, 42 to those of alk. to neutral reaction and 18 were widely tolerant of both acid and alk. soils. *Aster divaricatus*, *Ambrosia artemisiifolia* and *Gnaphalium uliginosum* were greatly reduced in size, vigor and no. of plants on soils which were strongly acid or strongly alk. in reaction.

JOSEPH S. CALDWELL

Studies on the growth of root hairs in solution. VII. Further investigations on collards in calcium hydroxide. CLIFFORD H. FARR. Washington Univ., St. Louis. *Bull. Torrey Bot. Club* 55, 223-46, 4 figs.(1928).—This post-humous paper reports the continuation of an extensive study (C. A. 22, 1793) of the rate of development of root hairs and of elongation of roots in Georgia collards (*Brassica oleracea*). In the present work solns. of Ca(OH)₂ of p_H 7.0 to 11.5 were employed. The growth of individual hairs was followed with the horizontal microscope, a culture chamber being employed

through which the soln. flowed at const. rate and nearly const. temp. The data confirm the earlier results in that the max. rate of elongation in root hairs occurs in Ca(OH)_2 at p_H 10. At p_H values between 10 and 8.5 the rate of elongation is greatly lessened, but rises to a secondary max. at p_H 8.0, declining again and becoming 0 at p_H 7.0. At concns. above p_H 10 it rapidly drops off to become 0 at p_H 12.0. Root elongation shows a max. at p_H 8.5 and falls off with increasing alk. Elongation of hairs on the 2 sides of the root is unequal; elongation occurs more rapidly on the side at which the current enters (affluent) in nearly neutral solns., and on the effluent side in more alk. solns. This difference is the result of the higher concn. of hydroxyl ion. The solns. flowing from the exit tube of the culture chamber had in all cases risen in H-ion concn. by 0.5 to 2.0 p_H in passing through the chamber. In the very dil. solns. of Ca(OH)_2 , here employed, the Ca ions are entirely consumed in root-hair formation while the OH ions penetrate the growing region of the root and affect its elongation. J. S. C.

Toxicity, additive effects and antagonism of salt solutions as indicated by growth of wheat roots. WALTER S. EISENMENGER *Bull. Torrey Bot. Club* 55, 261-304, 4 figs. (1928).—Employing the technic described by Trelease and Trelease and Barton and Trelease and using the same pure line of Marquis spring wheat, E. investigated the antagonistic and toxic effects of KH_2PO_4 , $\text{Ca(NO}_3)_2$ and MgSO_4 . Toxic effects were studied in solns. of the single salts ranging from 0.0004 M to 0.24 M . When used alone, each of the 3 salts retarded growth at all concns. within this range, except that MgSO_4 was slightly stimulatory at concns. below 0.0003 M . The comparative toxicity of the 3 salts varied with concn.; at low concns. the order of decreasing toxicity was KH_2PO_4 , $\text{Ca(NO}_3)_2$, MgSO_4 , at midrange, KH_2PO_4 , MgSO_4 , $\text{Ca(NO}_3)_2$ and at high concns., MgSO_4 , KH_2PO_4 , $\text{Ca(NO}_3)_2$. Antagonism was studied in two-salt mixts. at 5 total concns. from 0.002 M to 0.12 M and 11 different mol. proportions of the 2 salts were employed at each concn. Marked antagonism was observed in all the mixts. tested and was in most cases mutual as indicated by greater growth in mixt. than in a soln. of the less toxic salt. The wide range of salt proportions which allow nearly optimum growth is a striking feature at all concns.; growth is nearly equal over most of the range of mixts., falling off only when the concn. of 1 salt becomes quite low. Quant. indices of antagonism calcd. by Osterhout's additive effect method were inversely related to the total concn. of the soln. The bibliography contains 74 titles. J. S. C.

Long time experiments with plants in closed containers. RAYMOND H. WALLACE. Columbia Univ. *Bull. Torrey Bot. Club* 55, 305-14 (1928).—Culture chambers made from 500-watt elec. light bulbs are described, as are expts. with 12 species. Plants differ widely in their tolerance to conditions in closed containers and tolerant species are found in widely sepd. groups. The balanced gas relation in photosynthesis and respiration is not the only factor detg. survival. Ability to live in an approx. satd. atm. and to withstand the effects of possible deleterious metabolic end-products are suggested as playing roles in the result. In no case have plants in closed containers completed the life cycle by producing viable seeds or spores. JOSEPH S. CALDWELL

Radioscopy in vegetables. E. BARSALL. *Atti accad. Lincei* [6], 7, 681-4 (1928).—Radioscopy should become of great value in the study of the structure of plant tissues and pathol. or other abnormal changes in them. Illustrations are given to show the ease with which abnormalities are revealed. C. C. DAVIS

An improved method of growing turmeric in the Deccan. H. M. DESAI. Dept. Agr., Bombay. *Bull.* 135, 14 pp (1927).—In the growing of turmeric the nitrate-N content of the surface soil was increased from 0.26-0.27 to 0.42-0.50 parts per 100,000 by ridge cultivation with irrigation between the rows, as compared with the usual method of growing in beds and irrigating over the entire surface. A smaller increase was obtained in the nitrate content of the sub-soil. K. D. JACOB

The hydrogen-ion concentration of the sap of the normal cotton plant and that attacked by the stem weevil. T. LAKSHMANA RAO. Madras Agr. Dept. *Yearbook* 1926, 65-72 (1927).—H-ion detns. were made on aq. exts. of the roots and stems and on the undiluted leaf juice of healthy cotton plants and of plants injured by the cotton stem weevil. There was no consistent difference in the H-ion concn. of root exts. from healthy and diseased plants. In general, the stem exts. of diseased plants were slightly more alk. than those of healthy plants, the difference averaging about 0.09 p_H . The H-ion concn. of the stem exts. of 6 healthy plants of the same species varied from p_H 6.18 to p_H 6.25 and that of the leaf exts. from p_H 5.30 to p_H 5.37. In general, the leaf exts. of diseased plants were also slightly more alk. than those of healthy plants. Five-fold diln. of pure leaf juice increased the p_H value about 0.4, while the p_H values of root exts. were not considerably affected by changes in concn. The p_H of leaf juice increased 0.1 in 180 min. after extn. while that of stem exts. increased only 0.01 during the same

time. The results, in general, indicate that injury by the cotton stem weevil causes an increase in the alkyl. of the juices of the cotton plant. The investigations are being continued.

K. D. JACOB

Chemical studies on the ripening of rice seed and chemical properties of rice of the early ripening subvarieties. TETSUTARO TADOKORO. *J. Coll. Agr. Hokkaido Imp. Univ.* 20, Pt. 5, 333-54(1927); cf. *C. A.* 20, 2334; 21, 518, 1289.—In ripening the non-protein N of rice seed decreases and the diamino N, NaCl-sol. and EtOH-sol. proteins increase. The compn. of the chief protein, oryzenin, increases in sp. rotation, in free amino N and lysine but decreases in content of arginine and ash to a certain period when the isoelec. point increases in p_H and then these changes are reversed. In the middle part of the ripening period, the ash and P decrease, the acetyl value of starch increases and its sp. rotation decreases. Early ripening varieties are richer in fat, non-protein and H₂O-sol. protein N and lower in ash and protein N than later varieties. The oryzenin of the early varieties is lower in free amino N than that of the later varieties.

H. R. KRAYBILL

Physiological investigation of *Marchantia polymorpha* L. in pure culture. MARIE LILJENSTERN. Staatsinst. wiss. Pädagogik, Leningrad. *Ber. deut. botan. Ges.* 46, 370-82(1928).—*M. polymorpha* prefers a slightly acid medium. Ca(NO₃)₂ is a better source of N than (NH₄)₂SO₄. Urea N is unavailable while asparagine gives good initial growth but the plants die sooner than in cultures contg. Ca(NO₃)₂. The optimum Ca/Mg ratio varies with the p_H of the medium, and *M. polymorpha* will develop if only one of these elements is present.

LAWRENCE P. MILLER

Variations in the course of photosynthesis. N. A. MAXIMOV AND T. A. KRASNOSSELSKII-MAXIMOV. Inst. f. angew. Bot., Leningrad. *Ber. deut. botan. Ges.* 46, 383-91(1928).—By measuring the amt. of CO₂ absorbed during various 4-min. periods by leaves of barley, soy bean, buckwheat and millet plants, it is shown that, even under uniform conditions, photosynthesis does not take place at an even rate, but its intensity varies greatly, in some cases as much as 100% in the course of a few minutes.

LAWRENCE P. MILLER

Twenty-five years existence of the national institute for plant culture and plant protection in Munich. CHRISTMANN AND I. KL. WEIGERT. *Ernähr. Pflanze* 24, 4-13 (1928).—The history, organization and work of this institution are given. L. P. M.

Potassium and sodium salts compared in their action on guttation. W. MUNKELT. *Ernähr. Pflanze* 24, 66-7(1928).—Na salts are more active in repressing guttation than K salts.

LAWRENCE P. MILLER

Researches on the pigments of the plastids and on photosynthesis. II. The pigments of the plastids and their transformation in the living tissues of the plant. V. LYUBIMENKO. Botan. Garden, Leningrad. *Rev. gén. botan.* 39, 547-59, 619-37, 698-710, 758-66(1927); 40, 23-9, 88-94, 146-55, 226-43, 303-18, 372-81(1928).—A comprehensive review dealing largely with the investigations of L. and co-workers.

LAWRENCE P. MILLER

The toxic properties of West African ratsbane. M. RABINOVICH. *Bull. Imp. Inst.* 26, 143-7(1928).—The kernel of Magbevi nut (*Chailletia toxicaria*) from Sierra Leone was found to be toxic to white tame rats in doses varying from 9 to 12 mg. per 100 g. of body wt. The lethal dose varied within very wide limits, the min. observed being 5 mg. and the av. 36 mg., while the max. dose that failed to kill was 62 mg. per 100 g. The effect of the poison is cumulative and the min. lethal dose found by daily admin. is practically the same as if given in a single dose. The toxic principles appear to be thermostable, as the toxicity does not appear to be reduced by autoclaving. The shell of the nut has a very low degree of toxicity.

A. PAPINEAU-COUTURE

Methods of evaluation of the actual reaction of bog waters. I. A. SMORODINTSEV AND A. N. ADOVA. *Bull. soc. chim. biol.* 10, 806-11(1928).—The quinhydrone electrode method and the method without buffer solns. are utilizable for the detn. of p_H in acid bog waters. The nitrophenol series of indicators in detns. made in free air give results tending toward alkyl. The reaction of bog water detd. its flora, thus with a p_H 3.82 to 5.6 the vegetation was largely *Sphagnum*, and with p_H 7.4 to 8.47 the vegetation was largely *Carex*. Bog waters with acid reaction were poor in flora and fauna and the larvae of *Anopheles* were absent.

L. W. RIGGS

Soluble enzymes which are catalyzers of oxygen, secreted by hymenomycetes. L. LUTZ. *Bull. soc. chim. biol.* 10, 826-48(1928); cf. *C. A.* 19, 1585; 21, 3070.—An address. The main topics discussed with reference to enzymes secreted by 10 species of fungi are (1) oxidizing actions, (2) reducing actions, (3) simple antioxidant actions, (4) antioxidant actions superposed on reducing actions, (5) tannin as antioxidant.

L. W. RIGGS

Chemical constitution of chondriosomes and of plastids in plants. P. MILOVIDOV. *Compt. rend.* 187, 140-2(1928).—The chondriosomes of the mycelium of *Saprolegnia* and of the shoots of *Elodea*, also the plastids of *Tradescantia*, gave the usual color reactions for proteins.

Respiratory exchanges of plants attacked by Uredineae. MARESQUELLE. *Compt. rend.* 187, 247-9(1928).—An increase in the respiratory exchanges was observed in the invaded tissue but not in healthy adjacent tissue. The increase of exchanges caused by the parasite is dependent on the presence and abundance of mycelium and is due to the respiration of the mycelium. The result may be considered as the sum of 2 metabolisms.

Interrelation between diatoms, their chemical environment and upwelling of water in the sea off the coast of Southern California. ERIC G. MOBERG. *Proc. Nat. Acad. Sci.* 14, 511-8(1928).—Studies at stations 5 and 10 miles off the coast of California were made with reference to the conditions of growth of the phytoplankton and especially the diatoms. The factors detd. for depths up to 150 m. were no of diatoms, light, temp., salinity, pH , CO_2 , SiO_2 , NO_3 and PO_4 . An extensive development of diatoms occurred only in a narrow zone at a depth of 30 to 35 m. At higher levels the water was deficient in NO_3 and at lower levels the light was inadequate. Factors affecting the movements of the water were studied.

The destruction of the hydrocarbons of raw rubber by fungi (DE VRIES) 30. Pyocyanin, the blue pigment of *B. pyocyaneus* (WREDE, STRACK) 10.

E—NUTRITION

PHILIP B. HAWK

The relative assimilation by dairy cows of clover and alfalfa hays and of rations of different calcium and phosphorus content. W. A. TURNER, T. S. HARDING AND A. M. HARTMAN. *J. Agr. Research* 35, 625-35(1927).—Metabolism expts. with 2 lactating cows show a better assimilation of Ca and P from alfalfa hay than from clover hay. Analyses of feeds are given as well as analyses of milk and excreta. Expts. involving the use of rations where the content of P was increased by the addn. of $Na_2H_2PO_4$ and Na_2HPO_4 suggest a better assimilation of Ca and P when the value of the Ca/P ratio of the feed is 1.25 than when it is 2.5. Positive Ca and P balances are observed in a cow on a ration of good alfalfa hay and a good grain mixt., the milk yield being 19 kg. per day.

Metabolic changes in rickets. H. HENTSCHEL AND E. ZÖLLER. *Monatsschr. Kinderheilk.* 34, 248-53(1926).—In rachitic rats the total phosphoric acid was unchanged; the ability to synthesize a lactacidogenic substance from inorg. phosphoric acid and hexose was diminished.

Bird feathers and antirachitic vitamin. W. ROWAN. *Nature* 121, 323-4(1928).—It is suggested that feather oil may contain vitamin D.

Activation of ergosterol— 180° . T. A. WEBSTER AND R. B. BOURDILLON. *Nature* 121, 502(1928).—Vitamin D has been obtained by irradiation of ergosterol in alc. soln. at -180° to $+78^\circ$ (cf. *C. A.* 22, 2193).

Researches on the physiological action of alcohol. V. Effect of a sub-protein, sub-lipin and hypercarbohydrate diet on the nitrogen exchange of white rats. A. GALAMINI. *Univ. Roma. Atti accad. Lincei* [6], 7, 526-30(1928); cf. *C. A.* 22, 2407.—EtOH has a favorable influence on the resistance of white rats fed on corn starch with quantities of beer yeast diminishing from 0.20 to 0.03 g. This favorable influence does not depend upon a diminished consumption of proteins, for rats administered EtOH consumed more protein than those so fed.

Growth-promoting properties of vitamin D. A. L. BACHARACH. *Quart. J. Pharm.* 1, 49-60(1928).—It was found that refined soy-bean oil may be a good source of vitamin A, though devoid of vitamin D. The process of hardening has a destructive effect on the vitamin A, though the destruction is perhaps incomplete. The growth-promoting properties of vitamin D can be directly illustrated by the use of suitable basal diets.

The tripartite nature of vitamin B. ROBERT R. WILLIAMS AND ROBERT E. WATERMAN. *Columbia Univ. J. Biol. Chem.* 78, 311-32(1928).—A fuller's earth prepn. of the brewers' yeast, made with a special dialysis and adsorption app., is the source of the first or antineuritic factor of vitamin B. This is termed the *Y prepn.* Brewers' yeast autoclaved for 6 hrs. at 121° is the source of the second factor, the pellagra-prevention factor. Pigeons fed a synthetic basal diet, (No. 107, Sherman and Spohn) or polished rice, supplemented by special fullers' earth, drop to a sub-normal level in wt., appearance,

etc. Upon changing this diet to whole wheat, the birds regain their normal level. The same results are obtained when 1 g. of air-dried brewers' yeast is given every other day with the basal diet remaining the same. Since the same result is not obtained with autoclaved yeast or Y prepn. or both, as supplements, the pigeons' improvement in wt. and condition must be due to a thermolabile factor originally present in the yeast and which is different from the antineuritic factor in the Y prepn. This is concluded to be due to a *third factor* in vitamin B. The possibility of the presence of vitamins A, D and E as factors is eliminated experimentally.

RUSSELL C. ERN

The physiological significance of certain important constituents of vegetables with particular reference to lignin. MAX RUBNER. *Sitzb. Preuss. Akad. Wiss.* Nos. 11-12, 127-45(1928).—Data are presented showing the N, amino N, cellulose, pentosan and lignin content of all the common vegetables. The significance of lignin and cellulose in human nutrition is briefly discussed.

C. R. FELLERS

The importance of properly balanced rations in trials to determine digestibility as shown in experiments with dried apple pomace. C. W. HOLDAWAY, W. B. ELLETT, J. F. EHLEART AND M. P. MILLER. *Va. Agr. Expt. Sta., Tech. Bull.* 32, 1-18(1927).—Under balanced conditions the digestible coeffs. found for dried apple pomace, cows being used, were dry matter 67, crude protein 37, ether ext. 32, crude fiber 54 and N-free ext. 80%. Dried apple pomace, being a bulky feedstuff with a low protein and high energy content, widens the protein-energy ratio when added to a basal ration, thus causing a pronounced depression of digestibility of the protein of the whole ration. This general depression reduced the amt. of digestible protein in the whole ration to such an extent that the results show that apparently none of the apple pomace protein is digested, and furthermore that less of the protein in the basal ration is digested when this material is added to it.

C. R. FELLERS

The respiratory metabolism in infancy and in childhood. III. Glycogen storage in children. S. Z. LEVINE, J. R. WILSON AND H. RIVKIN. *Am. J. Diseases Children* 31, 496-503(1926); *Physiol. Abstracts* 11, 431; cf. following abstr.—An investigation was carried out on two normal girls, one obese girl, one girl subject to cyclic vomiting and one diabetic boy. A period of high carbohydrate, high caloric diet was followed by a fast of about 74 hrs., during which only small carbohydrate-free meals were given. The authors confirmed the fact that glycogenesis occurs during high carbohydrate feeding and glycogenolysis during starvation in all the cases studied except the diabetic boy. The relative quantities of carbohydrate mobilized and oxidized during short fasts was approx. the same in the normal children, nor was it diminished in the patient with cyclic vomiting between the attacks.

H. G.

The respiratory metabolism in infancy and in childhood. VI. The specific dynamic action of food in normal infants. S. Z. LEVINE, J. R. WILSON, F. BERLINER AND H. RIVKIN. *Am. J. Diseases Children* 33, 722-31(1927); *Expt. Sta. Record* 58, 593; cf. preceding abstr.—Using the app. and methods described in the first 2 papers of the series (*C. A.* 20, 1262), the authors have detd. the effect of various foods on the metabolism of two normal infants, aged 3 and 4 months. The basal metabolism of these subjects, as obtained during sound sleep and from 2 to 3 hrs. following small meals of cow's milk furnishing 62 and 34 cal., resp., equaled 42.5 and 41.4 cal. per sq. m. per hr. The test meals consisted of cream, glucose, casein and cow milk, resp., each furnishing approx. 125 cal. The fat, milk and protein meals raised the metabolism of one of the subjects 8, 4 and 15% above the basal level and of the other subject 1, 9 and 17% above the basal level in the 3 hrs. after ingestion. The metabolism of the second subject was also raised 8% above the basal level by the glucose meal.

H. G.

The action of chalybeate springs on the metabolism. M. KOCHMAN AND H. SEHL. *Vereinigten Friedrichs, Univ. Halle-Wittenburg. Deut. med. Wochschr.* 54, 1321-2 (1928).— $FeCl_3$, obtained from mineral springs, had an accelerating action on the growth of young rats.

ARTHUR GROLLMAN

The influence of the administration of aluminum upon the aluminum content of the tissues and upon the growth and reproduction of rats. VICTOR C. MYERS AND JAMES W. MULL. *State Univ. of Iowa. J. Biol. Chem.* 78, 605-13(1928).—The Al content of the tissues was detd. in 4 groups of rats: (1) on a control diet, (2) on a diet high in Al content, (3) on an Al-free diet and (4) following the intraperitoneal administration of Al. The minute traces of Al normally present in the tissues were only slightly increased by diet (2) and persisted even on diet (3). Following the intraperitoneal injection of Al, increasing amts. were found throughout the body, particularly in the liver. In 4 generations of rats receiving 2 mg. of Al, in the form of $KAl(SO_4)_2$, daily, no abnormalities were noted except a greater initial growth rate.

ARTHUR GROLLMAN

Factors affecting the accuracy of the quantitative determination of vitamin A. H. C. SHERMAN AND M. P. BURTIS. *Columbia Univ. J. Biol. Chem.* **78**, 671-80 (1928).—The factors affecting the results obtained in the detn. of vitamin A by the rat-growth method were studied. The diet fed to the mother and available to the young until sepd. from her, the size of the exptl. animal at the beginning of the test period and the length of the test period, all affect the final results. ARTHUR GROLLMAN

Polynuritis in pigeons and albino rats from deficiency of oryzanin (vitamin B). MOTOO IWATA. *Bull. Inst. Phys. Chem. Research (Tokyo)* **7**, 302-13 (1928); *English Ed.* **1**, 27-8.—Many of the symptoms of the so-called polynuritis in B-avitaminosis may be due to some trouble in the central nervous system. Puncture was practiced all over pigeon's brain, and the symptoms were observed only when the medulla oblongata was affected; all the symptoms peculiar to B-avitaminosis appeared; this affection bears some relation to the deficiency of oryzanin. The medulla oblongata was examd. pharmacologically with fufural. About 0.06 g. was effective to set up temporarily in a healthy pigeon such a spasmodic condition as seen in B-avitaminosis. By feeding a pigeon with an oryzanin-deficient diet, and injecting daily 0.02-4 g. of fufural, the susceptibility to fufural is increased. The convulsion caused thereby is only temporary, at first, but becomes gradually durable, and at last the convulsion continues for a few days by a single dose, ending in the death of the victim. At any stage, fufural loses its affecting power from the very next day of supplying oryzanin, thereby enabling the repetition of similar expts. several times. Again, by increasing the oryzanin-deficiency, a dose of 0.002-3 g. of fufural was effective; 0.5 cc. of con. oryzanin was enough to effect the recovery. Almost similar results were obtained with albino rats, except that the medulla oblongata did not show much change under the microscope; with pigeons, many perivascular and focal lesions were observed in this part and its neighborhood. Substances having a fufural-like role were obtained by decomp. carbohydrates such as glucose and gum-arabic by 5-10% HCl; these might be fufural and hydroxymethylfufural. The oryzanin deficiency affects first the whole medulla oblongata and other parts of the nervous system, causing functional disturbances and increasing the sensibility, then manifesting general symptoms through the whole body such as convulsion or paralysis, according to the nerve center which suffers the most. The disturbance of medulla centers essential to life seems to be the cause of mortality in B-avitaminosis. A. L. HENNE

Dental caries and pulp sequelae resulting from experimental diets. JOHN A. MARSHALL. *Univ. of Calif. J. Am. Dental Assoc.* **14**, 3-37 (1927).—Dental caries has not been found in young albino rats, even those of the 3rd generation, from parents on a diet deficient in vitamin A. However, caries develops in both males and females after maturity has been reached, and resembles that in adult man, rather than in the child or adolescent. Pulp lesions (e. g., pulp calcification) may occur in both carious and non-carious teeth. The caries of avitaminosis is not altered or arrested by addn. of vitamin A to the diet. The dental defects produced in dogs by deficient diets are not comparable to those produced in rats, since the dog does not show hypoplasia in either the enamel or the dentin. JOSEPH S. HEPBURN

Studies on vitamin deficiency diseases. TADASHI MASAKI. *J. Am. Dental Assoc.* **14**, 1654-6 (1927).—A diet deficient in vitamin C was fed to 51 guinea pigs. Exptl. scurvy resulted. The chief changes produced in the teeth were imperfect development of the dentin, enamel and cementum, calcific striations in the dentin, and hemorrhagic inflammation and accompanying disturbances in the pulp and pericementum. The enamel was influenced within 1 week after the beginning of the scorbutic diet. A diet deficient in vitamin A was fed to 32 albino rats; eye disease developed in 20 to 49 days. In their teeth, the enamel showed morphological changes (localized spots or markings accompanied by irregular course and arrangement of the enamel prisms); the collagenous layer of the dentin increased in vol., and improper deposition and fusion of the calcolayer of the dentin occurred. The cementum underwent central absorption. Circuloglobulin spherules occurred. The cementum underwent central absorption. Degenerative disturbances occurred in the soft dental tissues. The changes in bone and teeth resembled those in osteomalacia. The oral epithelium underwent atypical proliferation, hyperkeratosis and heterotopia within 47 to 73 days. The glandular cells of the salivary gland showed atrophy and necrosis, and the epithelium of its duct became cornified. CARCINOMATOUS change was not observed. JOSEPH S. HEPBURN

Behavior of the blood sugar in diabetic patients after ingestion of different carbohydrate-carriers without and with insulin. HERBERT MAUERHOFER. *Univ. Zürich. Z. klin. Med.* **105**, 641-60 (1927).—No evidence was obtained of the presence in oats of a principle which is absorbed from the intestine and lowers the concn. of the blood sugar.

None of the various carbohydrate-carriers had a distinct advantage over the others in decreasing the level of the blood sugar. Barley flour, white bread and bananas yielded varying results in parallel expts. on the same patient and on different patients. Addn. of butter retarded the decrease, while addn. of protein (beef) elevated the blood sugar curve above that given by oatmeal alone. The blood sugar was but slightly influenced by beef alone. When a second ingestion of carbohydrate occurred at an interval of approx. 3.5 hrs., no conclusions could be drawn concerning the blood sugar curve with respect to either the height of its turning point or the nature of its decrease. Insulin had a typical effect in decreasing the blood sugar concn.; this effect was markedly lessened in the course of even 5 hrs. With respect to the glucosuria, oatmeal was well tolerated by diabetic patients, bananas and barley even better by some patients. The unfavorable action of white bread or of oatmeal plus animal protein was attributed to the protein. Butter had no action on glucosuria. Relatively small doses of insulin did not markedly influence the urinary sugar. Repeated ingestion of small quantities of carbohydrate was followed by better utilization in the diabetic organism than ingestion of the same total quantity as one portion.

JOSEPH S. HEPBURN

The action of irradiated ergosterol on rickets. A. HOTTINGER. *Naturwissenschaften* 16, 484-91(1928).—Three cases are described of positive curative action of irradiated ergosterol on rickets patients in advanced stages, dose 3 to 5 mg. daily. The clinical action is discussed.

B. J. C. VAN DER HOEVEN

Direct and indirect determination of the energy value of milk in relation to the nutritional requirements of the newborn. ORESTE GARZIA and ELIA SAVINI. *Pediatrica Rivista* 36, 339-46(1928).—The caloric value of a no. of dairy milks was detd. directly and calcd. from the lactose, fat and protein content and with the aid of formulas based on the fat content alone. The latter calcn. gives better results than the former. Results obtained with a modified Andersen's formula, $C = 280 + 113.5 \times G$, where C = kg. cal., G = % fat, show satisfactory agreement with those detd. directly. The av. caloric value is 20-30; for milk with a high fat content it is 4-4.5% and above 4.7% it is 60 and 100 cal., resp.

MARY JACOBSEN

Experimental rickets in rats and the relation to ergosterol. ADOLF WINDAUS and FRIDRICH HOLTZ. *Nach. Ges. Wiss. Göttingen math. physik. Klasse* 1927, 217-25.-- Since antirachitic substances can be transmitted to animals during the placental period and afterwards through the mother's milk, it is necessary to begin with animals which come from a mother kept deficient in vitamin D. The method of prep., feeding and breeding such parents is given in detail. The following daily doses of irradiated substances were found to be antirachitic: 1 γ ergosterol, 10 γ of ergosterol distillate, 5 γ digitaligenin, 5 γ acetyldigitaligenin; these substances were useless when not irradiated. The following substances were of no value under any conditions: isoergosterol, oxycholesterylenes, nerolidol and ψ -ionone.

N. A. LANGE

Chemical changes in the blood during fasting and subsequent refeeding. II. Inorganic components. SERGIUS MORGULIS with V. L. BOLLMAN. *Nebraska Coll. Med. Am. J. Physiol.* 84, 350-62(1928).—The electrolytic compn. of the blood was maintained with tenacity in fasting dogs and cats, striking changes appearing in the more advanced stages of starvation. A fall of Cl was assocd. with a rise in plasma bicarbonate, the latter probably due to a toxicosis which developed at that stage of fasting. Ca undergoes diminution during fasting and is always found only in the fluid portion of the blood.

J. F. LYMAN

Effect of low protein and protein-free diets and starvation on the voluntary activity of the albino rat. FRED A. HITCHCOCK. *Ohio State Univ. Am. J. Physiol.* 84, 410-6(1928).—Low protein diet (12% protein) depressed voluntary activity in white rats. Protein starvation and complete starvation for short periods greatly increased activity. During a fast the material lost from a rat's body has an av. calorific value of about 5 cal. per g.

J. F. LYMAN

The effect of yeast upon metabolism. EUGENE V. STILL and ELIZABETH M. KOCH. *Univ. of Chicago. Am. J. Physiol.* 85, 33-44(1928).—With human subjects the addn. of yeast to a low protein, low purine diet, after a low uric acid elimination had been attained, caused no increase in uric acid excretion. If the yeast was added while the uric acid excretion was still high or while the subjects were on a high protein (meat) diet, an increased elimination of uric acid occurred. There was no increase in blood uric acid after several weeks of yeast ingestion. Total urinary phenols decreased with yeast feeding, indicating a decreased intestinal putrefaction. Total urinary N and P increased after yeast ingestion; but the larger part of the N and P of the yeast was found in the feces. The yeast feces were more bulky and softer than the controls and were generally more regularly and easily expelled.

J. F. LYMAN

The energy factor in relation to food intake. Experiments on the dog. GEORGE R. COWGILL. Yale Univ. *Am. J. Physiol.* 85, 45-64(1928).—When dogs under lab conditions were fed rations consisting of purified foodstuffs, but contg. all dietary essentials, the amt. eaten being limited by the animals appetite only, food consumption, regardless of the bulkiness of the diet, adjusted itself at approx. 64 cal. per hr. per sq. m., with a standard deviation of 8.4%. The appetite adjustment level for cal. for dogs can be calcd. as follows: $\log \text{ cal. per hr.} = 0.0162 L + 0.338$ (L = length of dog in cm. from tip of nose to anus). The maintenance level for the cal. requirement is estd. at 15% below the adjustment level. A table showing the requirements for dogs of different lengths is given.

J. F. LYMAN

Spontaneous deciduomata in pseudopregnancy with low vitamin E. HERBERT M. EVANS. Univ. Calif. *Am. J. Physiol.* 85, 149-53(1928).—The tendency for spontaneous uterine tumors to occur in the pseudopregnant rat was very greatly increased when the rations used lacked fat-sol. vitamin E, 60% of all animals on low vitamin E diets showing uterine tumors under the exptl conditions, while only 4% of those on complete diets showed such signs.

J. F. LYMAN

The influence of protein intake on basal metabolism. GEORGE MACFARLANE WISHART. Univ. of Glasgow. *J. Physiol.* 65, 243-54(1928).—There was a marked parallelism between the daily variations in basal metabolism and variations in the output of N in the urine. In one subject the lowest value for basal metabolism on a diet contg. 30 g. protein per day was 26.83 cal. per sq. m. per hr.; the max. value, when the diet contained 150 g. protein, was 40.39 cal. per sq. m. per hr. Differences in N metabolism did not fully account for the difference in basal metabolic rates of different individuals; hence other factors, possibly habitual differences in the caloric intake, may be involved.

J. F. LYMAN

Scorbutic avitaminosis and irradiation with ultra-violet rays. IZIO MILANESI. *Boll. soc. ital. biol. sper.* 3, 240-1(1928).—The effect of irradiation on vitamin C in dried oats was studied. Four groups of guinea pigs were used—1 received the non-irradiated oats, the other 3 received oats irradiated for 35, 45 and 60 min., resp. Irradiation failed to activate vitamin C. The animals fed with oats irradiated for 30 and 45 min. showed macro- and microscopic lesions of typical scurvy; those receiving oats irradiated for 60 min. died before the controls, although they showed no typical lesions of scurvy. The irradiation probably destroyed or altered other nutritive factors.

P. M.

Nitrogen metabolism I. Can ammonium salts be substituted for the proteins in nitrogen metabolism? UGO LOMBROSO AND S. DI FRISCO. *Boll. soc. ital. biol. sper.* 3, 303-7(1928).— NH_4 citrate and fats were administered to a group of albino rats; another group received NH_4 citrate and carbohydrates; a control group received only fats or carbohydrate but no NH_4 salts. The urine and feces were collected from each group and the N was detd. The animals were later killed, ground to a pulp and N was detd. The results showed that NH_4 salts did not influence the N metabolism, and did not stop the progressive loss of protein N. In a large no. of the rats the difference between the assumed N in the animal before the expt. and the N found in the dead animal did not balance with that found in the urine and feces during the expt. A large amt. of N (34-59.9%) was eliminated by routes other than the renal or intestinal. II. The routes of elimination of nitrogen during the absolute fasting of albino rats. *Ibid* 307-9.—Five albino rats were fasted until death. The N in the animal (calcd.) before the expt. did not balance with the N in the dead animal plus the N in the urine and feces collected during the expt. There was an unaccounted deficit of 36-8 to 65.0%. It must have been eliminated by other routes besides the renal and intestinal. This is a factor which must be recognized in all future N equil. expts. PETER MASUCCI

Synthesis of vitamin B by microorganisms. GERTRUDE SUNDERLIN AND C. H. WERKMAN. Iowa Agr. Expt. Sta., Ames. *J. Bact.* 16, 17-33(1928).—The synthesis of vitamin B by such biologically sepd. genera as *Torula*, *Oospora*, *Actinomyces*, and 4 genera of the order Eubacteriales reveals that vitamin B, whatever its chem. structure may be, is a constituent prevalent in microorganisms. There was no marked difference in the ability of 3 strains of *B. coli* to synthesize vitamin B. Drying at 37° or at 100° for 48 hrs. does not materially diminish the potency of the bacterial mass. There is a long bibliography.

JOHN T. MYERS

The pre-beriberi condition. With special reference to its existence in Japan. EGBERTON C. GRAY. Cambridge Univ. *J. Hyg.* 27, 257-67(1928).—A pre-beriberi condition manifested by general body weakness, affection of the heart, and in most cases loss of appetite and anemia, is very prevalent in Japan. Many cases now classed as beriberi are probably the pre-beriberi condition. It arises from a prolonged diet deficient not only in accessory but also in essential factors, in particular one which is

low in protein and high in starch. Hence rice-eating peoples are liable to it whether the rice is polished or not. The prophylaxis is milk, eggs and meat. J. T. M.

Studies in the nutrition of birds. EGERTON C. GREY. Egyptian Univ., Cairo, and Cambridge Univ. *J. Hyg.* 27, 268-94(1928).—On a similar diet, wild pigeons put on wt. more slowly and lose it more slowly than do town-bred pigeons. They represent 2 general types in the animal kingdom, the active or neuromuscular, and the passive or digestive. In the former the skeletal system is better developed and the food more completely utilized in producing energy, and there is less storage. There are 2 corresponding types in the Japanese human population, one characterized by the development of beriberi and the other by symptoms of exhaustion and general muscular weakness. A diet consisting exclusively of cereals, especially if overmilled, leads to a general metabolic disturbance, which affects in varying degree all the tissues of the body, of which the polyneuritic symptoms are but one manifestation, and by no means the most common even in birds. A study of the non-neuritic disease in birds may throw light on the similar syndrome in man. Various chem. factors, some in the tissues (fixed factors), some in the food or which may be formed in the body (mobile factors), as well as phys. and physiol. factors must be considered in explaining the disease induced in an animal by an entirely cereal diet, especially polished rice. There is much evidence of the accumulation of toxic material in the bodies of birds with rice disease, but it is not certain whether it comes from the tissue of the bird or from the rice. The trouble may be due to excessive metabolic work with an insufficient supply of nitrogenous repairing material. The action of the vitamin B complex may be attributed to 2 factors. One catalyzes enzyme action in the tissues, especially of the oxidative type; hence it is concerned in regulating energy production whether from carbohydrate, fat or protein. The other maintains tone of tissues. If absent the cells become autolyzed, permeable to fluids and finally disintegrate. JOHN T. MYERS

Relation between the nature of the carbohydrate in the diet and refection in rats. STANISLAW KAZIMIERE KON AND ELSIE WATCHORN. Cambridge Univ. *J. Hyg.* 27, 321-7(1928).—The phenomenon of refection was confirmed. The incidence of spontaneous growth of rats on a vitamin-B-free diet is very much greater when potato starch instead of rice starch is used. Raw arrowroot starch gives similar but not so good results. The protective action is largely destroyed by gentle cooking of the starch, and less so by alc. extrn. JOHN T. MYERS

The relative stability of vitamin A from plant sources. H. C. SHERMAN, E. J. QUINN, P. L. DAY AND E. H. MILLER. Columbia Univ. *J. Biol. Chem.* 78, 293-8(1928).—When tomato juice was heated at $98^{\circ} \pm 2^{\circ}$ for 4 hrs. destruction of vitamin A under either aerobic or anaerobic conditions was about 17%, as detd. by the effect of feeding heated and unheated juice to rats. No difference was observed between juice at p_H 4.2, and at p_H 9.2, heated to 100° . Olive oil ext. of spinach leaves lost 20% of its vitamin A content, while olive oil ext. of butter fat lost 33% of its vitamin A content. C. RIEGEL

Growth and maintenance of white mice fed synthetic diets. M. C. DAWBARN. *Australian J. Exptl. Biol. Med. Sci.* 5, 149-69(1928).—The diet recommended contained: casein 18 parts, dextrinized arrowroot starch 46, cane sugar 15, clarified butter fat 8, lard 7, salts 4, moist yeast contg. 75% water (corresponding to 3.7% dried wt. of yeast) 15. Upon this diet male white mice grew normally for 3 generations. This diet was less satisfactory for the growth and maintenance of female mice. A limiting factor in this diet appears to be the furnishing of vitamin B by yeast. L. W. RIGGS

Mode of action of vitamin B. H. BIERRY AND MAX KOLLMANN. *Compt. rend.* 186, 1062-4(1928).—The stimulating action of hydrosoluble vitamin B is exercised at the same time on the glands of external and internal secretion. L. W. RIGGS

Importance of manganese for animals. GABRIEL BERTRAND AND HIROSI NAKAMURA. *Compt. rend.* 186, 1480-3(1928).—Feeding tests were made with 6 series of young white mice by the same rigid technic observed in B.'s previous work with Zn, Ni and Co. Of the 34 animals used 28 completed the test. Thirteen fed without Mn survived on the av. 24.4 days, and 15 fed Mn survived on the av. 27.4 days. The animals fed Mn retained about 10 times as much Mn in their bodies as those not fed Mn. These results, with those of McHargue (cf. *C. A.* 20, 3488), indicate that Mn, which is always present in animals, takes some part in the nutritive exchanges. L. W. RIGGS

Water-soluble vitamins of Group B. Probable existence of a thermostable and alkalino-stable factor necessary to life. (MME.) L. RANDOIN AND R. LÉCOQ. *Compt. rend.* 187, 60-2(1928).—Neither fuller's earth activated by fixation of the antineuritic vitamin, nor ext. of yeast autoclaved in an alk. medium are capable of prolonging the life of pigeons fed a ration deprived of vitamin B. But the remarkable fact is that

fed a mixt. of these 2 products, the life is decidedly prolonged. It appears that the autoclaved ext. of yeast carries a water-sol. thermostable-alkalimostable factor which is indispensable to the pigeon and takes part in the cellular utilization of various nutritive principles, especially the sugars. The ext. of beer yeast deprived of the antineuritic factor contains both the nutritive thermolabile factor and the thermostable factor. It is probable that 2 g. doses of activated fuller's earth per day contain, in addn. to the antineuritic vitamin, a small quantity of the nutritive utilization vitamin. L. W. RIGGS

Comparative variations in the content of the liver and spleen in water, aliphatic acids and cholesterol in the normal guinea pig and in the guinea pig subjected to a diet deprived of antiscorbutic vitamin. (MME.) L. RANDOIN AND (MILE.) A. MICHAUX. *Compt. rend.* 187, 146-9(1928); cf. *C. A.* 20, 1437; 21, 1139.—The liver of the normal guinea pig contained an av. of 0.21% of cholesterol, 1.81 to 2.26 of aliphatic acids and 72.5 to 74.6 of water. During the last 6 days of a 32-day period of feeding a ration deprived of vitamin C, the cholesterol content of the liver generally increased, the aliphatic acid content increased and the lipocytic coeff. diminished. The spleen of the normal guinea pig contained an av. of 0.4% cholesterol, 1.4 of aliphatic acids and 78.3 of water. During acute scurvy the spleen increased in size and wt. As death approached the cholesterol and the aliphatic acids diminished and the water content increased.

L. W. RIGGS

Metabolism of sugars in inanition. G. MOURIQUAND AND A. LEULIER. *Compt. rend. soc. biol.* 99, 125-6(1928); cf. Bierry, *C. A.* 22, 1999.—A discussion of previous work.

L. W. RIGGS

Separation of antineuritic vitamins by means of fuller's earth. Nutritive utilization of beer yeast. (MME.) L. RANDOIN AND R. LECOQ. *Compt. rend. soc. biol.* 99, 148-50(1928).—Beer yeast extd. with 70% alc. and the alc. removed at reduced pressure yields a product, ext. B, which is usually employed as a source of nutritive and antineuritic vitamins B. To 100 g. of ext. B was added 1500 cc of water at a temp. of 30° and on filtering about 25% of the original 100 g. was removed. The filtrate was agitated with 45 g. and again with 30 g. of fuller's earth, when on filtering and drying about 75 g. of active earth TE was obtained. The filtrate evapd. in a vacuum at low temp. gave ext. E. Again 100 g. of ext. B was extd. with 1500 cc. of 70% alc., a cryst. ppt. was filtered out and the filtrate was agitated with 100 g. of fuller's earth in two 50 g. portions and filtered. The active fuller's earth thus obtained was designated by earth TA and the filtrate by ext. alc. A. The fuller's earth in an aq. medium takes up nearly all of the antineuritic vitamin and a portion of the nutritive vitamin. Ext. E contains almost exclusively the nutritive vitamin; earth TA contains almost exclusively the antineuritic vitamin; while ext. alc. A contains only the nutritive vitamin. The cryst. ppt. above mentioned probably contains a strong proportion of the nutritive vitamin.

Ketogenic diet treatment of epilepsy in adults. CLIFFORD J. BARBORKA. *J. Am. Med. Assocn.* 91, 73-8(1928).—Thirty-two adult epileptics were given a ketogenic diet. In 7 cases the attacks were controlled and in 12 other cases the patients were definitely improved. The remaining 13 cases were not definitely benefited although many of them were not maintained in a state of ketosis.

Absorption spectrum of vitamin A. R. A. MORTON AND I. M. HEILBRON. *Nature* 122, 10(1928).—A detailed spectrographic examn. was made of samples of a large and varied assortment of fish-liver oils and vitamin A concentrates. The chief result was the recording of a prominent absorption band at 328.5 μ , the intensity of which runs closely parallel with the vitamin A potencies of the various oils as measured by the SbCl₃ color test. Irradiation results in the disappearance of the chromogenic substance. Biological expts. proved that aeration or oxidation also causes the destruction of the vitamin, and these spectrographic tests indicate the same result. It is probable that the first decompn. products of vitamin A include a substance with an absorption band in the region 275-285 μ . The adoption of the 328 μ band as a criterion of vitamin A will assist in the elucidation of the chem. nature of the substance. L. W. RIGGS

Does the amount of food consumed influence the growth of the animal? H. H. MITCHELL. *Science* 68, 82-4(1928); cf. *C. A.* 21, 1292, 1478, 3934; W. C. ROSE, *Science* 67, 488; M. L. MITCHELL, *C. A.* 18, 2736.—A discussion of the fundamental principles underlying feeding expts. is given.

L. W. RIGGS

Morphological changes of the pavement epithelium of albino rats due to feeding on special diets. II. Relationship between morphological changes in the fore-stomach of rats fed on special diets and the constituents of the diets. YOSHITOMO FUJIMAKI, TETSUJI KIMURA, YOSHIHARU WADA AND SADAOKI SHIMADA. *Sei-i-kwai Med. J.* 47, 1-20(1928); cf. *C. A.* 21, 1836.—The degree of the morphological change in the fore-

stomach of the nature of hyperkeratosis, atypical epithelial proliferation, etc., is comparatively slight with animals fed on a diet deficient in both fat and vitamin A. Feeding a diet deficient in vitamin A to which heated olive oil was added often produces marked or moderate changes in the fore-stomach of albino rats, such as hyperkeratosis and papillomatous or carcinomatous growth. In a no. of cases moderately marked changes are to be observed in the forestomach of animals fed on fatty substances such as butter, butter fat and butter plus-cod-liver oil. These changes bear an intimate relationship to the obstruction of fat metabolism. Further work is in progress in the attempt to establish the causal factors of these morphological changes. L. W. RIGGS

Growth and development with special reference to domestic animals. XI. Further investigations on surface area with special reference to its significance in energy metabolism. SAMUEL BRODY, JAMES E. COMFORT AND JOHN S. MATHEWS. Agr. Expt. Sta., Univ. Missouri. *Coll. Agr. Research Bull.* 115, 60 pp. (1928).—Data are presented on the relation of surface area to body size of 482 dairy cattle, 341 beef cattle, 11 horses and 16 swine. A mathematical (graphical) analysis is presented of these original data, as well as of the available published data on the relation of area to body size and on the relation of heat production to body size. It is shown that the numerical value of the power in the power function relating surface area to body wt. varies from about 0.4 to about 0.7, depending on the relative variations in the linear size of the animals as compared to variations in body wt. In this connection the formulas of Meeh, of DuBois and DuBois and of Cowgill and Drabkin are subjected to critical analysis; as is also the so-called surface area law of Rubner. It is concluded on mathematical and on biological grounds, that while it may be more convenient, and perhaps more enlightening, to relate heat production to surface area, it is simpler to relate heat production directly to body size raised to some power by a method explained in detail in the text. E. F. SNYDER

The relation of diet to bodily activity and to capacity to withstand unfavorable circumstances. A. G. HOGAN, J. E. HUNTER AND C. L. SHREWSBURY. Missouri Agr. Expt. Sta., *Bull.* 256, 50-1 (1927).—Investigations as to whether or not vitamin E affects the rate of growth in any way have been made. Various synthetic diets, some of which contained vitamin E and some that were free from it, have been used. Rations made up of natural foodstuffs have also been used. The rats under observation have received the same ration that was given their mothers during gestation and lactation, with a few exceptions. The table indicates that the growth rate of animals was not affected by the presence or absence of vitamin E in the diet. E. F. S.

The calcifying potency of cod-liver oil. J. O. ELY, HANNAH E. HONEYWELL AND R. ADAMS DUTCHER. Penn. Agr. Expt. Sta., *Bull.* 213, 4 (1927).—A study has been made of a no. of medicinal cod-liver oils and proprietary cod-liver oil preps. with the view of detg. the min. quantity of each that will produce a standard amt. of calcification in a given time. It is impossible to bring about normal calcification with the Steenbock yellow corn ration supplemented with cod-liver oil. Small addns. of cod-liver oil prevent the development of rickets, but this rate of calcification soon reaches a sub-normal max. above which it cannot be forced by increased addns. of cod-liver oil. While the line test is useful, it is thought that the detns. of bone ash are more capable of quant. interpretation. E. F. SNYDER

Bone calcification in rats as influenced by ultra-violet light from various sources. HANNAH E. HONEYWELL AND R. ADAMS DUTCHER. Penn. Agr. Expt. Sta., *Bull.* 213, 5 (1927).—Ca deposition in the skeleton of rats has been used as an index of the physiol. potency of ultra-violet light from the quartz Hg vapor lamp and the C arc lamp. Both sources of light prevented the development of rickets although the amt. of calcification with the former was slightly superior to that obtained with the latter. Data also have been obtained relative to the irradiation of rats and rations, which indicate that it is preferable to irradiate the ration rather than the rats. An irradiation period of 5 min. daily seems to be less harmful than a 15-min. period and the amt. of Ca deposited during the shorter period is not appreciably less. E. F. SNYDER

Synthesis of vitamin B by bacteria in the rumen of cattle. S. I. BECHDEL, H. E. HONEYWELL, R. A. DUTCHER AND M. H. KNUDSEN. Penn. Agr. Expt. Sta., *Bull.* 213, 17-8 (1927).—A permanent opening or fistula was made into the rumen of a heifer through her left side to facilitate the removal of samples of fermented feed. Portions of about 30 lb. were removed each time, incubated from 2 to 5 days, and extd. with alc. to remove any vitamin B that may have been synthesized by the bacterial fermentations. This ext. has been fed to young rats as a supplement to a vitamin-B-free synthetic ration. Results have given very positive evidence that the ext. carries vitamin B growth factor. A study of the bacterial flora revealed the presence of an organism

which was predominant to the extent of about 90%. Results show that the dried bacterial cells are highly potent in vitamin B growth factor. It would appear that cattle, unlike any other species of animal yet studied, have the ability to synthesize their own needed supply of vitamin B through bacterial synthesis in the rumen. E. F. S.

Experiments with skim milk powder in the rations of dairy calves. S. I. BUCHHEI, Penn. Agr. Expt. Sta., *Bull.* 213, 19-20(1927).—An investigation was started during the past yr. to det. the advisability of feeding milk powder in the dry rather than in the liquid form. Thirty-five grade Holstein calves were fed experimentally in 3 groups. They were weaned to a dry ration when 34 days old. The oldest group of 12 calves made an av. daily gain of 1.36 lb. up to 6 months and was 95.7% normal in size. The milk powder was discontinued when they were 115 days old. These calves consumed a total of 105 lb. of milk powder, on the av., in addn. to 120 lb. of whole milk. The feeding of milk powder in the dry rather than the liquid form affords many advantages in labor-saving. The results prompt the advice that the calves should be changed to the dry ration at 6 weeks of age after feeding the powder in the reconstituted form up to that time. The dry mixt. at first should contain not over 45% milk powder, and preferably not over 40%. The % of powder should be reduced then as the calves grow older and consume more concentrates. E. F. SNYDER

The antineuritic vitamin and other substances having a bios character contained in rice bran. Y. KINUGASA, Tokyo Imp Hyg. Lab., *J. Pharm. Soc. Japan* 48, No. 6, 539-63(1928).—Aq. or alc. ext. of rice polish was treated with neutral or basic Pb acetate in neutral or acidic soln. After filtering the ppt. an excess of $(\text{AcO})_2\text{Pb}$ and $\text{Ba}(\text{OH})_2$ was added to the filtrate to a slightly alk. reaction. The yellow ppt. (I) thus obtained was filtered. Contrary to expectation, the antineuritic factor of rice bran (II) was found almost completely in I and not in the filtrate. Also contrary to the findings of Funk, Voegtlin, Peters and others for the antineuritic substance of yeast (III), II was found to be precipitable with HgSO_4 . The phosphotungstate of II was found sol. in dry Me_2CO , while F. found that that of III was insol. in it. From these facts K. concludes that II and III are not identical. By using the $(\text{AcO})_2\text{Pb}$ and $\text{Ba}(\text{OH})_2$ method of purification and the soly. of the phosphotungstate of II in dry Me_2CO , K. obtained an intensely active prepn. Daily doses of 5 mg. were effective in curing polyneuritic pigeons. A *picrate* of the active substance had the compn. $\text{C}_{19}\text{H}_{22}\text{N}_6\text{O}_7 \cdot \text{C}_6\text{H}_5\text{N}_3\text{O}_7$ and m. 198° . It also effected a rapid cure in neuritic pigeons with 5 mg. doses. A *cryst.* and an *amorphous* picrolonate were prepd. The former decompd. 320° and had the compn. $\text{C}_{14}\text{H}_{19}\text{N}_6\text{O}_{10} \cdot \text{C}_{10}\text{H}_8\text{N}_4\text{O}_6$, while the latter m. 204° and had the compn. $\text{C}_{18}\text{H}_{20}\text{N}_6\text{O}_7 \cdot \text{C}_{10}\text{H}_8\text{N}_4\text{O}_6$. Both picrolonates were also found to be effective in curing neuritic pigeons with 5 mg. doses. A *cryst.* substance with the compn. of $\text{C}_{19}\text{H}_{22}\text{N}_6$ and having a strong bios character was isolated. Since the substance active in curing polyneuritis was found to be ineffective in stimulating yeast fermentation and the substance effective in stimulating yeast fermentation was found to be inactive in curing polyneuritis, it is concluded that these substances are of different identity. More than 20 reactions were tested on 90 fractions of rice bran, but no specific reaction for II was found. NAO UYEI

Quantitative study of the photochemical activation of sterols in the cure of rickets. II. STANISLAW-KAZIMIERZ KON, FARRINGTON DANIELS and HARRY STEENBOCK, Univ. of Wisconsin, *J. Am. Chem. Soc.* 50, 2573-81(1928); cf. C. A. 22, 1614.—Repeated boiling with KMnO_4 in Me_2CO removes completely the provitamin from cholesterol. Cholesterol, purified in this way and irradiated, is inactive antirachitically even in large doses. The photochem. formation of vitamin D from ergosterol under the action of monochromatic light has been studied quant. for different lines. The quantity of radiant energy necessary to form an amt. of vitamin D sufficient to cause a demonstrable deposition of Ca in the bones of a rachitic rat has been found to be const. over a wide range of radiations, 700-1000 ergs, being necessary for the 256, 265, 280 and 293 $m\mu$ lines. The quantum efficiency was independent of the state in which ergosterol was irradiated, the results being the same for irradiation of the solid or of solns. in EtOH of varying concns. The quantum efficiency was the same for ergosterol acetate as for ergosterol. The HO group plays no role in the process of activation. C. J. WEST

Investigation to determine a satisfactory standard for beriberi-preventing rices (Vedder, Feliciano) 12.

Physiology of the fetus. T. SUGANO. *Kinki Fuji Gak. Zassi* 9, 97-100(1926).—Pepsin appears in the fetus at the fifth and sixth months. B. C. A.

Relation between urea in blood and saliva. A. BERGMAN AND I. BARG. *Rev. Soc. Med. Interna.* 3, 605-11(1927).—Detn. of urea in the saliva and blood serum of healthy and diseased subjects showed that the concns. in each were closely parallel, and the same variation occurred in each after oral administration of urea. If the normal amt. in blood serum is taken as 20-40 mg. %, the corresponding amt. in saliva is 30-50 mg. %. B. C. A.

An investigation on the relation between urobilinogen and the color of bile. EIJI WAKABAYASHI AND KOKICHI NAKASHIMA. *Imp. Univ. Acta Schol. Med. Univ. Imper., Kioto* 9, 343-50(1927).—From an examn. of urine and bile in cases of gallstones, the theory of the intestinal origin of urobilinogen is supported. In cases of liver disorder in which the bile obtained from the intestine contained mostly biliverdin (as detd. by its green color) no urobilinogen was found in the urine. It is believed that bilirubin is a necessary precursor for the synthesis of urobilinogen. H. J. DEUEL, JR.

Changes in the oxygen capacity of blood pigment of rabbits following partial hepatectomy. BARBARA B. STIMSON AND M. CAROLINE HRUBITZ. *Columbia Univ. J. Biol. Chem.* 78, 413-5(1928).—After removal of 75% of the liver in rabbits under ether anesthesia there was a reduction in the O-carrying power of the hemoglobin which lasted for 6 hrs. This condition did not occur in control animals in which a laparotomy but not a hepatectomy was performed. The condition is similar but less transient than the change following splenectomy (cf. *C. A.* 22, 113). It is suggested that another non-oxygen-bearing pigment is formed resembling methemoglobin but which has a characteristic spectrophotometric ratio of its own. H. J. DEUEL, JR.

Secretion of fat in the urine after percutaneous resorption. HANS MOSER AND ALBERT WERNLI. *Pharm. Zentralhalle* 69, 401-5(1928).—The application of fat (lard and tallow) to the arms and breast caused an appreciable increase in the traces of fat normally detectable in the urine. In 1 expt (30 g. of lard applied to the arms and breast) the increase in fat content of the urine was 10-fold. The expts. described in this paper are for other reasons of interest, in that they show a complete difference in the action of parenteral addn. of protein and of fat. The introduction of protein in other than peroral ways is followed by a variety of phenomena which are not alone serologically but therapeutically of the greatest importance. While the percutaneous introduction of an unusual fat induces no allergic phenomena whatever, the amts. thus introduced are, however, so large that a portion appears again in the urine, thus indicating that the intermediary metabolism of fats is entirely different from that of the proteins. W. O. F.

Free tryptophan in cow blood and its utilization in milk secretion. C. A. CARY AND EDWARD B. MEIGS. *J. Biol. Chem.* 78, 399-407(1928).—Free tryptophan in cow blood may vary independently of the free amino N. The standard *p*-dimethylamino-benzaldehyde method for the detn. of tryptophan was discarded in favor of the Hopkins-Cole reaction with glyoxylic acid and the oxidation of the tryptophan-glyoxylic acid condensation product by means of HgSO_4 . Tryptophan in the blood varied from 1.0 to 1.5 mg per 100 cc. with an av. of 1.12 while in the plasma it varied from 0.71 to 1.31 with an av. of 1.12. There was 17% more tryptophan in blood from the mammary vein than in blood from the jugular vein. Since there is a very much greater circulation of blood through the mammary glands during lactation, it is assumed that the free tryptophan in the blood plasma is utilized in milk secretion. Amino N detns. in the mammary and jugular veins show results similar to tryptophan. The increased amts. of tryptophan in the mammary blood are sufficient to account for the amt. of this amino acid required in the synthesis of the milk proteins. C. R. FELLERS

Studies in muscular activity. V. Changes and adaptations in running. J. H. TALBOTT, A. FÖLLING, L. J. HENDERSON, D. B. DILL, H. T. EDWARDS AND R. E. L. BERGGREN. *J. Biol. Chem.* 78, 445-63(1928).—Quant. observations were made to det. the main variations of the metabolism, and during each bout of work the metabolism and the properties of the blood as well as their variations as functions of time and of metabolic rate, were studied in detail. A N equil. was established in the untrained subject before starting the expts. A series of 6 work trials are reported in detail. Detns. of the principal urine constituents were also carried out. An adjustment of the body to the changed conditions is approx. complete in 15 min. and is followed by a steady state. In the preliminary period of adjustment rapid increases occur in

the O capacity and lactic acid content of the blood and there is a simultaneous fall in the CO₂ pressure of arterial blood. During moderate work there is little further change in the blood compn. During the period of recovery the long-continued utilization of O in amts. significantly larger than those characteristic of the basal condition is regarded as the result of 2 processes, (a) the completion of the oxidation of substances already in process of utilization at the moment when work ceased and (b) gradual restoration of the original condition of the body, so far as is possible in the absence of food, by means of partial and incomplete oxidation of existing components. C. R. FELLERS

The solubility in the stomach and duodenum of aluminum compounds found in baking-powder residues. VICTOR C. MYERS AND J. A. KILLIAN. N. Y. Post-Graduate Med. School. *J. Biol. Chem.* **78**, 591-4 (1928).—Studies of 18 human subjects showed an av. of about 25% of the Al present in the gastric contents to be present in a sol. form. The soly. varied from 6 to 54% and had no direct relation to the gastric acidity. ARTHUR GROLLMAN

The relation of copper to the hemoglobin content of rat blood. Preliminary report. J. S. MCHARGUE, D. J. HEALY AND E. S. HILL. Kentucky Agr. Expt. Station, Lexington. *J. Biol. Chem.* **78**, 637-41 (1928).—Analyses of the inorg. cations present in cow's blood and in calf's liver are given. The addn. of Cu to the diet of rats led to notable increase in the Hb content of their blood. ARTHUR GROLLMAN

Studies in the metabolism of the bile. II. The sequence of changes in the blood and bile following the intravenous injection of bile or its constituents. CARL H. GREENE AND A. M. SNELL. Mayo Clinic. *J. Biol. Chem.* **78**, 691-713 (1928).—Intravenously injected whole bile, bilirubin and bile acids rapidly disappear from the blood stream. The curves of excretion of bile acids and bilirubin by the liver show that the former are excreted by an increase in the vol. of the bile while the latter causes an increase in its concn. ARTHUR GROLLMAN

Studies of gas and electrolyte equilibria in blood. X. The solubility of carbon dioxide at 38° in water, salt solution, serum and blood cells. D. D. VAN SLAYKE, JULIUS SENDROY, JR., A. B. HASTINGS AND JAMES M. NEILL. Rockefeller Institute. *J. Biol. Chem.* **78**, 765-99 (1928).—The deviations of the soly. of CO₂ in serum from its soly. in H₂O are attributed to the following factors: salts, depressing the soly. 3% by lowering the solvent power of the H₂O for CO₂ and by displacing a small quantity of H₂O; proteins, depressing the soly. several percent by displacing H₂O; lipoids, raising the soly. about 4%. The combined effect is to reduce the soly. in normal serum to 93 to 94% of its soly. in H₂O. In lipemic serum, the soly. may exceed that in H₂O. Between 1/2 and 1 atm., the soly. of CO₂ in serum or a soln. of red blood cells was independent of the pressure. There was no deviation from Henry's law as would be expected if any of the colloids of serum or cells adsorbed any CO₂. The Bunsen soly. coeffs. for CO₂ or H₂O, normal human serum, lipemic serum and ox-blood cells, at 38° were 0.545, 0.510, 0.552 and 0.44, resp. In aq. solns. of the Cl⁻, lactates, and HPO₄⁻ of K⁺ and Na⁺, the depressions of the soly. coeffs. per mol. of electrolyte were found to be additive functions of the depressions due to the individual ions. The soly. coeff. of CO₂ in serum as found in this investigation does not necessitate revision of the serum p_H values in the literature, calcd. by Hasselbach's equation. A. G.

Studies of gas and electrolyte equilibria in blood. XI. The solubility of hydrogen at 38° in blood serum and cells. D. D. VAN SLAYKE AND JULIUS SENDROY, JR. Rockefeller Institute. *J. Biol. Chem.* **78**, 801-5 (1928).—Ox serum dissolved, per unit vol. at 38°, 90.3% as much H₂, and ox cells 89.8% as much, as was dissolved by H₂O. Per g. of H₂O present, serum dissolved 6% more and cells 24% more than was dissolved per g. of H₂O in 0.15 M NaCl soln. The org. constituents, therefore, dissolve considerable amts. of H. ARTHUR GROLLMAN

The hormone of the anterior lobe of the hypophysis. Preparation, chemical properties and biological action. BERNARD ZONDEK AND S. ASCHHEIM. *Klin. Wochschr.* **7**, 831-5 (1928).—A clear presentation and addnl. evidence to prove the exptl. findings reported previously (cf. C. A. **21**, 1837; **22**, 1182). The hypophyseal hormone is injured by heating in aq. soln. to 60° and is destroyed at 100°. It is destroyed by strong acid or alkali, is sol. in H₂O and insol. in lipid solvents. Ovarian hormone can be heated to 200° with impunity, is not destroyed by strong acid or alkali, and is readily sol. in H₂O and in lipid solvents. MILTON HANKE

Does the intestinal wall participate in the excretion of hydrogen ions from the body? K. SCHERR. *Klin. Wochschr.* **7**, 835-6 (1928).—The administration of 7-10 cc. of normal HCl or of 2-3 g. NaHCO₃ to infants leads to a prompt elimination of acid or alkali, resp., by the kidney, but the reaction of the feces remains unchanged. Cf. C. A. **20**, 1438. MILTON HANKE

Excretion of the female sexual hormone. M. DOHRN AND W. FAURE. *Klin. Wochschr.* 7, 943(1928).—The female sexual hormone is excreted into the intestine during pregnancy. As much as 30,000 mouse units can be isolated from 1 kg. dried feces.

Simultaneous fractional investigation of the stomach and duodenal juices. A. M. MARKOFF. *Deut. Arch. klin. Med.* 155, 129-40(1927).—The entrance into the stomach of juice from the duodenum causes a decrease in acid chloride, but an increase in total chloride of the gastric juice. The total concn. of Cl ion in the gastric juice is not an index of the HCl secreted by the stomach; but the amt. of neutral chloride is a relative index of the extent to which duodenal juice has entered the stomach. Two types of subacidity of the gastric juice are observed: true, in which little Cl ion is present; and apparent, in which is found a considerable amt. of neutral chloride from the duodenum.

The specific dynamic action of protein and its relation to muscular exercise. KARL BAHN. *Deut. Arch. klin. Med.* 156, 67-71(1927).—In normal individuals no change in the specific dynamic effect was caused by moderate exercise after a meal of 200 g beef.

The influence of suggestion upon stomach and pancreas secretions during hypnosis. F. DELHOUGNE AND K. HANSES. *Deut. Arch. klin. Med.* 157, 20-35(1927).—During hypnosis, suggestion that the subject was consuming a meal rich in fat caused not only an increase in the vol. of digestive juices secreted in the stomach and duodenum, but an increase in lipases corresponding to the increase noted following the actual ingestion of fat. The other enzymes were not secreted in response to the hypnotic suggestion of fat. Suggestion of a meal of meat caused a rise in acid and pepsin to values actually produced by such a meal; but lipases were lacking. Suggestion of carbohydrate increased the amt. of diastase, but not of the other enzymes. Suggestion during the hypnosis of unpleasant events caused the complete cessation of secretion of the digestive juices.

Total chloride concentration and acidity of the gastric contents. A comparative study. F. D. GORHAM, C. MALONE STROUD AND MAITLAND HUFFMAN. Washington Univ. School of Medicine. *Arch. Internal Med.* 42, 106-16(1928); cf. Baird and Campbell, *Guy's Hospital Report* 74, 40(1924); *C. A.* 16, 3331; 18, 1136.—In normal fasting subjects the av. free HCl was 7.2, total acidity 16.5, total chlorides 92.95 cc. 0.1 N/100 cc. Forty-five min. after a test meal of 400 cc. distd. water contg. 6 mg. phenolsulfonephthalein the corresponding values corrected for the meal diln. (Gorham) were: 16.4, 30.1 and 89.91. In a gastroenterostomized subject with fluid hypermotility (disappearance of the dye from the gastric contents after 30 min.) there was a marked variation between free HCl and chlorides. In gastric achylia of pernicious anemia the av. chloride content was 57.9, in duodenal ulcer, disease of the biliary tract and benign pyloric obstruction it was above normal: 122, 114, 170, but not higher than found in a group of miscellaneous cases (hypo- and hyperacidity, constipation, chronic appendicitis, neurosis). There is no relation between total chlorides and free acid in health and disease. The chloride concn. (Volhard) especially in subjects with achylia is not necessarily an index of the HCl production by the gastric glands.

Gastric secretion. Its alteration by the use of atropine, adrenaline and pilocarpine. A. M. ALTSCHULER. *Arch. Internal Med.* 42, 117-34(1928); cf. Altschuler (*Ann Clin. Med.* 5, 464(1926)); Gurvitch (*Trudy 7go. sjezda Terapevtov* 7, 280(1925)).—The gastric contents are examd. at the end of a 14-hr. fast and 4 times after a test meal of 200 cc. plain broth at 15 min. intervals. Then the test meal procedure is immediately repeated. There are 5 types of gastric secretion: (1) Normal: total HCl after the 1st meal (A) is 15-25% higher than that after the 2nd meal (B). (2) Asthenic: A > B. (3) Inert: B is up to 50% higher than A. (4) Isosecretory: A = B. (5) Torpid: A and B = 0. (5) may be functional or org. The effect of a subcutaneous injection of 0.0013 g. atropine-H₂SO₄, 1 cc. 0.1% adrenaline-HCl, 0.01620 g. pilocarpine-HCl on each type was studied. (1) is converted into (2) by atropine and adrenaline, into (3) by pilocarpine. Similar conversions of one type into another were found in various pathologic conditions. Functional (5) may be converted into (3) by adrenaline, but in org. (5) (cancer of the stomach, pernicious anemia and other conditions of gland exhaustion) the 3 drugs not only do not stimulate, but often even inhibit, a still existing secretion. The contradictory results obtained by some authors regarding the action of the 3 drugs may be attributable to the fact that their observations were made in different phases of digestion and drug action.

Physicochemical studies of woman's milk. MABAMI NAKAYAMA. *Kyoto Ikadai*

MARY JACOBSEN

gaku Zasshi 1, 69-70, 1003-34(1927); *Ber. ges. Physiol. exptl. Pharmacol.* 44, 598.—There is no definite relation between sp. gr., surface tension and relative viscosity. The latter decreases with rising temp., and is increased by the addn. of ions in the order: $\text{Na} > \text{Ca} > \text{K}$ and $\text{F} > \text{Br} > \text{I} > \text{Cl}$. Woman's milk buffers $1/1280$ - $1/1500$ N HCl, and completely pptd. after 1 hr. at 40° . The isoelec. point of dissolved casein shows no relation to salts added: KCl, NaCl, CaCl_2 . Nephelometric especially diffusimetrically increased by diln. with water.

Relation between hemoglobin content and reducing power of blood. E. BAUER, K. LAVROVSKII AND E. SKUINI. *Moskovskij med. zhurnal* 7, 105-12(1927), *Ber. ges. Physiol. exptl. Pharmacol.* 44, 659.—The oxidizability increases inversely with the hemoglobin content. This is particularly pronounced in polycythemia and in anemias.

Liver and mineral metabolism. KURT BECKMANN. *Verh. deut. Ges. inn. Med.* 1927, 250-4, 281-93; *Ber. ges. Physiol. exptl. Pharmacol.* 44, 645.—NaCl, KCl, CaCl_2 , NaHCO_3 and Na_2HPO_4 were injected into the jugular and portal veins, resp. (rabbits) and the blood of the carotid (I) and hepatic (II) veins was examd. The effect on I was considerable and protracted, that on II slight and of short duration, showing the effectiveness of the liver in the maintenance of the ionic equil. The increase of Ca and P was about the same in both cases. Portal injection of K was followed by K mobilization.

Simple methods of orientation on the blood proteins. ISTVAN HETÉNYI. *Verh. deut. Ges. inn. Med.* 1927, 342-4; *Ber. ges. Physiol. exptl. Pharmacol.* 44, 665.—The practitioner is advised to det. the sedimentation velocity (s. v.), the fibrinogen (I) and the globulin (II). There is an almost mathematical relation between s. v. and II/I. The formol reaction is suitable for the detn. of II. The gelation times are 24, 4 and 2 hrs., resp., for II contents of 35% (normal), 40 and 50%. No gelation takes place below 35%. The reactions may serve for differential diagnosis in subfebrile conditions. In chronic obstructive jaundice the relation between s. v. and II/I does not obtain, but the formol gelation is not affected by bile salts.

The organic substance of human dental enamel. FRITZ FABER. *Z. Anat. Entwicklungs-gesch.* 86, 1-70(1928).—A critical review. Some of F's results are given.

Studies of the thyroid apparatus. XXXII. The role of the thyroid apparatus in the solids-water differentiation of the central nervous system during growth. FREDERICK S. HAMMETT. *J. Comp. Neurol.* 41, 205-22(1926); cf. *C. A.* 22, 266.—A distortion of the water-solids differentiation of the brain and spinal cord is caused by thyroid and parathyroid deficiency. This distortion consists of a greater retardation of increment in water than of increment in solids. The result is a brain and spinal cord of lower water content than that to be expected for the size according to age. No differences because of sex were noticed. Puberty increases the extent of distortion. The distortion produced by parathyroid deficiency is generally less than that produced by thyroid deficiency.

The chemical physiology of the placenta with special reference to the action of choline. H. SIEVERS. *Z. Biol.* 87, 319-26(1928).—Choline assocd. with small quantities of neosine and spermine were isolated from the placenta. The procedure involved freeing from albumin by concn. and treatment with hot alc. To the alc. supernatant fluid was added Hg sublimate, and the Hg salt heated with H_2SO_4 . Treatment of the filtrate with AuCl_3 yielded cholin aurate, $\text{C}_8\text{H}_{14}\text{NO AuCl}_4$, m. 243° . From the mother liquor was obtained neosine aurate, $\text{C}_8\text{H}_{14}\text{NO AuCl}_4$, m. 205° , and spermine aurate, $\text{C}_{10}\text{H}_{24}\text{N}_4 \cdot 4\text{HCl} \cdot 4\text{AuCl}_4$, m. 218° . Discussion regarding the function of choline in the uterus is given.

Experiments on the chemical constitution of the genital glands. II. The amino acids of the ovary of Strongylocentrotus lividus in the various periods of the functional cycle of the organ. G. RUSSO. *Arch. sci. biol. (Italy)* 8, 293-309(1926).—The variations in the protein and non-protein fractions of the free and combined amino acids of the ovary of *S. lividus* were studied under different states of functional activity. The protein N increased; the non-protein N remained the same. The compn. of the protein was modified by an increase in lysine and a decrease in histidine and cystine. In the amino acid fraction, the ratio between monoamino acids and hexone bases increased. Free amino acids increased up to the end of the functional cycle of activity, but decreased rapidly at the beginning of the next cycle. The ovary and testicle, although similar in structure at the immature functional state, differ in the compn.

of the major N fractions. This difference becomes more marked as maturity progresses.

PETER MASUCCI

The action of pancreatic secretion on the absorption of fatty acids in depancreatized dogs. U. LOMBROSO. *Boll. soc. ital. biol. sper.* 3, 295-98(1928).—The substitution of equiv. amts. of oleic acid for olive oil in the diet of totally depancreatized dogs did not increase the fat absorbed; when olive oil was fed, 93.5% of fat was eliminated in the feces; with oleic acid 93.7% was eliminated. With partially depancreatized dogs,* the substitution of oleic acid did increase the fat absorbed; e. g., with olive oil 46.6% was absorbed, with oleic acid 78.8% was absorbed. The administration of oleic acid, glycerol and pancreatic secretion or pancreatic exts. to totally depancreatized dogs also favored the absorption of fats, e. g., without pancreatic ext. or secretion, 30.0% was absorbed; with pancreatic secretion 65.6% was absorbed. L. advances the theory that the external secretion of the pancreas has a synthesizing action on oleic acid, transforming it to neutral fats which are absorbed.

PETER MASUCCI

The chemical composition of follicular liquid. II. G. B. TAFURI AND M. TESTA. *Boll. soc. ital. biol. sper.* 3, 310-1(1928); cf. *C. A.* 22, 2954.—The total fatty extractive in follicular liquid by the Kumagawa-Suto Method was 0.110%. Total cholesterol by the Grigaut method was 0.002%. The difference between the 2 figures, 0.0487%, indicates the amt. of fatty acids in the liquid. The analysis for electrolytes made by the usual micro methods gave Na 0.301, K 0.0182, Ca 0.0051, and Cl 0.375%.

PETER MASUCCI

The presence of glucose in normal urine. G. QUAGLIARIELLO AND E. TRIA. *Boll. soc. ital. biol. sper.* 3, 311-3(1928).—Phenylosazones were prepd. from a large no. of normal urines by the following method: To 5 cc. of urine defecated with Hg or Pb(OAc)₂ or acidified with AcOH and treated with powd. charcoal, was added 1 cc. of a mixt. of 4 N AcOH-NaOAc (p_H 4.7) and a drop of C₆H₅NHNH₂ and placed on the water bath for 60-90 min. On cooling and standing, crystals were formed which on examn. microscopically differed in shape from those described by Patterson. They are also different from those obtained by treating 0.1% solns. of glucose by the same method. The latter are longer and are grouped in sheafs; the former are shorter and are grouped in rosetts. If, however, osazones are prepd. from very dil. solns. of glucose 1:10,000 then the crystals obtained are similar in every respect to those obtained from urine. The osazone from urine was centrifuged, redissolved, crystd., and repeatedly washed with Et₂O and dried. The m. p. was 261°. Conclusion. The phenylosazone obtained from normal urine does not differ in shape or m. p. from phenylglucosazone.

PETER MASUCCI

The buffer value of muscle juice and the isoelectric point of myoprotein. I. DE CARO. *Boll. soc. ital. biol. sper.* 3, 314-6(1928).—Frog muscle juice was used to det. 4 titration curves covering the range p_H 2-13. By means of the Bovie potentiometer curves were established for (1) fresh muscle juice, (2) the dialyzate, (3) the dissolved myoprotein and (4) that of 0.1 N NaOH against 0.1 N lactic acid. There is a definite parallelism between the curves. The buffer value is zero at the point where the individual curves cross the acid-base curve. Curve 1 crosses curve 4 at p_H 6.3; curve 2 crosses curve 4 at p_H 6.5; curve 3 crosses curve 4 at p_H 6.2. The lactic acid formed in the muscle during work is sufficient to bring the reaction of the muscle close to the isoelec. point p_H 6.2 of myoprotein.

PETER MASUCCI

The activity of the thyroid gland in relation to the staining reactions of the colloid. EVELYN E. HEWER. London School of Medicine for Women. *J. Path. Bact.* 30, 621-6(1927).—It is possible to gage the degree of activity of the stored thyroid secretion by the staining reactions of the colloid. Freshly secreted active material gives an alk. staining reaction, whereas old or inactive material is acid. The activity of a portion of a gland removed at operation is not always directly related to the basal metabolic rate. The staining variations depend on the acid-alk. reaction on the colloid, and not on its I content.

JOHN T. MYERS

Urinary elimination of ammonia and of total nitrogen. Urinary constants. R. RAFFLIN. *Bull. soc. chim. biol.* 10, 812-21(1928); cf. *C. A.* 22, 2614.—Nine logarithmic formulas for K_1 to K_9 are worked out showing relations of urinary p_H , ammonia N, total N, and hourly vol.

L. W. RIGGS

Action of an aqueous extract of nerve substance on the excitability of the nervous system. J. E. ABELOV'S AND H. LASSALLE. *Compt. rend.* 186, 1754-5(1928); cf. *Compt. rend.* 186, 1015.—An ext. of brain tissue was made by shaking 10 g. of cerebral pulp with 100 g. of physiol. serum, centrifuging and filtering through a Berkfeld filter. This ext. introduced into rabbits by the parenteral route shows a neurotropic excitatory action. Consequently the increase of nerve excitability in animals following a section

of the sciatic nerve is due to the resorption of nerve substance from the nerve trunk sepd. from its trophic center.

Presence of ergosterol in human blood. L. H. DEJEST, (MILLER) VANSTOLK AND E. DUREUL. *Compt. rend.* 187, 311-3(1928) --Ergosterol was sepd. from blood by the method of Lemeland (cf. C. A. 17, 3036), and identified by absorption bands situated at 2935, 2815 and 2700 Å. U. A study of the relation of the action of ultra-violet rays to the presence of ergosterol is in progress.

Excitation of the internal and external secretion of the pancreas by the same excitant after suprarenalectomy. E. GLEY AND R. HAZARD. *Compt. rend. soc. biol.* 99, 195-7(1928); cf. C. A. 22, 3446

Does the follicular hormone inhibit the action of the luteinic hormone? R. COURRIER. *Compt. rend. soc. biol.* 99, 224-5(1928). --In expts with rabbits the corpus luteum exerted its normal action on the uterus, notwithstanding the injection of a strong dose of folliculin.

Ammoniacal coefficient of the urine under different nitrogenous diets. MICHEL POLONOVSKI AND PAUL BOULANGER. *Compt. rend. soc. biol.* 99, 233-5(1928); cf. C. A. 22, 3199. --In passing from a mixed to a meat diet the p_{H} of the urine is lowered and also the ammoniacal coeff. Upon the addn. of urea, glycine or gelatin in amts. to contain equal quantities of N, to ordinary mixed diet the ammoniacal N was increased only with gelatin. This increase is attributed to the presence of S in the gelatin. The total N in each case was increased and the ammoniacal coeff. was decreased. Accordingly the addn. of N to the diet was without direct influence on the elimination of ammoniacal N, nor has the latter any direct relation to the p_{H} of the urine.

Calcium and magnesium content of muscular tissue of animals under thyroid treatment. M. CAHANE. *Compt. rend. soc. biol.* 99, 245-6(1928). --The total quantity of fresh thyroid gland administered varied from 4 to 40 g., and the duration of the treatment from 12 to 158 days. The tests were made with cats, dogs, rabbits and guinea pigs. There was a diminution of the Ca content of the muscles in 7 animals and an increase in the Ca content in 3 animals as compared with controls. Mg increased in 6 and decreased in 5 animals. The variations in Mg in no sense followed those of Ca. With much smaller doses of thyroid the Mg appeared to vary with the Ca.

Modifications of the chemical constitution of the blood during the experimental hyperthyroparathyroidian syndrome and in animals subjected to thyroid treatment. C. I. PARHON AND HILÈNE DEREVICI. *Compt. rend. soc. biol.* 99, 246-8(1928); cf. C. A. 22, 263. --In general hyperthyroidization increased the serum Ca and Cl and diminished the cholesterol and urea of the blood. Extirpation of the parathyroids during hyperthyroidization was generally followed by no marked change in the serum Ca, an increase in the serum cholesterol and urea and a decrease in the Cl. The diminution of the Ca of the blood is not the sole factor which causes *tetany* in animals deprived of parathyroids.

Histochemical demonstration of the formation of an aldehydic substance at the expense of aliphatic and lipoidic inclusions. JEAN VERNE. *Compt. rend. soc. biol.* 99, 266-9(1928). --The aliphatic or lipoidic inclusions contain substances of aldehydic function which are liberated in the course of fixation by PtCl_4 or HgCl_2 . These substances take part in the normal metabolism of the glycerides and phosphatides at the expense of which they appear to be formed by oxidation.

The presence of urea in the saliva; its relation to the blood urea. R. VLADESCO. *Compt. rend. soc. biol.* 99, 434-6(1928). Urea appears to be a const. constituent of the saliva of animals but is sometimes absent from the saliva of man. In man, N which is measurable by hypobromite is greater in the saliva than in the blood. The reverse is true in the dog, cat and horse. Ammoniacal N in the saliva of man is much greater than that of animals, but this may be due to differences in diln. caused by different methods of collection.

Hypophysary hormones in the guinea pig. ALEXANDER LIPSCHUTZ AND RAMON PAEZ. *Compt. rend. soc. biol.* 99, 453-4(1928); cf. Smith and Engel, *Am. J. Anat.* 40, 159; Zondek and Ascheim, C. A. 21, 763, 3942. --The precocious sexuality following injections of hypophysis ext. is observed in the guinea pig provided the exts. are from adult animals. Hypophysary hormones and law of puberty. ALEXANDER LIPSCHUTZ AND HELMUTH KALLAS. *Ibid.* 454-6. The results with guinea pigs were contrary to those of Smith and Engle with rats and mice in that the hypophysis from young guinea pigs was not able to initiate the sexual transformations which are caused by the hypophysis of adult animals.

Exocrine activity of the pancreas and islets of Langerhans. Case of hibernation. H. BIERRY AND MAX KOLLMANN. *Compt. rend. soc. biol.* 99, 456-9(1928).—Is the endocrine function of the pancreas localized uniquely in the islets of Langerhans? *Ibid* 459-60.—The islets of Langerhans appear to have a specialized function, but it is not proved that the acinian tissue is completely foreign to the metabolism of carbohydrates. In the normal condition there exists a morphological equil. between the acinian and endocrinian tissues of the pancreas. This equil. is broken by various states such as inanition, lack of factor B and hibernation. L. W. RIGGS

Calcium content in the organs of the rabbit. E. BARRAL AND PH. BARRAL. *Compt. rend. soc. biol.* 99, 519-20(1928).—The detn. of Ca by incineration of the tissue, extn. of the ash with HCl, pptn. as oxalate and titration by permanganate was considered sensitive within 0.5 mg. The Ca content of the muscles and organs of different rabbits ranged from 3 to 160 mg. per kg., and from 6 to 160 mg. in the same organ of different animals. Increase of the calcium content in the organs of rabbits given doses of naphthalene. A. CADÉ AND PH. BARRAL. *Ibid* 520-2.—While precise conclusions were not drawn, it was evident that there was a general tendency toward an increase in the Ca content in the organs of rabbits receiving naphthalene. L. W. RIGGS

Reversible crystallization in tendons and its functional significance. JANET H. CLARK. *Proc. Nat. Acad. Sci.* 14, 526-32(1928).—X-ray pin-hole diagrams with fresh moist tendons and ligaments show that collagen and elastin exist normally in liquid crystal form but that collagen undergoes a reversible crystn. in tendons when they are stretched. The formation of solid crystallites in a stretched tendon probably increases its cohesion and marks the limit of its elasticity. L. W. RIGGS

An interpretation of excitation, exhaustion and death in terms of physical constants. G. W. CRILE, AMY F. ROWLAND AND MARIA TELKES. *Proc. Nat. Acad. Sci.* 14, 532-8 (1928).—Expts. on 100 rabbits have indicated the following conclusions in regard to the p. d. in living tissues: (1) Excitation or stimulation produced by phys. injury, drugs or other agents causes an immediate fall in the p. d., followed by a rise. Repeated or protracted excitation tends to diminish the p. d.; and when the p. d. approaches zero, death occurs. (2) Anesthetics, narcotics, hemorrhage and asphyxia diminish the p. d. progressively until as it approaches zero death occurs. (3) After death there is a secondary rise of p. d. in the brain and in voluntary muscle. (4) Consciousness and activity apparently are maintained at the expense of p. ds. (5) Sleep appears to be necessary to maintain a continuous p. d. in the brain, as prolonged insomnia progressively diminishes the p. d. between the fascia and the brain. (6) The thyroid gland is necessary for the maintenance of a normal p. d., for in myxedema the p. d. is diminished nearly to zero. (7) The life of an organism exists only as long as p. ds. are maintained within the organism. L. W. RIGGS

New study yields first published analyses of horses. H. H. MITCHELL AND T. S. HAMILTON. *Illinois Agr. Expt. Sta. Rept.* 1927, 119-21.—The only abs. measure of an animal's requirements for nutrients is the amt. of nutrients actually built up into its own tissues. In this work the carcasses of 3 Percheron horses of different ages were analyzed. The live wts., skin areas and % of "fill" are given, and on the empty wt. basis the % of flesh, bone, blood, hide and viscera of the carcass. The wt. in g. of several of the visceral organs including the liver, kidneys, spleen, lungs, heart, brain, testicles and alimentary tract and the chem. compn. of the blood, flesh and bone samples and of the entire carcasses minus the contents of the intestinal tract are summarized. By analyzing a large no. of Percheron horses varying in age it is hoped eventually to be able to plot curves of increasing wts. of protein, Ca, energy, etc., with age, from which may be computed the daily increment in nutrients during normal growth. E. F. SNYDER

Changes in the composition of protoplasmic tissue caused by partial starvation. A. G. HOGAN AND W. S. RITCHIE. *Missouri Agr. Expt. Sta., Bull.* 256, 31-2(1927). cf. C. A. 22, 2400.—The most satisfactory method of extg. muscle proteins has been repeated extn. with 10% NaCl. Three methods of pptg. the globulin fraction have been selected and within fairly narrow limits gave good agreement as shown in a table. The exposure to ultra-violet rays was the least satisfactory, probably because the factor of H-ion concn. and of temp. were not sufficiently standardized. E. F. S.

Blood chemistry of the albino rat. ARTHUR K. ANDERSON AND HANNAH E. HONEYWELL. *Penn. Agr. Expt. Sta., Bull.* 213, 7(1927).—With a view to future work on the blood of abnormal or pathol. animals, a study has been started on the compn. of the blood of the albino rat. Non-protein N, urea, creatinine, creatine, uric acid, chlorides and glucose have been detd. Values for some constituents differ from normal

human averages. Non-protein N and urea values are slightly higher than for human blood.

E. F. SNYDER

The role of potassium in cell growth. A. LASNITZKI. *Z. Krebsforsch.* **27**, 115-24 (1928).—K increases the intensity of cell growth, and analyses of growing tissues show an increased K content parallel to the intensity of growth activity, with which also goes a parallel increase in the water content of the cells. The increase in water is dependent on an increase of the hydration of some or all of the cell colloids, which depends upon the K content. Fermentation of glucose to lactic acid is the energy-producing reaction of cell growth. The fermentative action of the cells in general increases with general increased intensity of growth. The K in the cells increases fermentative activity. The intensity of the reactions which furnish energy for cell growth is dependent on a specified sort of hydration swelling of certain colloids of the cells, in such a way that it increases with increasing hydration of these colloids within certain limits provided that all other factors bearing on the energy-producing reactions remain constant. Under normal conditions regulation of this hydration is detd. by the K.

H. G. WELLS

G—PATHOLOGY

H. GIDEON WELLS

Excretion of hippuric acid in renal disease. I. SNAPPER AND A. GRÜNBAUM. *Presse med.* **34**, 1524-6 (1926).—Oral administration of 5 g. of Na benzoate to healthy men res: Its in 12 hrs. in its quant. excretion as hippuric acid. In renal disease with N retention the excretion (but not the formation) is incomplete.

B. C. A.

Chemistry of specific hemagglutination. A. KONIKOV. *Zhurnal expl. biol. med.* **1926**, 124-45.—The erythrocytes can be regarded as an amphoteric protein of isoelec. point p_{H} 5. Probably only between p_{H} 6 and 9 are the stroma and agglutinin oppositely charged. The presence of electrolyte is necessary in the first phase of hemagglutination, the action of the salt is expressed by the scheme stroma—Na—Cl—agglutinin, in which auxiliary valencies function.

The subject is discussed from this point of view.

B. C. A.

Ultramicroscopic investigations on the crystalline lens. IV. Modification of the ultramicroscopic structure in the process of cataract. D. CATTANEO. *Atti. accad. Lincei* [6], **7**, 512-6 (1928); cf. *C. A.* **22**, 1182.—The same ultramicroscopic method used before for the normal eye was used in the present investigation. In all cases of cataract, the greatest alterations were in the lenticular fibers, while the condriosomes diminished or disappeared, and the protoplasmic colloids showed various changes, including granulation resulting from pptn. of the colloids. In conjunction with earlier work of C. and others, the expts. lead to the conclusion that cataract involves a transition from a homogeneous system to a heterogeneous system by pptn. of granules or droplets of the proteins which constitute the fundamental protoplasm. The same effect may be induced artificially by acids, heat, etc. •

C. C. DAVIS

The coenzyme of glucolysis from tumors. HEINRICH KRAUT AND ERWIN BUMM. Bayer. Akad. Wissensch. Munich. *Z. physiol. Chem.* **177**, 125-42 (1928).—Tumors contain an abundance of coenzyme which activates glucolysis by kidney tissue. Exts. prepd. by grinding carcinomas and sarcomas with quartz sand and 5-10 parts of H_2O , centrifuging and filtering, do not form acid from glucose in Ringer soln. If to the mixt. is added a section of kidney from which the coenzyme has been removed by washing, a vigorous glucolysis takes place. The effect is several times as great as that produced by a similar ext. from the same amt. of kidney tissue. The tumor ext. alone does not undergo glucolysis; hence it contains no active glucolytic enzyme. Since the ext. rapidly loses its activating effect on glucolysis by normal tissue, either by destruction of the coenzyme through autolysis or by bacterial decompn., it is preferable to obtain dry preps. by treatment of the fresh tissue with MeAc and Et_2O and then make the extn. by means of 0.01 N NH_4OH . A 2 hr. extn. gives the most active solns.; longer extn. is unsatisfactory because the coenzyme is then contaminated with inhibitory substances. A 2nd extn. gives almost as good a yield as the 1st. Addn. of 8 vols. $EtOH$ to the NH_4OH ext. ppts. a white flocculent mass which contains the entire activity but only $\frac{1}{4}$ of the dry matter of the ext. From solns. of the $EtOH$ ppt. the coenzyme may be adsorbed on kaolin or alumina. The latter is the better adsorbent for dil. solns., the former for concd. solns. The inhibitory substance does not act by binding the coenzyme. It is best removed by alumina adsorption. Whether this inhibitory substance is identical with that of cozymase is not certain. Unlike

the latter it is not destroyed more rapidly by heating than the coenzyme. It is not known whether it exerts its function in the living cell or whether it is first set free in the exts. Certain it is that the coenzyme constitutes the limiting factor for glucolysis in the normal epithelial tissue of liver and kidney, and that the carcinoma tissue is distinguished from these by its higher content of coenzyme. The coenzyme content of the exts. increases in the order: liver, kidney, embryo, tumor. The glucolysis of the individual tissues decreases in the same order.

A. W. DOX

Chemistry of the normal and atherosclerotic aorta. RUDOLF SCHÖNHEIMER. Univ. Freiburg. *Z. physiol. Chem.* **177**, 143-57(1928); cf. *C. A.* **21**, 417.—Sep. analyses of the highly calcified and the non-calcified portions of the atherosclerotic aorta show no essential differences in the free cholesterol and the cholesterol ester content. Evidently the lipid mixt. is formed elsewhere and deposited as such. The hypothesis according to which the deposit of Ca is caused by the free acids formed during hydrolysis of cholesterol esters should be rejected. The proportions of CaO , P_2O_5 , and CO_2 in the atherosclerotic aorta correspond approx. to those present in bone. Free cholesterol, cholesterol oleate, stearate and palmitate and a galactoside similar to protagon were isolated. Two doubly unsatd. cholesterol esters and an unsaponifiable substance not pptd. by digitonin were also demonstrated. Neutral fats appear to be absent.

A. W. DOX

The chemical composition of the active principle of tuberculin. XI. An improved and simplified method for making a standard undenatured tuberculin of any desired strength and a method of chemical assay. FLORENCE B. SEIBERT. Univ. of Chicago. *J. Biol. Chem.* **78**, 345-62(1928); cf. *C. A.* **22**, 2197.—A virulent human strain of tubercle bacilli is planted upon a Long non-protein synthetic medium and allowed to incubate for 3 months. The bacilli are then completely removed through a Berkefeld filter. The filtrate of tuberculin, preserved with 0.5% phenol, is concd. to any desired strength by ultra-filtration through alundum extn shells previously impregnated with a 10 to 12% soln. of sol. guncotton in glacial AcOH and washed free of all acid. The speed of filtration may be accelerated tenfold by using membranes of an 8% soln. of guncotton or parlodion in glacial AcOH . The tuberculin is standardized by detg. the amt. of ppt. obtained when CCl_3COOH is added to a standard amt. of tuberculin. By this chem. standardization it was revealed that any tuberculin prepn. increases in potency with age of the culture up to at least 3 months incubation.

RUSSELL C. EBB

Chemical changes in the body occurring as the result of vomiting. A. F. HARTMANN AND F. S. SMYTH. *Am. J. Diseases Children* **32**, 1-28(1926); *Physiol. Abstracts* **11**, 476.—A study of the blood in 20 cases of vomiting due to various causes showed that chloride is lost and bicarbonate retained in compensation; if the lost chloride is not fully replaced by bicarbonate the non-protein N is elevated to maintain the normal osmotic pressure. When the NaHCO_3 content of the blood is high, respiration is depressed, and carbonic acid accumulates so that the p_{H} of the blood is normal; increased pulmonary ventilation then makes the blood abnormally alk., and tetany may result. The excess of non-protein N and NaHCO_3 is excreted as a result of administration of NaCl ; but the excretion of all three depends on the total crystalloid concn. in the blood; if this is below normal, NaHCO_3 is retained in the blood and the urine remains acid in spite of the increased plasma CO_2 content.

H. G.

Chemical changes occurring in the body as the result of certain diseases. I. The effects of diarrhea, vomiting, dehydration and oliguria on the acid-base balance of the plasma of infants with mastoiditis. ALEX F. HARTMANN. Washington Univ. School of Med. *Am. J. Diseases Children* **35**, 557-75(1928).—The chem. changes which occur in the blood during mastoiditis are the result of physiol. disturbances assoc. with the infection. These disturbances, which may be caused by the absorption of toxic products from the focus of the infection, are: vomiting, diarrhea, dehydration and oliguria. Vomiting produces a reduction in the HCl and base chloride reserve; dehydration, an increase in the lactic acid and protein concns. in the blood plasma; and oliguria, an increase in the phosphoric acid and non-protein N concns. E. R. M.

Liver function tests. JOSEPH S. HEPBURN AND H. M. EBERHARD. Hahnemann Med. Coll., Philadelphia. *Hahnemannian Monthly* **63** 605-23(1928).—A discussion of the measurement of liver function by means of (1) halogenated dyestuffs of the aromatic series, (2) the icteric index, (3) the van den Bergh test and (4) the hemoclastic crisis of digestion. The technic of each test is described. A series of 19 cases of various liver diseases is reported to illustrate the use of these tests in diagnosis and in following the progress of a case under treatment, and to ascertain their agreement with each other before the beginning of treatment. Throughout the entire series of 19 cases, on the

before and after operations is emphasized. Alkalemia is usually assocd. with clinical symptoms, such as tingling and numbness of extremities, headache and nausea, which hitherto have been considered as functional. In 19 miscellaneous cases (gastric carcinoma, severe diarrhea, pernicious anemia, chronic nephritis, etc.) similar changes in the blood have been observed.

MARY JACOBSEN

Extrahepatic formation of bilirubin. R. SOEJIMA. *Arch. klin. Chir.* **149**, 206-12 (1927); *Ber. ges. Physiol. exptl. Pharmacol.* **44**, 646.—Wound secretions contain a bilirubin, which differs from serum bilirubin by its soly. in CHCl_3 . Its local formation from hemoglobin was confirmed exptly. in hematomas. *In vitro* the formation takes place on contact of blood with air and is hastened by germs from the air. In Banti's disease the bilirubin content of the splenic venous blood considerably exceeds that of the arterial blood. Injections of hemolyzed blood into normal spleen cause formation of bilirubin. Splenectomy reduces the sensitiveness of dogs to PhNHNH_2 . The soly. in CHCl_3 of bilirubin of local hemolytic origin may be used for the differentiation between hepatic and biliary obstruction jaundice. It is pointed out that the theory of the exclusively hepatic origin of bile pigments is definitely disproved.

MARY JACOBSEN

Are the urine toxins detoxified by the liver? HARTWICH. *Verh. deut. Ges. inn. Med.* **1927**, 172-7, 181; *Ber. ges. Physiol. exptl. Pharmacol.* **44**, 645.—Brücke has connected a ureter with the iliac vein in order to elucidate the causes of hypertrophy of the kidney in unilateral nephrectomy. His animals died rapidly from uremia. H. transfused the urine of one kidney into the portal and mesenteric superior veins. The animals died from uremia as soon as the blood urea reached 10 times its normal value, but they lived longer than H.'s animals. The liver which showed fatty degeneration apparently had a certain detoxifying effect.

MARY JACOBSEN

The surface tension of the blood plasma in children. ESTHER B. CLARK. Stanford Univ. School of Med. *Am. J. Diseases Children* **35**, 18-25(1928).—The surface tension observed in 87 samples of blood plasma, as measured by a modification of the DeEds method, was 52 ± 5 dynes per cm. Lower values were found in kidney disease assocd. with plasma lipemia; slightly higher values in rheumatic fever, chorea, endocarditis and in fever; and normal ones in allergy. The surface tension of blood plasma appeared to be higher in girls than in boys and to be influenced by age. E. R. M.

Effect on the urine of addition of acids and alkalis to the diets of infants. DAVID GREENE. Home for Hebrew Infants, N. Y. *Am. J. Diseases Children* **35**, 38-46 (1928).—The addn. of acids to the milk diets of infants, as is frequently carried out in order to decrease the buffer action of the milk on the gastric juice, may occasion pathol. changes in the urine. The addn. of Ca lactate, lactic acid or 0.1 N HCl to milk diets may cause the appearance of casts or red blood cells. The administration of lemon juice in a concn. of 3% causes no unusual effects. Alkalis, such as 0.1 N NaOH or NaHCO_3 , may produce an alk. reaction in the urine, but appear to produce no other pathol. effects.

E. R. MAIN

The sex factor in infantile tetany. HARRY BAKWIN AND RUTH MORRIS BAKWIN. Columbia Univ. *Am. J. Diseases Children* **35**, 964-7(1928).—The incidence of infantile tetany appears to be greater in boys than in girls. Among the 136 cases observed, boys were affected more than twice as often as girls and were apt to have the disease in a more severe form. The Ca content of the blood serum was the same for both sexes.

E. R. MAIN

Further notes on the spontaneous agglutination of bacteria. P. BRUCE WHITE. Lister Inst., London. *J. Path. Bact.* **31**, 423-33(1928).—Stability of a bacterial suspension in an aq. medium depends on the dominance of the hydrophile factors of the bacterial surface over those which are hydrophobic: that is, on a hydrated or sol state of the bacterial surfaces, by which continuity between the medium and the particles is established. Instability depends on the opposite condition of a sharp discontinuity between the phases. In fresh cultures alc.- CHCl_3 -sol. lipids form the important hydrophobic factor. In normal smooth cultures such as those of the colon-Salmonella group, the aggregating influences of these substances in the presence of electrolytes are completely counterbalanced by the "sol. sp. substance" of the bacterial bodies, which is insensitive to electrolytes and acts powerfully for the permanence of suspension. In rough cultures, the disappearance of the sol. sp. substance allows the lipids to overwhelm the hydrophile properties of the basal body proteins, causing agglutination in a saline medium. If the lipids are removed stable emulsions result. In some organisms, as certain streptococci, the amt., or hydrophobic activity, of the lipids is so great that the normal smooth colony is salt agglutinable and may fail to form stable suspensions even in distd. water. When bacterial suspensions are heated

to 100° the body proteins are denatured, in the rough colony this means increased agglutinability by electrolytes; in the smooth colony response to electrolytes is prevented by the action of the unchanged sol. sp. substances. Unsp. agglutination by serum in the case of some strains is due to lipoids peculiar to the strain, which cause pptn. through a particular range of serum dilns. Lipoid extn. removes the agglutinability. The sol. sp. substance of the smooth colonies is heat stable, non-antigenic on animal inoculation, and reacts precipitatively in a manner exactly correlated with the agglutinative reaction of the bacterial soma from which it is derived. Alk. lysates of smooth colonies contain substances antigenically identical with the body substance of the rough colony.

JOHN T. MYERS.
 Relativity applied to biologic problems. J. TIXIER. *Bull. sci. pharmacol.* **35**, 423-5(1928); cf. *C. A.* **22**, 2957.—In 4 normal persons the ratio (multiplied by 10,000) of uric acid/fixed elements in the urine was represented by figures ranging from 60 to 86. In 4 syphilitic cases the corresponding range was 116 to 169. L. W. RIGGS

Sugars of the blood and of the plasma. Proteinic sugar. H. BIERRY. *Bull. soc. chim. biol.* **10**, 769-77(1928).—The subject is reviewed with 29 references to the literature. The existence of proteinic sugar in the plasma is established beyond doubt. Its physiologic and pathologic variations observed along with those of free sugar show its importance. The inventory of plasma sugars should include both the free sugar and the proteinic sugar, as in certain pathologic cases the latter may be 3 or 4 times greater in quantity than the former. The variations in the proteinic sugar may sometimes account for the variations in the free sugar. L. W. RIGGS

Passage of the antibodies of the blood into the cerebrospinal fluid. L. STERN, G. N. KASSIL, E. S. LOKSHINA, E. L. ROMEL AND S. M. ZEITLIN. *Compt. rend. soc. biol.* **99**, 360-2(1928).—In normal cats and rabbits neither natural nor artificial hemolysins were found in the cerebrospinal fluid. Hemolysins were found in the cerebrospinal fluid after the following treatments. chronic poisoning by illuminating gas, severe acute poisoning by alc., the administration of 0.5 to 1.0 g. per kg. of urotropine. diphtheritic intoxication during the hypothermic phase but not during the hyperthermic phase, chronic blockage of the recitulo-endothelial system by repeated intraperitoneal injections of India ink, elevation of body temp. above 41° or depression below 36°, changing the osmotic pressure of the blood by hypertonic or hypotonic injections, increasing the p_H of the blood by injections of NaHCO_3 or decreasing the p_H by injections of NaH_2PO_4 . Influence of changes on the p_H of the blood on the functioning of the hemato-encephalic barrier. L. STERN, E. L. ROMEL AND C. A. GUERTCHIKOVA. *Ibid* 363-4.—Deviation either way from the normal p_H of the blood is accompanied by a decrease in the resistance of the hemato-encephalic barrier to the passage of various substances. Influence of changing the osmotic pressure of the blood on the functioning of the hemato-encephalic barrier. L. STERN, S. M. ZEITLIN AND R. M. GOZMAN. *Ibid* 365-7.—Increasing the osmotic pressure of the blood above $\Delta = 0.8$, or decreasing the osmotic pressure below $\Delta = 0.45$ increases the permeability of the hemato-encephalic barrier. Influence of changes of temperature of the body on the functioning of the hemato-encephalic barrier. L. STERN, G. N. KASSIL AND E. S. LOKSHINA. *Ibid* 448-51. Effect of anaphylaxis on the functioning of the hemato-encephalic barrier. *Ibid* 451-2.—It is only in cases of well-marked anaphylaxis that a diminution of the resistance of the hemato-encephalic barrier to the passage of certain colloids such as trypan blue and Congo red is observed. In this case neither hemolysins nor crystalloids are found in the cerebrospinal liquid. L. W. RIGGS

Hyperglucemic action of the blood of the diabetic dog. Effects of transfusion of normal blood and of diabetic blood into animals carrying a pancreatic graft. L. KEPINOV AND S. PETIT-DUTAILLIS. *Compt. rend. soc. biol.* **99**, 481-4(1928); cf. *C. A.* **22**, 2105.—By transfusion of diabetic blood into a depancreated dog carrying a pancreatic graft and having a normal glucemia, a permanent hyperglucemia was developed, which was sensitive to the injection of insulin and resembled true diabetes. Attempt to extract hyperglucemic substances from diabetic blood. *Ibid* 484-6. L. W. R.

Fluctuations in the hydrogen-ion concentration of saliva in epilepsy. A. M. SAUNDERS. *J. Am. Med. Assoc.* **91**, 244-5(1928).—The samples of saliva were taken at 15-min. intervals with uniform precautions of rinsing the mouth and taking nothing into the mouth during the period of testing which lasted 5 or 6 hrs. The saliva of epileptics had a much wider range of variation (5.8 to 7.3) than that of normal persons (6.6 to 7.1). The abruptness and sudden wide range of the fluctuations was very evident in grave cases. L. W. RIGGS

Serological differentiation of steric isomers. K. LANDSTEINER AND J. VAN DER SCHUER. Rockefeller Inst. Med. Research. *J. Expil. Med.* **48**, 315-20(1928).—

l- and *d*-Phenyl(*p*-aminobenzoylamino)acetic acids were diazotized and coupled with proteins (*l*- and *d*-antigens); *l*- and *d*-immune sera were obtained by immunization with these azoproteins. The data presented show that only in the higher concns. cross reactions do take place and that there is definite specificity of the 2 sorts of immune sera for the homologous antigens. It is easy to differentiate the *l*- and *d*-antigens in dilns. 1:100 and upward. The occurrence of cross reactions can readily be ascribed to the fact that the *l*- and *d*-acids present in the 2 antigens are identical in every respect but the position of the groups connected with the asymmetric C atom. The *dl*-antigen react with both sorts of immune sera as could be expected since it must consist of a mixt. of equal parts of *l*- and *d*-antigen. The reactions of the *dl*-antigen appear to be only slightly weaker than those of the homologous ones because of the fact that the intensity of the reactions diminishes but slowly with increasing diln. of the antigens. The *d*- and *l*-immune sera also differentiate clearly between the *l*- and *d*-acids when not combined with proteins. The *l*-acid inhibits much more the pptn. of the *l*-antigen by the homologous immune serum than the *d*-acid and the converse effect occurs if the inhibiting action is tested on the pptn. of *d*-antigen by *d*-immune serum. C. J. W.

Chemical changes in the blood of the dog in experimental peritonitis. THOMAS G. ORR AND RUSSELL L. HADEN. Univ. of Kansas. *J. Exptl. Med.* **48**, 339-42(1928).—The changes noted in the blood chlorides, urea N and non-protein N resemble those observed in pyloric and high intestinal obstructions. In those 2 conditions an alkalosis develops which is not observed in general peritonitis. It thus seems probable that the cause of death may be somewhat similar. C. J. WEST

Effect of oxidation of filtrates of a chicken sarcoma (chicken tumor I-Rous). J. HOWARD MUELLER. Harvard Univ. Med. School. *J. Exptl. Med.* **48**, 343-9(1928); *Science* **68**, 88-9.—The rapid autoinactivation at 37° of candle filtrates of the Rous fowl sarcoma I is due in large part to oxidation. Such oxidation may be prevented by a diln. of 1-2000 cysteine-HCl brought to pH 7.4 with NaOH. C. J. WEST

Reactions of tissues. I. Hydrogen-ion concentration of tissues during fever. JUNTARO OGAWA. Univ. of Tokyo *Proc. Imp. Acad. (Japan)* **3**, 699-701(1927)—Injection of *Leptospira icterohemorrhagiae*, *icteroides* and *hebdomadis*, coli and typhus vaccines and tetrahydro- β -naphthylamine in aq. emulsion, into the rabbit, guinea pig, rat and mouse or overheating the animal at 40-1° and subsequent detn. of the pH values of the tissues of various organs, shows that there is a decrease in the normal value of 7.0-7.3 to 6.7-6.9. C. J. WEST

Tryptophan reactions in the spinal fluid. BURNHAM S. WALKER AND FRANCIS H. SLEEPER. *J. Lab. Clin. Med.* **12**, 1048-52(1927).—Tryptophan has been demonstrated as varying in intensity with the amt. of protein present in spinal fluids and in egg albumin solns. of known protein content. This relationship is not strictly quant., as a result of varying tryptophan content and of the presence of interfering substances in varying quantity. The Boltz reaction is dependent upon the tryptophan present in the protein mol. and may be of value in estimating increases in the protein content of spinal fluid, although it cannot be considered as sp. for any single clinical entity. E. W. W.

II PHARMACOLOGY

A. N. RICHARDS

Higher toxicity of methanol in presence of ethyl alcohol. M. PANTALEONI. *Ann. Iggiene* **37**, 537-40(1927).—A mixt. of equal parts of MeOH and EtOH is much more toxic to cats than either alc. alone. B. C. A.

Does adrenaline act through calcium? L. JENDRASSIK AND A. CZIKE. *Klin. Wochschr.* **6**, 1521(1927), cf. Jendrassik and Antal, *Ibid* 1338.—Zondeck's theory of parallelism between the action of adrenaline and Ca ions is unsupported by expt. B. C. A.

Chemical factors which determine the fixation of colloids. G. SPAGNOL. *Ann. attad. Lincei* [6], **7**, 667-9(1928).—The expts. are a continuation of earlier expts. in the same field (cf. C. A. **22**, 452). Expts. showed that when CHCl₃, CCl₄ or Et₂O is applied to the skin of rabbits, and a colloid such as eosin, nigrosin or other electronegative dye is then injected intravenously, the tissues underly those to which CHCl₃ has been applied fix the dye, and only these tissues. On the other hand, electropositive dyes, such as methylene blue, under the same conditions are not fixed. The results are of importance in pharmacology and therapy because they show the possibility of controlling the fixation of therapeutic agents, in the location desired, by the use of other reagents. The phenomenon is not confined to treatment of the skin with CHCl₃ or other anesthetic, for its application to muscle, vesicles and the peritoneum has a similar

influence on the fixation of dyes. This fixation of colloids may depend upon an increase in the permeability of the blood capillaries.

The effect of insulin on the sugar content of erythrocytes, including a comparison of the direct and indirect methods of measurement. HARRY C. TRIMBLE AND STEPHEN J. MADDOCK. Harvard Med. School. *J. Biol. Chem.* **78**, 323-36(1928).—In expts. upon diabetic patients and normal and diabetic dogs, no indication is found that insulin causes a sudden and marked drop of sugar in the erythrocytes preceding that in the plasma or whole blood. The rate of sugar decrease in man is about uniform in all portions of the blood. The direct method of detg. sugar in erythrocytes after their sepn. from plasma gives results as reliable as those with the indirect method, *i. e.*, computation based on whole blood and plasma sugar and the vol. percent of erythrocytes. As the latter method may misrepresent the situation it should be employed with the first method as a check. Insulin has only a very slight effect on the concn. of non-fermentable reducing substances in blood.

A liver extract (pernämön) for the treatment of pernicious anemia. ERNST LAQUER AND A. P. W. MÜNCH. Univ. of Amsterdam. *Deut. med. Wochschr.* **54**, 951-2 (1928).—Five liver exts., prepd. by different processes, were analyzed and found to be essentially the same in compn. *Pernamon*, one of these preps., had an excellent therapeutic effect in pernicious anemia.

Chemotherapy. II. Chemotherapy of bacterial infections. R. SCHNITZER. Koch Inst., Berlin. *Deut. med. Wochschr.* **54**, 878-9; 1001-2(1928), cf. *C. A.* **21**, 611.—A review with 116 references to the literature.

Results of chemotherapy in pediatric practice. DE RUPDER. Univ. Kinderklinik, Würzburg. *Deut. med. Wochschr.* **54**, 1083-5(1928).—Quinine, arsphenamine and its derivs., and certain of the acridine dyes are considered as the only potent chemotherapeutic agencies useful in pediatrics.

Pharmacology of allylisopropylacetylcarbamide (sedormid). V. DEMOLE. *Deut. med. Wochschr.* **54**, 1166(1928).—Isopropylallylacetylcarbamide is a mild, safe sedative and soporific which is rapidly destroyed in the body and has no deleterious cardiac or renal effects.

Salabrose and its use in diabetes. FR. FRIEDRICHSEN. *Deut. med. Wochschr.* **54**, 1294-5(1928).—Salabrose, a deriv. of sugar, was found to be of great value as a nutrient and preventive of ketonuria in diabetics.

The influence of the administration of aluminum upon the aluminum content of the tissues of the dog. VICTOR C. MYERS AND D. B. MORRISON. State Univ. of Iowa. *J. Biol. Chem.* **78**, 615-24(1928).—The normal Al content of the visceral organs of the dog varies between 0.07 and 0.15 mg. per 100 g. The daily ingestion of 1.55 g. of Al for 3 months led to no increase in the Al content of the organs, except the liver and the bile where it averaged 27 mg. and 0.35 mg. per 100 g., resp. After parenteral administration, there is a marked increase in the Al content of the tissues even after 34 days.

The effect of sodium citrate, acetate and lactate on the ultrafilterability of serum calcium. D. H. SHELLING AND H. F. MASLOW. Jewish Hospital, Brooklyn. *J. Biol. Chem.* **78**, 661-9(1928).—The biological action of Na citrate, acetate and lactate is correlated with the effect of these substances on the filterability of the Ca^{++} . Na citrate produces convulsions when injected and increases the filterability of the serum Ca. Na acetate and lactate on the other hand neither produce convulsions nor do they affect the filterability of the Ca^{++} .

Clinical calorimetry. XLII. A comparison of the effect of glucose and dihydroxyacetone on metabolism. W. S. McCLELLAN, A. BIASOTTI AND R. R. HANNON. Russell Sage Inst. Pathology, N. Y. *J. Biol. Chem.* **78**, 719-44(1928).—Dihydroxyacetone caused a rapid elevation in the respiratory quotient and approx. the same specific dynamic action as glucose. After the ingestion of 50 g. of either hydroxyacetone or acetone by normals or diabetics, there was no increase in the acid phosphomolybdate reducing substances of the blood and only a slight increase in the concn. of these substances in the urine after the ingestion of dihydroxyacetone. The blood sugar curves of normals showed a fall 1 hr. after the ingestion of 50 g. of dihydroxyacetone while in diabetics there was a rise which was less marked than after glucose ingestion.

Influence of intravenous and peroral administration of sodium bicarbonate on tetanus. PAUL HELM. *Klin. Wochschr.* **7**, 794-5(1928).—Administration of NaHCO_3 relieves the spastic condition in tetanus. Complete cures have been effected in a small no. of children.

Action of buffer solutions on gastric secretion. J. VANDORFV AND E. BARATH.

Klin. Wochschr. 7, 800-2(1928).—It is possible by administering phosphate buffer solns. of pH 7.18 to 7.54, to control hyperacidity in patients afflicted with gastric disturbances. The buffer solns. do not irritate the gastric mucosa. They neutralize excess acidity and do not call forth an after-flow of HCl as is the case with $NaHCO_3$.

MILTON HANKE

Effect of diuretics on the excretion of substances into the cerebrospinal fluid and into the intraocular fluid. A. FRANCESCHETTI and P. H. WIELAND. *Klin. Wochschr.* 7, 876-8(1928).—Arsenic can be detd. in the cerebrospinal fluid, the intraocular fluid and in the cornea after administration of Sulfomesarca. Theophyllin, injected simultaneously, leads to an increased excretion of As into the areas cited above. M. H.

Clinical observations in lead poisoning. J. G. GELMAN. *Arch. Hyg.* 96, 301-10 (1926).—The following method is given for the detn. of small quantities of Pb: the solid material is dried, powd. and ignited gently in a crucible of pure Ni. If not easily ignited, it is first moistened with $NaNO_3$. The ash is transferred to a beaker, dissolved in HNO_3 , and the mixt. boiled and filtered. The filter is dried, and the residue fused in a Pt vessel with Na_2CO_3 , K_2CO_3 , and KNO_3 . The melt is then dissolved in H_2O , the mixt. filtered to remove Fe, the filtrate acidified with HNO_3 and added to the first filtrate. $NaOH$ is added till the soln. is cloudy, then HCl till it is just clear. The Pb can now be pptd. quantitatively with H_2SO_4 . The most striking effect of Pb poisoning is upon the blood, and anemia is the earliest symptom. Pathol. changes are observed in the nervous system, the parenchymatous organs, and the blood vessels. The nature and extent of the symptoms vary widely in specific cases. P. Y. J.

Cardiazole. Some experimental effects of this drug on the cardiorespiratory mechanism. M. HERBERT RAKER and SAMUEL A. LEVINE. Harvard Medical School. *Arch. Internal Med.* 42, 14-22(1928).—"In a series of expts. on cats it was found that cardiazole did not have any beneficial effect on the cardiorespiratory mechanism. This was true in the normal animals and in states of depression, produced by quinidine, hemorrhage and acid intoxication" (intravenous injections of 2-10 cc. 0.5% H_2SO_4).

MARY JACOBSEN

Tolerance for quinine in exophthalmic goiter. ISRAEL BRAM. *Arch. Internal Med.* 42, 53-5(1928); cf. *Bram, N. Y. Med. J.* 118, 339(1923); Sainanton and Schulman, *Bull. mem. soc. med. hop. Paris* 45, 1304(1921); Pfahler, *Med. Clin. N. America* 5, 854(1921).—Patients with exophthalmic goiter may take 1.0 g. quinine-HBr or quinine- H_2SO_4 daily for a period of months without exhibiting cinchonism. The treatment often results in clinical improvement and reduction in the size of the thyroid. The appearance of intolerance is mostly a sign of recovery and is assocd. with normal basal metabolism. The Bram test was found to be very useful by Pfahler and of no value by Sainanton and Schulman. B. finds an av. error of 4.4%. MARY JACOBSEN

The reducing substances of the blood in lead poisoning. A. MITTLESTEDT. *Moskovskij med. zhurnal* 7, 1-4(1927); *Ber. ges. Physiol. exper. Pharmacol.* 44, 667.—The reducing substances of the blood (Hagedorn) vary within narrow limits in fasting dogs or dogs fed on milk and meat. The content rises sharply from 80 to 120 mg./100 cc. in the 1st hr. after bread feeding and remains at this level for 6-7 hrs. In acute Pb poisoning (0.5 g. $Pb(OAc)_2$ daily for 22 and 5 days, resp.) no deviation from the normal was observed. In the following chronic stage the increase caused by bread is greater and more persistent than in normal dogs. Normal values are gradually reached in the remission period.

MARY JACOBSEN

Hypoglycemic properties of galegine sulfate. H. SIMONNET and G. TANRET. *Bull. soc. chim. biol.* 10, 796-805(1928).—The results of this study are shown in 10 tables. Doses of about 4 mg. per kg. of galegine sulfate cause a lowering of the glucemia in healthy dogs and man which may reach 20%. Galegine sulfate also causes a lowering of the glucemia and the glucosuria in depancreated dogs. Also in *Compt. rend.* 185, 1616-7(1927).

L. W. RIGGS

Cardiovascular action of tropinone. RENÉ HAZARD. *Compt. rend.* 186, 1752-3 (1928); cf. *C. A.* 19, 3323; 20, 1114, 1278; 21, 776, 1845.—Tropinol and tropinone may be considered the inferior homologs of *N*-methylgranatoline and pseudopelletierine, resp. The object of this study was to compare the cardiovascular action of tropinone with that of the other 3 substances mentioned above. Doses of 5 to 10 mg. per kg. of a neutral salt of tropinone intravenously injected in dogs caused a fleeting hypertensive action in which it resembled *N*-methylgranatoline and pseudopelletierine and differs from tropinol which causes a durable hypertensive action. Accordingly, although the cardiovascular action was not sensibly modified on passing from ketone to alc. function in the 2 compds. with bipiperidine nucleus, it was modified in the 2 compds. with a pyrrolidine-piperidine nucleus. In the latter case the appearance of

the ketonic function suppressed the depressive effects and appeared to increase the properties of the piperidine nucleus.

Mechanism of the preventive action of bismuth against icterohemorrhagic spirochetosis. R. SAZERAC AND H. NAKAMURA. *Compt. rend.* 187, 181-2(1928).—Guinea pigs that were divided into 5 lots and the animals of each lot were inoculated with a culture of *Spirochaeta icterohemorrhagiae* 7, 15, 23, 32 and 45 days, resp., after receiving the Bi compd. The guinea pigs of the first 4 lots lived; those of the 5th lot died showing symptoms of icterohemorrhagic spirochetosis. Accordingly the Bi compd protects the guinea pig between 32 and 45 days. When the Bi compd. and the virus are injected simultaneously, or a previously made mixt. *in vitro* of the Bi compd. and virus culture is injected, the animal is protected for at least 5 months. L. W. RIGGS

Repression of the external secretion of the pancreas during hypoglycemia caused by decamethylenediguanidine. JEAN LABARRE AND PIERRE DESTREE. *Compt. rend. soc. biol.* 99, 337-9(1928); cf. *C. A.* 22, 2790. —In dogs with pancreatic fistulas, or with the "isolated head" technic of J. F. Heymans modified by C. Heymans and Ladon, there was the usual diminution in the glucemia during the 2 to 3 hrs. after the injection of synthalin, accompanied by decrease in the vol. of the pancreatic juice from 4 to 1 or less and somewhat parallel decrease in the lipase, trypsin and diastase activities. L. W. RIGGS

Action of arsenic in simple combination on spirochetes and trypanosomes. R. SAZERAC AND R. VAURS. *Compt. rend. soc. biol.* 99, 372-3(1928).—Elementary As, prepd. by the reduction of H_3AsO_3 by means of NaH_2PO_2 , has a notable activity against *Spirocheta cuniculi* and *Trypanosoma brucei*, but inferior to that of Bi. Pptd. As is not recommended for the treatment of syphilis or trypanosomiasis. L. W. RIGGS

Cardiovascular action of the semicarbazone of pseudopelletierine. JEANNE LÉVY AND RENÉ HAZARD. *Compt. rend. soc. biol.* 99, 382-5(1928).—The combination of semicarbazide with pseudopelletierine reinforces the cardiovascular action of that alkaloid and makes it more const. in its effects. Although pseudopelletierine has feeble adrenaline properties and its depressant action on the myocardium is manifest from the beginning of its action, the corresponding semicarbazone has a more marked adrenaline action, with the cardio-depressor effect later and less marked. Perhaps the latter action is due to a dipiperidic nucleus. L. W. RIGGS

Does chloroform anesthesia modify the excitability of the pneumogastric? B. BEILINE AND A. B. CHAUCHARD. *Compt. rend. soc. biol.* 99, 396-8(1928).—Anesthesia by $CHCl_3$ does not modify the excitability of the cardio-inhibitory fibers of the pneumogastric, or that of the elements innervated by these fibers. L. W. RIGGS

Action of injections of bile salts on the pulse rhythm in the normal monkey. DUMITRESCO-MANTE AND D. HAGIE-CO. *Compt. rend. soc. biol.* 99, 427(1928).—Subcutaneous injection of repeated 0.4 g. doses of Na glycocholate in physiol. saline was followed by a transient lowering of the pulse rate from 226 to 200, followed by an increase in the rate to 270. Na taurocholate in 0.3 g. doses also accelerated the pulse. L. W. RIGGS

Phylactic action of formaldehyde against hemolysis by quinine hydrobromide. P. DODEL. *Compt. rend. soc. biol.* 99, 444-7(1928).—The quantity of HCHO necessary for phylaxia, and not by itself hemolytic, varies according to the presence or absence of blood serum. The optimum concn. of HCHO is about 1.68%, when there is no hemolysis after the addn. of serum and of quinine-HBr. The min. concn. of HCHO to have any restraining action on the hemolysis is about 1.38%. L. W. RIGGS

Action of the neutral sulfate of *o*-hydroxyquinoline on the bacilli of tuberculosis. C. BIDAULT AND ACH. URBAIN. *Compt. rend. soc. biol.* 99, 461-4(1928).—The inhibitive action of the neutral sulfate of quinoline (quinosol or sunoxol) is strong. The virulence of the Koch bacillus disappears completely in 6 weeks in the presence of from 1 to 500 to 1 to 1000 of the drug and is notably diminished in dilns. of 1 to 5000. Injection of guinea pigs with the drug for several weeks did not prevent the development of exptl. tuberculosis. L. W. RIGGS

Curare. L. LAPICQUE AND M. LAPICQUE. *Compt. rend. soc. biol.* 99, 486-8(1928).—Comment is made on the history of several interesting samples of curare, including a sample presented to Paul Bert by Dom Pedro of Brazil. Comparisons of the toxic effects of different curares. MARCELLE LAPICQUE AND CATHERINE VEIL. *Ibid.* 488-90. —Four samples were tested on rats and frogs with varying results for the same sized dose from different samples. L. W. RIGGS

Neutralizing power of soaps on cobra venom. (Venomous cryptotoxin.) MAURICE RENAUD. *Compt. rend. soc. biol.* 99, 496-8(1928).—Cobra venom mixed with soap soln. loses its toxic properties in 4 to 6 days so that a guinea pig may receive without harm an injection corresponding to 40 fatal doses. The neutralization of cobra venom

by soap soln. takes place more slowly than does the neutralization of certain other toxins (cf. Vincent, *C. A.* 20, 3187). Comments with reference to the paper by M. Renaud. NETTER. *Ibid.* 498-9.—The antivenom action of bile, noted by Fraser, and of Na oleorinate, observed by Larson and his collaborators, are cited. The conclusions of these investigators are confirmed by Netter, André, Cesari and Cottoni (cf. *C. A.* 21, 1288). L. W. RIGGS

Comparative study of scopolamine-hydrobromide and hyoscine hydrobromide on the chronaxie of the neuromuscular system of the frog. MARC CHAMBRON. *Compt. rend. soc. biol.* 99, 512-3(1928).—These isomeric alkaloids have an analogous action on the muscle and motor nerves of the frog. L. W. RIGGS

Action of insulin on the development of sarcoma in the rat. A. CADE AND PH. BARRAL. *Compt. rend. soc. biol.* 99, 522-4(1928).—The results of these tests were indeterminate. L. W. RIGGS

Bismuth as a diuretic. H. G. MEIRTENS, P. J. HANZLIK, D. C. MARSHALL AND N. S. BROWN. *J. Am. Med. Assoc.* 91, 223-5(1928).—Expts. with 14 patients, mostly neurosyphilitic, led to the following conclusions: Intramuscular injection of various Bi preps. caused definite and prompt diuresis in man. The action is due to the Bi ion and in doses such as used for the treatment of syphilis the diuresis occurs without known injury to renal functional efficiency. Further tests are necessary to det. the action with reference to diuresis of Bi given by mouth. L. W. RIGGS

Action of saline cathartics. N. B. DREYER. *Proc. Nova Scotian Inst. Sci.* 16, 180-2(1927).—The technic of Babkin (cf. *C. A.* 11, 60) was used. The intestinal movements under the influence of 0.9% NaCl for periods of 5 to 10 min. served as the normal. The introduction of 2.5 to 5.0 cc. of 0.9% NaCl into about 4 in. of the intestine had slight effect, but the introduction of a 1.8 or 2.7% soln. caused a rise in tone with more marked contractions. The amt. of fluid in the intestine increased. If the initial tone was low, isotonic Na_2SO_4 generally caused an increase in both tone and movement, but in no case was water withdrawn from the tissues. With the introduction of hypertonic Na_2SO_4 the segmental and peristaltic movements were marked and in some cases caused a spasm of the intestine. On removing Na_2SO_4 and introducing normal saline the movements diminished sharply. With the introduction of MgSO_4 in isotonic and hypertonic concns. the movements disappeared completely which is remarkable considering the purgative action of MgSO_4 in man. L. W. R.

Alkalies as therapeutic agents in gastric disease. ANNOTATION. *Lancet* 1928, I, 1235-6.—The report by Freezer, Gibson and Matthew in Guy's Hosp. Reports for Apr., 1928, is discussed. $(\text{BiO})_2\text{CO}_3$ was found to be least effective and tribasic Mg phosphate most suitable for the rapid counteraction of gastric acidity. Tribasic Ca phosphates, citrates, and CaCO_3 are almost equally effective. Milk is probably the most important factor in the reduction of acidity, because of its buffer content which enables it to neutralize a considerable quantity of acid. Crohn's idea of the modus operandi of alkali treatment is discussed. F. B. SEIBERT

Tabacin or the toxic principle of tobacco (BARBIERI) 17.

12—FOODS

F. C. BLANCK AND H. A. LEPPER

Harry Snyder (1867-1927). C. H. BAILEY. *J. Assoc. Official Agr. Chem.* 11, No. 3, i-iv(Aug. 15, 1928).—An obituary with portrait. A. PAPINEAU-COUTURE

The chemistry of foodstuffs in 1926 and 1927. A. STRINRUCK. *Chem.-Ztg.* 52, No. 67, Fortschrittsber. No. 3, 69-92(1928). E. H.

Cooking of food products under pressure. J. FROIDEVAUX. Lab. Municipal, Paris. *Ann. fals.* 21, 252-7(1928).—Comparative analysis of boiled meat and vegetables cooked with and without pressure and of the fresh meat used showed that (1) the degree of proteolysis of fresh meat is relatively high; (2) the ratio of amino N to total sol. N is lower in the broth (whether pressure or atm. cooking was used) than in the fresh meat (which is due to the presence of vegetable proteins and gelatin and to superficial coagulation of the proteins of the meat). From a discussion of the results F. concludes that from the standpoint of alimentary value, there is not much to choose between the 2 cooking processes, while from a purely economical standpoint pressure cooking is preferable. A. PAPINEAU-COUTURE

Identification of the prohibited coal-tar colors in foodstuffs. A. R. JAMIESON AND C. M. KEYWORTH. *Analyst* 53, 418-23(1928).—Most schemes for the detection

of artificial coloring matter in foodstuffs do not provide for the detection and identification of picric acid, Victoria yellow, Martius yellow, aurantia and aurine, which are now prohibited by English law. These dyes color wool yellow from an acid bath and do not contain sulfonic groups which tend to make dyestuffs non-toxic and are present in most of the dyes used in coloring foods. Four of the five dyes prohibited are nitro compds. It is desirable, therefore, to det. first, whether the dye present is a sulfonated product. Before attempting to apply any test, ext. the dye by methods given in vol. 5 of Allen's *Commercial Organic Analysis* and conc. the ext. as much as possible. To det. whether the dye is sulfonated or not, heat a little of the ext. with SnCl_2 and HCl until it is partly reduced, neutralize with KOH soln. and look for a brownish red color if a nitro dye is present. Treat the colored soln. with ether and if the color does not go into the ether after shaking, make acid with AcOH , shake and note the effect on the colored layer. With nitro dyes, the color passes into the ether but when the dye is sulfonated, the color is not imparted to the ether either in acid or alk. soln. Pptn. tests were studied with the following reagents: berberine sulfate, AuCl_3 , phosphotungstic acid, silicotungstic acid, AgNO_3 , SnCl_4 and dil. HCl . Characteristic and confirmatory color reactions were obtained with $\text{Ca}(\text{OCl})_2$ soln. and with NaHSO_4 . The following is a summary of the most important tests: *Picric acid*, characteristic rosetts of yellow color were obtained when as little as 5 drops of 0.01% soln. was treated with 1 drop of berberine sulfate. Other alkaloids give cryst. ppts. but they are not as characteristic. KCN gives a brown color on heating and this may be used as a confirmatory test. *Martius yellow*, 5 drops of 0.01% soln., gave characteristic, large yellow needles with 1 drop of berberine sulfate soln. Distinctive crystals were also obtained with 1 drop of AuCl_3 soln. and interesting crystals with 2 drops of AgNO_3 soln. *Aurantia*, 5 drops of 0.01% soln. gave beautiful star-shaped plates when treated with 1 drop of phosphotungstic acid. Characteristic crystals were also obtained with 1 drop of silicotungstic acid. *Victoria yellow*, 5 drops of 0.01% soln., 2 drops of concd. HCl and 1 drop of Wjys soln., boiled a few seconds and then treated with Zn gave a delicate pink color after 12-48 hrs. *Aurine*, since the ext. from the foodstuff is ammoniacal, this dye will be present as the red NH_4 compd. Treat 0.2 cc. of the soln. with 2 drops of chrome-alum soln. and ext. the lake that forms with a little ether. Place a little of the yellow ethereal soln. on a microscope slide; a pink color will appear after the solvent has evapd. The procedure recommended for the identification of the 5 prohibited dyes is as follows: Place about 1.5 cc. of the ext. in each of 5 small test tubes. Use the contents of the first tube for the sulfonation test as described above. Add 1 drop of berberine sulfate to the contents of the second tube and if either picric acid or Martius yellow is shown to be present, try the test with AuCl_3 soln. If there is no ppt. formed with berberine sulfate and no change of color, test the contents of this tube for Victoria yellow by the reduction test mentioned above. To the third tube add a drop of phosphotungstic acid reagent. If a ppt. forms with decoloration, aurantia may be present and this should be confirmed by the silicotungstic acid test. Use the fourth tube to test for aurine and the fifth tube to confirm any of the tests already tried. A table is given of the behavior of these dyes to 14 reagents and photographs of the various cryst. ppts.

W. T. H.

Report of the government laboratory at Amsterdam for 1927. J. STRAUB. *Chem. Werkblad* 25, 161-5(1928).—A brief account of the lines along which original work in connection with the examn. of milk, edible fats, cheese, eggs, flour and bread has been conducted.

B. C. A.

Report on qualitative tests for dairy products; detection of gelatin in milk. SYDNEY H. HALL. State Dept. of Public Health, Boston, Mass. *J. Assoc. Official Agr. Chem.* 11, 299-300(1928).—With fresh, heated and evapd. milk the present official A. O. A. C. test for gelatin gives a very flocculent ppt. on long standing, which ppt. would not be mistaken by a chemist familiar with gelatin picate ppts.; with sour milk, the ppt. appears at once and is sufficiently fine to allow a chance for error. It can be differentiated from true gelatin picate, however, by Seidenberg's modification (*C. A.* 8, 383).

A. PAPINEAU-COUTURE

The milk and dairies order, 1926 (England). D. S. RABAGLIATI. *Munic. Eng. Sanit. Record* 81, 47(1928).—Discussion and preliminary plans for its enforcement in West Riding are given.

C. H. BADGER

Report on milk proteins (determination of casein). H. C. WATERMAN. Office of Expt. Stations, Washington, D. C. *J. Assoc. Official Agr. Chem.* 11, 298-9(1928); cf. *C. A.* 21, 2330.—The method previously described gave filtrates from the casein ppts. which were not clear. Collaborative results obtained were slightly lower than by the present official A. O. A. C. method.

A. PAPINEAU-COUTURE

Report on (the analysis of) malted milk and dried milk. B. G. HARTMANN AND J. T. KEISTER. U. S. Food, Drug and Insecticide Administration, Washington, D. C. *J. Assocn. Official Agr. Chem.* 11, 289-92(1928).—Detn. of H_2O by the water-oven method is not serviceable for malted milk. H_2O is best detd. in malted milk in the same way as in cheese, but drying 1-1.5 g. for 5 hrs., instead of 2-3 g. for 4 hrs.; and the method is applicable also to dried milk. In detg. fat *via* Roesse-Gottlieb, NH_3 should be added with dried milk but should be omitted with malted milk. Though a study of the H_2O -sol. ext. and carbohydrates of malted milk is unnecessary for judging compliance with the established U. S. standard, a study of methods for detg. the various sugars in mixts. of malted milk, sugar and flavoring material is desirable. It has been found that true malted milks and assembled products (mixts. of dried milk and dried malt ext.) can be definitely differentiated by means of the microscope, but the method is not yet ready for publication.

A. PAPINEAU-COUTURE

Methods for the determination of milk solids in mixed feeds. A. B. DAVIS. The Hilton-Davis Co., Cincinnati, Ohio. *J. Assoc. Official Agr. Chem.* 11, 410-7 (1928).—A summary and discussion of methods available for the purpose. A. P.-C.

The Hoyberg method for the determination of fat in milk and cream. B. SPUR. *Z. Fleisch-u. Milchw. 37*, 276-7(1927); *Chimie et industrie* 20, 146-7(1928); cf. *C. A.* 21, 1501.—The advantages of the method as now simplified are: a single soln. is used for milk and cream; the alkyl. of the soln. has been reduced so that it is now harmless; the water bath is heated to only 50°, eliminating danger of burns; its accuracy is quite satisfactory (0.1% for milk, 0.5% for cream). The use of a centrifuge and of a different soln. is recommended for milk contg. less than 0.5% fat and for cheese. Two readings are sufficient, instead of 3 as in the Gerber method. A. P.-C.

A new method for the detection of disease in cows by the determination of the fat content of milk: the Morsin acidless method. K. SCHUTZLER. *Z. Fleisch-u. Milchw. 37*, 277(1927); *Chimie et industrie* 20, 146(1928).—Normal milk gives a rapid and clear sepn. of the fat in the butyrometer. If the milk is doubtful, there is no sepn. or it presents a flocculent turbidity. This peculiarity has been successfully used for the detection of disease in cows.

A. PAPINEAU-COUTURE

The copper content of milk. G. N. QUAM AND A. HELLWIG. Coe College, Cedar Rapids, Iowa. *J. Biol. Chem.* 78, 681-4(1928).—The Cu content of cow, goat and processed milk was detd. The results varied from 0.2 to 0.5 mg. per l. in raw milk to 2.5 mg. per l. in buttermilk.

ARTHUR GROLLMAN

Influence of temperature on rate of corrosion of copper by milk. G. N. QUAM, E. I. SOLOMAN AND ARTHUR HELLWIG. Coe College, Cedar Rapids, Iowa. *Ind. Eng. Chem.* 20, 930-1(1928).—The soly. of Cu in milk increased with rise in temp. to a max. at 85° to 90°. From 90° to 100° the soly. decreased. A time factor of 30 min. was established for these expts. Results are shown by a curve.

J. A. KENNEDY

Simple preparation of yoghurt. S. H. MEIJHUIZEN. *Geeneskund. Tijdschr. Nederland. Indie* 68, 299-300(1928).—The milk of the water buffalo yields an excellent yoghurt after 1 week's standing and may be used for the inoculation of milk. Sheep milk may be used for the same purpose. (Organism not identified.)

M. J.

Report on (the analysis of) ice cream. L. H. McROBERTS. Food and Drug Lab., Bismarck, N. Dak. *J. Assocn. Official Agr. Chem.* 11, 292-8(1928); cf. *C. A.* 21, 3396.—Collaborative comparison of the detn. of ash in ice cream by the official A. O. A. C. method for milk and cream, the official method for sweetened condensed milk, and the previously proposed method (evapn. and ignition of the residue of fat detn. *via* Roesse-Gottlieb) showed that the latter gave results 0.02-0.05% higher than the other 2. This difference is practically negligible when the ash detn. is considered by itself; but it may be of considerable importance if, as McR. suggests, it is used to calc. milk solids not fat (M. S. N. F.). From the published data of Mojonner and Troy, Babcock, Richmond, Van Slyke and Lythgoe, the following av. ratios for normal milk were calcd.: M. S. N. F./ash 12.35, M. S. N. F./protein 2.58, protein/ash 4.79. The M. S. N. F./ash ratio presents the least difficulty because no corrections are needed and the ash figure is doubtless the most const. Whether or not the ash figure could be depended upon in case neutralizers were used would be detd. by calcg. the protein/ash ratio, which would be abnormally low if lime-water or milk of magnesia was used as anti-acid. The Kjeldahl-Gunning-Arnold method was found to be most satisfactory for detg. total N in ice cream. There is need for lactose-sucrose tables based on lactose-sucrose ratios that approximate the compn. of these 2 ingredients of ice cream, *viz.*, 1 lactose to 2.5 sucrose. A method for the bacteriological examn. of ice cream is offered for comment.

A. PAPINEAU-COUTURE

Textures of ice creams as influenced by some constituents. META H. GIVEN.

Evapd. Milk Assoc., Chicago. *Ind. Eng. Chem.* 20, 966-8(1928).—Water in the ice-cream mix freezes into crystals, the size of which det. the fineness or coarseness of the texture of the ice cream. The size of the crystal depends upon the even distribution of numerous tiny air bubbles in the ice cream, which, in turn, depend upon the viscosity of the mix. Mixes contg. gelatin, eggs and dry egg yolk show greater viscosities than the check. Although the variations in the viscosity readings are not great, the differences are much more apparent in handling the mixes. Homogenization and aging increase viscosity. A single homogenized constituent like evapd. milk increases the viscosity and improves texture equal to that of gelatin 0.3, raw egg 2.5 or egg yolk 0.3%. Accompanying photomicrographs illustrate the influence of the various addns. on the texture of the ice cream. Photomicrographs showing the effect of homogenization on fat globules are also shown.

J. A. KENNEDY

Report on (the sampling of) butter, (preparation of the sample for analysis, and analysis of the sample). LLOYD C MITCHELL. U. S. Food, Drug and Insecticide Administration, St. Louis, Mo. *J. Assoc. Official Agr. Chem.* 11, 267-86(1928); cf. *C. A.* 21, 3397; 22, 1415.—Contrary to conclusions reached by other investigators (Ellenberger and Guthrie, *C. A.* 19, 2538; Ellenberger and Newlander, *C. A.* 21, 2511; Smith, Alfend and Mitchell, unpublished report, April, 1926), collaborative results failed to disclose any appreciable loss in H_2O in sampling tub butter by means of a trier, which may be due to differences in the shape and size of the triers used. If the condition of the butter is such that the trier and cores pull dry, 6 cores taken from a tub of sweet butter by means of a trier (in the manner described) will give a representative sample. If the shape of the trier or the condition of the butter is such that the trier and core have drops of water or brine adhering to them, even though practically all the adhering water or brine is transferred to the sample container along with the core of butter, the 6 cores will often give a sample contg. less H_2O than a sample from the mixed entire tub of butter. The variations in salted butter are usually wider than in sweet butter. The results obtained collaboratively showed that no entirely satisfactory method for the prepn. of butter samples for analysis has yet been devised; some careful, experienced analysts obtained remarkably good results by practically any method of prepn., while other analysts equally as careful and experienced failed to get satisfactory results by almost any method. A method of analysis is proposed consisting essentially in weighing 1.0-1.5 g. of sample in a Gooch crucible with a 0.1-g. asbestos pad and contg. about 20 g. of R. R. alundum, 90 mesh, detg. H_2O by drying 2 hrs. at $100-5^\circ$, detg. fat by extg. directly in the crucible with CCl_4 , and detg. NaCl by washing the residue with H_2O and titrating with $AgNO_3$. Collaborative results showed that the proposed method gives lower results for H_2O and higher results for non-fat solids than the official A. O. A. C. method, indicating that drying for 2 hrs. under lab. conditions is probably insufficient. On the whole, the proposed method is considered more rapid and more convenient than the official method. A. P.-C.

Determination of butyric and capronic acids in butter fat. ARTTURI I. VIRTANEN. *Z. anal. Chem.* 74, 321-30(1928).—In the Reichert-Messl. detn. of volatile acids in fats, a distillate is obtained amounting to 110 cc. In the proposed method, this distillate is filtered, 100 cc. of it is redistd. until exactly 50 cc. has come over and this is titrated with NaOH, phenolphthalein being used as indicator. The assumption is made, the justification for which is fully explained, that this distillate contains only butyric, capronic and caprylic acids and that 3.2 cc. of 0.1 N NaOH will always be required by the caprylic acid. The residue in the distg. flask together with the rinsings of the condenser are also titrated with NaOH. It is deduced by a mathematical consideration, and proved experimentally, that 89% of the original butyric acid is recovered in the 50 cc. of distillate and 95% of the capronic acid. From these data it is easy to compute the butyric acid and the capronic acid contents of butter fat. Eight samples of winter butter were analyzed by this method and found to contain 3.12-4.24% of butyric acid and 1.38-2.12% of capronic acid.

W. T. H.

The moisture content of oleomargarine. ROBERT H. KERR. Bur. of Animal Ind. *J. Assoc. Official Agr. Chem.* 11, 382-6(1928).—The H_2O content of 159 samples representing 100 different brands of oleomargarine intended to be used generally as a substitute for butter was generally between 8 and 14%. Examination of 45 samples representing 39 brands of oleomargarine intended to be used in cooking and baking indicated that the H_2O content is generally lower than that of oleomargarine intended for general use as a butter substitute. Examn. of 16 samples representing 15 brands of oleomargarine consisting of vegetable fats churned with skimmed milk showed a H_2O content similar to that observed in oleomargarine consisting in part of the body fats of meat animals and intended for general use as butter substitutes. A. P.-C.

Report on (the analysis of process) cheese. E. O. HURBNER. *J. Assocn. Official Agr. Chem.* 11, 286-9(1928); cf. Williams, *C. A.* 21, 3397.—Adaptation of the official A. O. A. C. method for total tartaric acid to process cheese (in which K bitartrate is used as an emulsifying agent) permits a satisfactory recovery of this constituent within the range used in the manuf. of process cheese. A satisfactory recovery of citric acid from process cheese was obtained by Hartmann and Hillig's modification (*C. A.* 21, 2451) of the Keister-Hartmann method. Since in many cases process cheese is a blend of different types of cheese, with one type predominating, it would be desirable to do further work on the P_2O_5 and CaO contents of these blends with a view to obtaining data for the interpretation of data in connection with detn. of added phosphates.

A. PAPINEAU-COUTURE

Twice-made or pasteurized cheese. L. J. LORD. *Food Manuf.* 3, 419-20(1928).

J. A. KENNEDY

Report on (the analysis of) baking powder. L. H. BAILEY. U. S. Food, Drug and Insecticide Administration, Washington, D. C. *J. Assocn. Official Agr. Chem.* 11, 308-10(1928); cf. *C. A.* 21, 3399.—A mixt. of com. $CaH_4(PO_4)_2$ and com. $Na_2H_2P_2O_7$ was analyzed by detg. CaO and calcg. to $CaH_4(PO_4)_2$, detg. total P_2O_5 , deducting the P_2O_5 equiv. to $CaH_4(PO_4)_2$ found, and calcg. the remainder to $Na_2H_2P_2O_7$. Collaborative results showed only fair agreement. As com. phosphates frequently are mixts. and not single substances, as all the CaO present may not be in the form of $CaH_4(PO_4)_2$, and as phosphates other than $CaH_4(PO_4)_2$ and $Na_2H_2P_2O_7$ may be present, the method would have but very limited application. Addn. of 1-3 drops of caprylic alc. in the gasometric detn. of residual CO_2 was found satisfactory in reducing foam.

A. PAPINEAU-COUTURE

Application to meat and meat food products of a rapid-boiling, short-digestion method for the determination of protein. H. R. MCMILLIN. Bur. of Animal Industry, Washington, D. C. *J. Assocn. Official Agr. Chem.* 11, 408-10(1928); cf. Shedd, *C. A.* 22, 202.—Shedd's method was found to be applicable to meats and meat food products, and it results in saving from 1 to 3.5 hrs. in the analysis of such products as compared with the official A. O. A. C. method.

A. PAPINEAU-COUTURE

Proximate chemical analysis of some Philippine shellfish. SEVERINO B. ETORMA. Univ. of the Philippines, Los Baños. *Philippine Agr.* 17, 125-35(1928).—The av. compn. of 28 varieties of shellfish was, shell 61.8, edible portion 39.91 and total nutrients 20.07%. The edible portion contained moisture 79.89, fat 1.46, protein 9.67, ash 2.82 and undetd. (largely carbohydrate) 6.09%. While the percentages of shell, ash and moisture are relatively the same in both fresh-water and salt-water shrimps, they contain 0.33 and 3.53% fat, 8.26 and 21.18% protein and 11.09 and 0.71% carbohydrates, resp. Analyses of each of the 28 species are presented.

A. L. MEHRING

Studies of tomato quality. II. Effect of soil moisture on the percentage of dry matter in the fruit. R. E. BROOKS AND JOHN H. MACGILLIVRAY. Agr. Expt. Sta., Lafayette, Ind. *J. Assocn. Official Agr. Chem.* 11, 389-93(1928).—The % of dry matter in tomatoes, which greatly affects the cost per unit of food purchased on a wt. or vol. basis, varied inversely with the % of soil moisture, the largest quantity, largest number and largest sized fruit being produced with 70% soil moisture.

A. PAPINEAU-COUTURE

More data on apple by-products and cull utilization. CARL R. FELLERS. Mass. Agr. Coll. and Expt. Sta. *Fruit Products J. and Am. Vinegar Ind.* 7, No. 12, 10-2(1928); cf. *C. A.* 22, 3466.—Addn. information of interest to cider makers is given. There is included material on apple blends, undesirable fermentations in cider apples, cider clarification, pasteurization, sweet cider, vinegar, carbonated cider and cider sirup or boiled cider.

J. A. KENNEDY

Action of prussic acid on fruit and vegetables, and its determination. KARL AMBERGER. *Pharm. Zentralhalle* 69, 481-3(1928).—In the fumigation of premises contg. fruit and vegetables, the latter are known to absorb varying amts. of HCN. Thus, 100 g. of pears contained 9.9, of celery 16.6, of potatoes 7.4 mg. HCN. A. shows that the distn. method (with tartaric acid) and subsequent titration fails to give true values. Some expts. are described which tend to show that the amt. of HCN present in such material may be approx. detd. by developing the Prussian-blue test in an aq. ext. and comparing with it the color developed by a series of controls contg. definite amts. of KCN.

W. O. E

Pineapple storage and export. REES DAVIES. Low Temp. Research Lab., Cape Town. *Farming in South Africa* 3, 883-4, 891(1928).—Temp. is the most important factor in the storage of pineapples, and the best temp. for storage is 45° F. Normal ripening will not take place at lower temps. and higher temps. favor too rapid ripening as well as mold growth. Soft rot, caused by blue molds and yeasts, sets in at 45-50° F.

when the fruit has been bruised. Surface molds do not develop at 45° F. Pineapples produce their own vol. of CO₂ in 5 days at 45° F., and proper ventilation is an important factor in their storage.

Rapid determination of vaseline oil in coffee. MOISA ARMANDA GAUTHIER, K. D. JACOB, Lab. Chim. del Governatorato, Roma *Ann. chim. applicata* **18**, 194-5 (1928); cf. Marotta and Alessandrini, *C. A.* **22**, 2013.—Ext. 2-3 times 25 g. of coffee with a total of 150 cc. of Et₂O, filter, distil, saponify the residue by refluxing for 15-30 min. with 20 cc. of 5% alc. KOH, evap., dissolve the residue in MeOH, agitate with petroleum ether, let sep. 2 liquids, again ext. the MeOH layer with petroleum ether, evap. the petroleum ether layer, dry the residue at 100° for 0.5 hr. and weigh. C. C. DAVIS

Coffee parchment as adulterant of bran and sharps. JOHN EVANS and T. E. WALLIS. *Analyst* **53**, 432-4 (1928).—Some samples of bran have been found contg. about 33% of coffee husks. When the particles of parchment are fairly large, they can be recognized by their pale buff color, resembling old ivory. In sharps the parchment is usually much finer. A few of the suspected pieces should be boiled with chloral hydrate soln. (5:2) and a piece mounted in chloral hydrate for microscopic examn. The amt. of parchment can be calcd. from the crude fiber, coffee parchment yielding about 60% and bran or sharps only 10%. W. T. H.

The manufacture of pickles. CHARLES E. SEARLE. *Food Manuf.* **3**, 415-7 (1928).—Brining as well as pickling is given consideration. J. A. KENNEDY

Investigation to determine a satisfactory standard for beriberi-preventing rices. EDWARD B. VEDDER and R. T. FELICIANO. U. S. Army Med. Dept. Research Board and Bur. of Science, Manila. *Philippine J. Sci.* **35**, 351-90 (1928).—Two hundred samples of rice from different localities were fed to groups of 4 pigeons. The best and simplest method for selecting rice that will prevent beriberi is inspection of the proportion of the external layers remaining. This may be detd. after staining with Gram's iodine soln. No rice having 50% or more of the external layers of the grain produced polyneuritis when fed to pigeons. Human beriberi can be prevented by selecting rice in this manner but it cannot be recommended as a legal standard. The authors propose the following chem. index for beriberi-preventing rice: "Any rice having 1.77% of P₂O₅ plus fat, but not less than 0.4% P₂O₅; or any rice having not less than 0.62% P₂O₅; or any rice having not less than 0.50% P₂O₅ and with at least 75% of the external layers of the grain remaining. No rice of this series possessing these requirements produced polyneuritis in pigeons, and this standard excluded only nine rices out of 200 that afforded protection to pigeons." The indications are that "amino nitrogen is useless as a chemical index, 1.05% ash is a poor index; 0.62% P₂O₅ is somewhat better; and 1.28% fat is the best single chemical index for a beriberi-preventing rice. Of ten rice samples tested, thorough washing reduced the P₂O₅ content from an av. of 0.447 to an av. of 0.197%. Presumably the vitamin content was similarly reduced. In an expt. with twenty insect-infested rices stored for 100 days, an av. total of 2.61% (fat, P₂O₅ and ash) was reduced to 1.71, and seven undermilled rices that should have prevented polyneuritis were converted into highly milled rices that produced polyneuritis." DAVID DAVIDSON

Locust-kernel gum and oil [as a thickener of edible sauces] (WILLIAMS) **29**. Fumigation tests with (CH₂Cl)₂-CCl₄ mixture (HOYT) **15**. Thermophilic and thermophilic microorganisms, with special reference to species isolated from milk (ROBERTSON) **11C**. Apparatus for spray desiccation of milk (U. S. pat. 1,682,596) **1**. Apparatus for treating milk with ultra-violet rays (U. S. pat. 1,681,538) **1**. Apparatus for making coffee or tea (U. S. pat. 17,077) **1**.

Food. ANTONY MAILLOT. Fr. 635,110, May 28, 1927. A nutritive food contains 50-60% diastase, 10% cacao beans, selected and peeled, 20% manioc in semolina and flavored with vanilla.

Deodorizing foods during cooking. THOMAS A. GANNON. U. S. 1,681,531, Aug. 21. A deodorizing packet adapted for use in cooking vegetables or meat by boiling comprises a fabric receptacle impregnated with a water sol. preservative of vegetable colors such as NaHCO₃ and contg. a mass of C of high gas adsorbing capacity.

Apparatus for subjecting food materials to irradiation by ultra-violet rays. FRANCIS C. BEARDSLEE (to R. M. Huffine, J. I. Huffine, and the inventor himself, as trustees). U. S. 1,682,318, Aug. 28.

Yoghurt. ALFRED ZIEHRER. Fr. 634,681, May 19, 1927. See Brit. 272,468 (C. A. **22**, 1814).

Composition for meringues, etc. A. LEO. Brit. 282,923, Oct. 18, 1926. A whipped mass for use in making meringues, marshmallows, etc., is formed of albumin, pectin, sugar and water together with citric acid other acid and a gas-generating substance such as NaHCO_3 .

Dried figs and prunes. THOMAS W. W. FORREST (to Sunland Sales Coöperative Assocn.). U. S. 1,683,068, Sept. 4. Packaged dried fruits such as figs and prunes in which the fruit has become surface sugared through storage conditions are reconditioned by placing the unopened packages of fruit in a receptacle and heating at a maintained temp. somewhat below 100° until the sugar coating has been dissolved and reabsorbed.

Filling containers with preserving, flavoring or condiment liquors. PIERCE CUTLER (to Edward J. Judge). U. S. 1,683,241, Sept. 4. A container is supplied with a concd. soln. of liquid such as sirup and fruit and this is then heated for a "first cook"; a hot "reducing liquid" such as water is then filled in on top of the concd. soln. to adjust the strength as desired, and the container is immediately sealed and subjected to a final cook.

13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

The Society of Chemical Industry and Geigy Plants at Basle. CHARLES E. MULLEN. *Am. Dyestuff Rept.* 17, 547-8(1928).—A description of the plants is given.

L. W. RIGGS

Equipment in the chemical industry and safety of workmen. AM. MATAGRIN. *Rev. chim. ind.* 35, 48-54, 83-9, 138-45, 174-80, 207-12, 240-5, 306-9, 334-9, 370-5 (1926); 36, 7-12, 42-8, 81-5, 114-21, 156-60, 190-3, 226-9, 290-4, 323-8, 357-63, 393-7(1927); 37, 7-12, 47-53(1928).—A review of the app. used in many chem. industries and their safety factor.

P. THOMASSET

Nitration—a unit process of chemical engineering. P. H. GROGGINS. U. S. Bur. of Chemistry, Washington. *Chem. Met. Eng.* 35, 466-7(1928).—Discussion of mixed acid composition for simple nitrations from standpoint of dehydrating value of H_2SO_4 and ratio H_2SO_4 to H_2O at end of nitration.

G. B. TAYLOR

Recovery of vapors of volatile compounds soluble in water. A. FICHOUX. *Chimie et industrie* 20, 21-6(1928).—A mathematical discussion of the recovery of Me_2CO vapors comparing the relative costs of precooling the H_2O and of evapn. of the addnl. amt. of H_2O when the H_2O is not precooled.

A. PAPINEAU-COUTURE

Waste-heat-recovery practice. W. GREGSON. *Power* 68, 251-2(1928); cf. C. A. 22, 3281.—A discussion.

D. B. DILL

Quantitative relations of the counter-current washing process. LUDWIK SILBERSTEIN. Eastman Kodak Co., Rochester, N. Y. *Ind. Eng. Chem.* 20, 899-901(1928).—Formulas and equations are derived whereby the concns. of solute in the liquid adhering to the solid removed from the last tank of a counter-current washing process can be calcd., and these formulas are illustrated for 3-, 4- and 5-tank systems.

W. C. E.

Inhalation, retention and exhalation of dusts and fumes by man. I. Concentrations of 50-450 mg. per cubic meter. P. DRINKER, R. M. THOMSON AND J. L. FINN. *J. Ind. Hygiene* 10, 13-25(1928).—The amts. of dusts and fumes of known compn. retained and expired by man have been detd. as a function of the concn., length of exposure and rate of breathing. Suspensions of ZnO fume (particles 0.15 and 0.4μ) and of marble dust (particles $0.3-6\mu$) were employed. The percentage retentions obtained were 55 ± 9.4 . The concns. inhaled varied from 50 to 450 mg. per cu. m., the exposure from 5 to 45 min., and the rates of breathing from 6 to 18 respirations per min. No appreciable variation of retention with concn. of fume was detected.

B. C. A.

The precipitation of industrial dust. Mechanical and electrical equipment for purifying air. E. LÉVÊQUE. *Bull. soc. encour. ind. nat.* 1928, 529-41(1928).—Mech. methods for removing industrial dust from air include the following: *gravity settling*, in which the air velocity is lowered to permit the dust particles to settle out; *centrifuging*, in which the air is passed through a cyclone separator; bringing the dust-laden air into contact with drops of liquid; *washing the air* by intimate contact with water; *filtering*, in which the air is passed through a suitable filter-medium. *Elec. pptn.* is a very efficient method, and is discussed in a general way at some length.

T. S. CARSWELL

The phosgene accident in Hamburg. BODEWIG. *Z. ges. Schiess-Sprengstoffw.*

23, 287(1928).—Three containers, previously tested at 22 atm., were charged with 10 tons COCl_2 each at 1.5–1.8 atm. After storage for less than 11 mo. the man-head to the windward caused 11 deaths and about 200 cases of illness, some of which were very serious. No excessive pressure was generated in the container, since the shed of corrugated tin, in which the containers were stored, showed no signs of impact. The welded seam showed defects which were ascribed to the expansion of the metal.

Gas as a war weapon from an Italian point of view. (Extracts from "L'Arma Chimica" published by Fratelli Bocca, Turin.) PAGNIELLO. *Z. ges. Schiess-Sprengstoffw.* 23, 101–2, 145–6, 209–11, 244–50, 287–90(1928).—P. describes the chemical warfare munitions of the Italian and Austrian armies, the development of gas protection, the organization of the gas service in Italy, and the importance of chem. weapons.

Contribution to the study of national security. J. VAN HOUT. *Ing. chim.* 16, 77–86(1928).—A study of possible means of chem. warfare.

A mechanical theory of the breakdown of liquid and semisolid insulators. A. GYEMANT. Siemens Schuckert Werke, Berlin. *Naturwissenschaften* 16, 577(1928).—The theory of a recent article (*Wiss. Veroff. Siemens Konz.* 5, 87(1927)) assuming breakdown as a mech. effect due to the elastic gaseous ionized boundary layer electrode-insulator has been worked out quantitatively for d. c. The breakdown value was found to be $F = \sqrt{(10\pi/3)[(\gamma/a) + (2/3)np]}$ where γ is surface tension, a is radius of the gas bubble formed, n a viscosity function and p external pressure. The equation represents the order of magnitude of F , temp., pressure and viscosity influences satisfactorily.

Time lag of insulators. E. J. WADE AND G. S. SMITH. *Elec. World* 92, 309–12(1928); 14 illus.—For very steep wave fronts the spark-over voltage may be 2 or 3 times the lowest value. The time lag varies with the type of insulator and polarity of impulse and approaches the value obtained with a very steep wave front. C. G. F.

ARISI, DANIELE. Distillazione frazionata, teorie, apparecchi di distillazione, rettificazione, colonne a circuito termico chiuso. Apparecchi ad alcool assoluto, costruzione degli apparecchi per la distillazione frazionata. Milano: U. Hoepli. 421 pp. L. 40.

GLUCKSTEIN, S. M.: Chemists and Dividends. London: Inst. of Chemistry of Great Britain and Ireland.

The Sales Engineer: Some Commercial aspects of Metallurgical and Chemical Engineering. London: Mining Publications, Ltd. 112 pp. 10s.

Who's Who in the Chemical and Drug Industries. Edited by Williams Haynes, New York City: Haynes Publications, Inc. 437 pp. \$6.

Liquefying gases. GUSTAV WIETZEL and FRITZ STOEWEENER (to I. G. Farbenind. A.-G.). U. S. 1,682,588, Aug. 28. Gases are cooled and any residual moisture in them is adsorbed in material such as silica gel of high adsorbing power, the gases are liquefied and the adsorbent is regenerated at intervals by means of gases which have undergone the liquefaction operation and are at a pressure not substantially exceeding atm. pressure.

Purifying gases. FRIEDRICH JOST (to Karl Muller). U. S. 1,681,702, Aug. 21. Na hydride or other alkali metal hydride is used for removing small proportions of O , H_2O , CO , CO_2 and sulfurous gases from gases such as may be used in NH_3 synthesis.

Recovering vapors of volatile liquids. H. L. BARTHELEMY (to Ruthaldo Co.). Brit. 282,792, Dec. 28, 1926. In order to facilitate absorption of acetone vapor in water, or similar absorptions, the liquid is distributed in the form of foam in the absorption app. Substances such as AmOH , saponin, egg albumin, or, preferably, NH_4 oleate, K stearate or other soaps, C_6H_6 , toluene, glycerol, etc., may be added and the absorption may be carried out counter-current-wise and continuously.

Refrigerating apparatus of the absorption type. PLATEN-MÜNTERS REFRIGERATING SYSTEM AKTIEBOLAG (to Electroflux, Ltd.). Brit. 282,770–1, Dec. 31 and Dec. 28, 1926.

Refrigerating apparatus of the absorption type. L. SZILARD and A. EINSTEIN. Brit. 282,808, Dec. 29, 1926.

Protecting electric and other cables. JEAN O. GOGRY. U. S. 1,682,076, Aug. 28. An insulated cable is passed through a hot bath of drying oil compn and then subjected

to a drawing action to leave only a thin coating film on its surface; the coated cable is dried and is then passed through a hot bath of a gum resin compn. and is subjected to another drawing operation, and then to a further drawing action and heating to cause the coating materials to combine with each other and to permeate the insulation.

Composition of rubber and paracoumarone resin. STUART P. MILLER (to The Barrett Co.). U. S. 1,682,397, Aug. 28. A compn. which may be used as a *water-proofing or insulating material* is formed by dissolving about 10% of rubber in paracoumarone resin having a m. p. of about 126°.

Heat-insulating material. A. U. WESTFELT. Brit. 283,055, May 28, 1927; Fr. 635,102, May 28, 1927. Waterglass, before being heated to effect increase in vol., is mixed with KClO₃ or other suitable substance which develops gas during the heating. Solid pulverized incombustible material such as a silicate also may be added.

Refractory heat-insulating material. BASIL T. HORSFIELD (to Aluminum Co. of America). U. S. 1,682,675, Aug. 28. A refractory oxide such as Al₂O₃ is melted and strong hollow substantially spherical globules are formed from the molten material; these are used with a refractory binder such as clay to form furnace linings or other refractory articles.

Galvanized steel insulator pins coated with a layer of lead. ARTHUR O. AUSTIN (to Ohio Brass Co.). U. S. 1,682,590, Aug. 28.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Results attained through federal supervision of water supplies used in interstate traffic. A. F. ALLEN. *Texas State J. Med.* 22, 189; *J. Am. Water Works Assoc.* 19, 226(1928).—A historical review commenting on the increasing no. of supplies requiring certification. D. K. FRENCH

Brief summary of bacterial methods and standards in water analysis. H. W. CLARK. *Commonwealth Mass. Dept. Public Health* 14, 3, 78; *J. Am. Water Works Assoc.* 19, 475-6(1928).—Gelatin and 48-hr. incubation have been discontinued and instead agar is used with the count after 4 days' incubation. Litmus lactose for partial confirmation is used in place of endo or eosin methylene blue. It is recommended at present that any member of the coli-aerogenes group and also streptococci be reported as *B. coli*. D. K. FRENCH

Sterilization of water. RYUKICHI JOH. *J. Pub. Health Assoc. Japan* 2, No. 4, 4; *J. Am. Water Works Assoc.* 19, 226(1928).—Chlorination is considered the best method. To prevent odors and turbidity, hypochlorous acid is recommended in place of bleaching powder. D. K. FRENCH

Water works of Bellefonte, Pennsylvania. JAMES D. SIEBERT. *Am. City* 34, 605; *J. Am. Water Works Assoc.* 19, 226(1928).—Descriptive. D. K. FRENCH

New water-filtration plant at Wenatchee, Washington. FRED J. SHARKEY AND S. DEMOSS. *Western Construction News* 2, 50; *J. Am. Water Works Assoc.* 19, 627(1928).—Four 1 m. g. d. rapid sand filter units are provided. Alum is used. The intake with inlets at several levels serves as a sand trap. D. K. FRENCH

Upper San Leandro filtration plant of the East Bay Water Company, Oakland, California. WILFRED F. LANGELEIER. *Western Construction News* 2, 77; *J. Am. Water Works Assoc.* 19, 792(1928).—Water has high turbidity and color at times and Mn is expected. The plant will include nozzle aerators, coagulation units, sedimentation basins, filters, chlorinators and a 3 million gallon storage reservoir. D. K. F.

Residual germicidal action of water treated with ultra-violet rays. C. E. BERNDT. *J. Am. Assocn. Promoting Hygiene and Public Baths* 9, 36; *J. Am. Water Works Assocn* 19, 792-3(1928).—The efficiency of ultra-violet rays properly used is emphasized. D. K. FRENCH

Bacteria in the filtered water in the case of the filtration with the preceding chlorination. T. KOTOKU. *J. Public Health Assoc. Japan* 3, 6, 12; *J. Am. Water Works Assocn.* 19, 626(1928).—Higher bacterial counts were frequently found in filtered chlorinated water than when Cl was not used. The bacteria when isolated were a new type, growing in the sand layer of the filter. D. K. FRENCH

Treatment by chlorination of Lunéville water supply. M. P. VINOT. *Tech. Sanit. Municip.* 23, 128-31(1928).—A description of the installation and management of the chlorinator. C. R. FELLERS

San Fernando chlorination plant, Los Angeles. CARL WILSON. *Western Con-*

struction News 2, 73; J. Am. Water Works Assocn. 19, 628(1928).—Wallace and Tiernan vacuum automatic machines using pilot tubes instead of venturi tubes are employed. The max. flow is estd. at 175 million gallons daily.

Aluminate-alum coagulation of water. C. H. CHRISTMAN *Bull. Chicago Chem. Co. 18A; J. Am. Water Works Assocn. 19, 629(1928)*—A discussion of the advantages and disadvantages of alum and Na aluminat in water purification.

Taste and odor in Sacramento's water supply. RALPH A. STEVENSON, *Western Construction News 2, 76; J. Am. Water Works Assocn. 19, 627(1928)*.—Because of the presence of many algae it was necessary to add Cl, 0.85 to 1.07 p. p. m. before aeration, reducing the regular Cl afterward to 0.25 to 0.15 p. p. m., to effect the proper odor removal.

St. Paul eliminates odors and taste by aeration. R. A. THUMA, *Water Works Eng. 80, 1476; J. Am. Water Works Assocn. 19, 631(1928)*—O content is increased 6% and odors are removed. Water is made more corrosive. The complete cost is about 50¢ per million gallons.

New water-softening plant for Beverly Hills, California. R. L. DARBY, *Western Construction News 2, 31; J. Am. Water Works Assocn. 19, 792(1928)*—The water contains 8 to 10 p. p. m. H_2S . Plant was designed to include aeration, coagulation with lime and alum, sedimentation, secondary alum coagulation and sedimentation and filtration. Cl was probably to be added after secondary coagulation. A detailed description is given.

Great advances in water softening. CHARLES P. HOOVER, *Water Works Eng. 1927, 991; J. Am. Water Works Assocn. 19, 462-3(1928)*—Improvements in handling chemicals, better mixing, Dorr clarifiers, greater efficiency in softening, the proper use of zeolites and the stabilization of softened water by re-carbonating are all considered.

Porter water softener. J. MILLS & CO., *Mech. World 81, 449-50; J. Am. Water Works Assocn. 19, 232(1928)*—A description of a lime, soda ash cold process softener supplying 2500 gallons of softened water per hr.

Enslow chlorine comparator. W. A. TAYLOR, *Can. Eng. 52, 20, 527; J. Am. Water Works Assocn. 19, 471(1928)*.—An illustrated description. The required Cl is affected by org. matter and pH . The residual Cl content required for various conditions is indicated.

Internal corrosion of fuel economizers. E. INGHAM, *Mech. World 82, 467; J. Am. Water Works Assocn. 19, 478(1928)*—As corrosion caused by pure water is usually due to dissolved gases O and CO_2 , it may be avoided if these gases be absent. Much can be done by introducing certain reagents with feed.

Problems in building large water plant. JOHN C. PRITCHARD, *Water Works Eng. 80, 1465; J. Am. Water Works Assocn. 19, 630(1928)*—A detailed description of the new water works plant of the city of St. Louis, Missouri, to be dedicated in 1929. Clarifiers, preliminary coagulation with lime and iron, secondary coagulation with alum and filtration precede pumping to a 100 million-gallon reservoir from which it flows by gravity to the city.

Differential aeration corrosion theory. W. B. LEWIS and G. S. IRVING, *Ing. Boiler House Rev. 40, No. 11, 583-4; J. Am. Water Works Assocn. 19, 231-2(1928)*.—The influence and control of $Ca(NO_3)_2$, $CaCl_2$, $MgCl_2$, $Mg(NO_3)_2$, CO_2 and O are considered.

Preliminary purification of boiler-feed water. J. GUTH, *Bull. assns. franc. des proprietaires appareils vapeur 28, 136-46(1927); J. Am. Water Works Assocn. 19, 230(1928)*.—A discussion of water treatment before it enters the boilers.

Feedwater treatment for high-pressure boilers. V. RÖDT, *Z. Bayerischen Revisionen-Ver. 31, No. 1, 5-6; J. Am. Water Works Assocn. 19, 229(1928)*.—To avoid concns. of sol. salts which cannot be removed chemically, evaporators are recommended.

Purification of water for boiler-feed purposes. T. R. DUGGAN, *J. Eng. Inst. Canada 10, No. 8, 379-85; J. Am. Water Works Assocn. 19, 230(1928)*—A review.

Boiler-feed water. A. G. ELLIOTT, *Pacific Ma. Rev. 25, 20-2; J. Am. Water Works Assocn. 19, 634(1928)*.—Methods of testing for acidity and alk. are given and many analyses are made.

Pretreatment of boiler-feed water. J. GUTH, *Bull. assns. franc. des proprietaires appareils vapeur 8, 299-315; J. Am. Water Works Assocn. 19, 635(1928)*.—A theoretical treatment of physics, chem. purification, and the use of soda and heat.

D. K. FRENCH

Steam at high temperatures. M. STAEGER AND P. BOHNENBLUST. *Metallurgist* (suppl. to *Engineer*) 1928, 15; *J. Am. Water Works Assoc.* 19, 636(1928).—Relates to oxidation of steel by hot water and steam considering the action of dissolved O as well as the direct reaction with the formation of Fe oxide and free H. D. K. F.

Calcium chloride waters, connate and diagenetic. ALFRED C. LANE. *Bull. Am. Assoc. Petr. Geol.* 11, No. 12(1927).—These waters can best be explained as the result of the absorption of water, magnesia and other compds. in the formation of chlorite and the change of volcanic glass to bentonite. The permute water-softening reaction may occur as described by Renick and renders the connate Na:Cl ratio more uncertain. There is little or no sign of the permute regenerating reaction, or of the petrographic products to be expected. There is some indication that the waters in rocks largely composed of volcanic ash are likely to have Ca chloride, and such rocks are likely to have Mg in amts. which can be explained as absorbed from the water. It also appears that there is a similarity in undisturbed connate waters of the same geologic age, but the effect of the circulation from former land surfaces represented by unconformities is pointed out. It is perhaps premature to suggest that in some cases the same shower of volcanic ash may have devastated the sea bottom and killed the animals that yielded the oil, or yielded the silica to the oil-making diatoms and furnished the Cl for the salt water that is found with the oil. C. L. COOPER

Electrometric determination of alkalis of Saki lake water. V. P. IL'INSKII. Gosud. Inst. Prikl. Khimii. *J. Chem. Ind. (Moscow)* 5, 270-4(1928); cf. Sagaidachnuii, *C. A.* 22, 2443.—The knowledge of alkyl. of Saki lake water is important first to biologists for the study of animal and vegetable life of the lake, and second to industrials for extn. of Br from the salt water. The latter is effected by distg. off Br by steam after setting it free by a current of Cl in the course of which part of the Cl is wasted in reacting with alkalis. The alkyl. of the salt water cannot correctly be detd. by titration in presence of usual indicators because its nature is very complicated. When methyl orange is used as indicator the values of alkyl. are higher than with phenolphthalein. On account of the considerable soly. of MgO in MgCl₂ with formation of an unstable compd. $m\text{MgCl}_2 \cdot n\text{MgO}$ which, by diln. with water, reacts with formation of $\text{Mg}(\text{OH})_2$, MgCl_2 , MgCO_3 and CO_2 , the alkyl. of the salt water increases on diln. with double or treble amt. of pure water. The electrometric method (following the prescriptions contained in Müller, *Elektrometrische Massanalyse* (*C. A.* 17, 3307) and Michaelis, *Physical and Colloidal Chemistry* (*C. A.* 20, 611)) has to be used for detn. of the value of alkyl. due to the presence of ions CO_3^{--} , HCO_3^- , NH_3 , NH_4^+ , etc. Curves representing the "potential-alkyl." have been drawn for Saki lake water in various dilns. and the ratios OH/CO_3 , CO_3/HCO_3 , etc., have been detd. Dil. solns. of the salt water contain $\text{Mg}(\text{HCO}_3)_2$. On concg., HCO_3^- disappears where CO_3^{--} increases and, at the same time, combinations such as $m\text{MgO} \cdot n\text{MgCl}_2 \cdot p\text{H}_2\text{O}$ and $m'\text{Mg}(\text{OH})_2 \cdot n'\text{MgCO}_3 \cdot p'\text{H}_2\text{O}$ appear. Org. alkyl. could not be detd. electrometrically but, by decompn. of amines with alkalis and detn. of NH_3 obtained, it is estd. that org. bases are responsible for 2% of the total alkyl. of the salt water. Conclusion: The abs. alkali content of the salt water is a linear function of the concn. of MgCl_2 and is but little affected by the presence of other salts and by the temp. BERNARD NELSON

Determination of hydrogen sulfide in sea water. G. DRUCKER. *Internat. Rev. Hydrobiol. Hydrogr.* 16, 130-3(1928).—The sea water is run directly into 15 cc. of 0.01 N I soln. acidified with 1-2 cc. of concd. HCl. B. C. A.

The national rivers and their functions. C. H. CLAYTON. *Munic. Eng. Sanit. Record* 81, 148(1928).—Sources of "new" water are the under-drainage of agricultural land and rain water running directly into streams off impervious paved surfaces in urban areas. C. recommends that a small coordinating comm. be formed to bring together and analyze the often contradictory governmental literature on rivers.

C. H. BADGER
Volga, the Oka and the Moskova rivers as sources of supply of potable water for the city of Moscow. S. N. STROGANOV AND N. G. ZAKHAROV. *Résumé of Rept. of Communal Service of Moscow 1927* (Russian); *J. Am. Water Works Assoc.* 19, 470-1(1928).—The Volga and Oka are too far away and the Moskova will soon be insufficient. Impounding the last supply seems the most practical solution. D. K. FRENCH

River pollution prevention. J. H. GARNER. *Surveyor* 72, 71; *J. Am. Water Works Assoc.* 19, 625-6(1928).—A general review of the stream pollution situation in Great Britain covering present conditions, proposals for improvement, provision for increased research and the needs and advantages of coöperation. D. K. FRENCH

Specifications and analyses of gravel and filter sand—where sand may be obtained. LEWIS O. BERNHAGEN. *Proc. Ninth Texas Water Works Short School 169, 1927*; *J.*

Am. Water Works Assocn. 19, 793(1928) —The importance of the sand and gravel bed are emphasized and specifications are given.

Determining coagulant dosage by bottle tests. LEWIS I. BIRDSALL. *Proc. Ninth Texas Water Works Short School* 264, Jan., 1927; *J. Am. Water Works Assocn. 19, 793-4 (1928)*.—Tests to be made where waters change quickly in quality are described.

Water of paper mills. NATSUKIHO WATANABE. *J. Public Health Assocn. Japan* 3, No. 7, 1; *J. Am. Water Works Assocn. 19, 471-2(1928)* —Paper-mill wastes comprised straw and lime or paperboard refuse, manila hemp and materials used in the making of Japanese papers. The effect was to increase mosquito breeding, destroy fish and prevent swimming, etc., as well as to generate a variety of gases.

Typhoid fever. E. D. RICH. *Mich. Pub. Health* 15, 79; *J. Am. Water Works Assocn. 19, 228(1928)*.—Improved water supplies have reduced typhoid deaths from 17.4 per 100,000 in 1913 to 2.8 in 1926.

Typhoid and water supply. E. A. WINSLOW. *Mich. Pub. Health* 15, 101; *J. Am. Water Works Assocn. 19, 228(1928)* —The dangers of improperly protected public supplies are emphasized.

Making money out of filter sludge. A. W. BULL. *Water Works Eng.* 80, 1687; *J. Am. Water Works Assocn. 19, 797(1928)* —Because of the slowness of some water-softening reactions it is recommended that sludge from the coagulation basins be introduced into fresh water, thereby making possible a better effluent.

Spent gas liquor in relation to sewage disposal. H. ROSS HOOPER. *Munic. Eng. Sanit. Record* 81, 90-1(1928). The following absorbed O values in p. p. m. (0.0125 N KMnO₄ at 27° for 4 hrs.) are given: spent gas liquor from vertical retorts, 7500, from horizontal retorts, 4000, from strong domestic sewage, 150. Any reduction in the vol. of ammoniacal liquor gives a proportionate reduction in the vol. of spent gas liquor. Some elimination of water may be effected by the use of drier coal, acid scrubbers and better control of steaming in vertical retorts. The water formed during the carbonization process cannot be eliminated. The O-absorbed figure of dil. spent gas liquor (4000 p. p. m.) was reduced about 90% by biological filtration at the rate of 15 gal. per cu. yd. per 8-hr. day and was further reduced to below 20 p. p. m. by a second filtration at the rate of 12 gal. per cu. yd. Equalizing tanks to give an even discharge of the liquor into the sewers is recommended. Lime particles usually present are pptd.

Refuse disposal (Bradford, England). ERNEST CAILL. *Munic. Eng. Sanit. Record* 81, 46(1928).—A saving of £74,000 is made by tipping, as against destruction by fire or furnace. Salvaging is too expensive.

Sanitation in rural areas. G. BELSON CHILVERS. *Munic. Eng. Sanit. Record* 81, 154(1928).—Large capital expenditures cannot be incurred in housing, sewerage, sewage and refuse disposal schemes because of the scattered population. The dilapidated low-ceiled houses and the primitive methods of sanitation make the rural house more unhealthy and unsanitary than the town house. Very few villages have a pure and efficient water supply. They mainly depend on a few scattered wells or occasionally a supply furnished to a few stand-pipes by the lord of the manor. Wind-mills are sometimes used. The sewerage usually consists of earth or pail-closets with frequent difficulty in disposing of the contents. Sewage may be disposed of through broad irrigation or land filtration, and septic tank treatment.

Report of the Hamburg Smoke Abatement Society for 1927. JOHN B. C. KER-SHAW. *Engineer* 146, 111-2(1928) —A review.

Accidents in cyanide fumigation. M. KAISER. *Wiener klin. Wochschr.* 41, 958-60(1928).—Deaths have occurred following fumigation at a low temp. Adsorbed gas was evolved in toxic concns. from mattresses, etc., when warmed to body temp.

Apparatus for diffusion treatment of sewage (U. S. pat. 1,681,890) 1. Apparatus for extracting mucilage from flaxseed for use in steam boiler. (U. S. pat. 1,683,102) 1.

Treating water for preventing corrosive effects. JULIANUS W. M. BOURGOIGNON and CARL L. PHILIPS. U. S. 1,683,521, Sept. 4. See Brit. 271,079 (C. A. 22, 1643).

Device for detecting scale and corrosion in steam-pipe systems. CYRUS W. RICE. U. S. 1,683,489, Sept. 4.

15--SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

Biographical sketches of prominent agricultural chemists and their investigations. III. William Krüger and the Anhalt experiment station at Bernburg. PAUL KRISCHKE. *Ernähr. Pflanze* 24, 17-23(1928).—With portrait and bibliography. L. P. M.

Soil stratometer. Examination of deep-lying soil. M. ZACHLOUL. *Nature* 121, 537(1928).—A simple instrument for measuring variations of the mech. resistance of soil in a vertical direction is described. B. C. A.

The distribution of the important agricultural soils and soil types in France. P. LARUE. *Ernähr. Pflanze* 24, 23-8(1928).—Reproductions of 5 soil maps are given. LAWRENCE P. MILLER

Influence of soil heterogeneity on growth and yield of successive crops. T. EDEN AND E. J. MASKELL. *J. Agr. Sci.* 18, 163-85(1928).—Results of field trials were examd. mathematically with a view of correlating phys. conditions of the soil and plant growth. Ploughing draught, as a measure of phys. condition, showed a fairly close correlation with the germination of wheat, but not with its later development. With swedes no definite relationships were apparent. In both cases the effect of the spacing of the plants on their growth and development was of primary importance. B. C. A.

Study on aqueous soil solutions. Observations on the method proposed by T. Saidel. E. ANGELESCU. *Univ. of Bucarest Bull. soc. chim. Roumania* 10, 14-25 (1928).—A theoretical study of soil sampling. P. THOMASSET

Aqueous vapor pressure of soils. IV. Influence of replaceable bases. MOYER D. THOMAS. Utah Agr. Expt. Sta. *Soil Science* 25, 485-93(1928); cf. C. A. 22, 3251-2.—A group of soils from widely different localities, together with a natural colloidal mineral, were treated to exchange their bases for a single replaceable base, and after the excess of sol. salt had been removed the vapor pressure-moisture relationship was detd. The vapor pressure-moisture curves are greatly influenced by the nature of the replaceable base in the mineral complex. In dry soils the K-treated material has the least and the Ca treated material the greatest water-absorbing power. The Na-satd. material tends to cross the other curves and at high moisture contents has the greatest absorbing power. The existence of hydrates in the Na curve of the colloidal mineral is established and the influence of these hydrates on the slope of the curve is pointed out. It is indicated that the characteristic shape of the Ca curve may also be due to the presence of water of hydration. Most of the soils studied exhibit vapor pressure-moisture relations very similar to the colloidal material of the soils. J. J. SKINNER

A comparison of the available moisture in sod and open soil by the soil-point method. HENRY I. BALDWIN. *Bull. Torrey Bot. Club* 55, 251-5(1928).—Detns. were made with Livingston-Koketsu porous porcelain soil points in an area of abandoned pasture near Grafton, Maine, now undergoing reforestation. Within 24 hrs. after a rain the rate of absorption of water by the points was equal in 2-hr. periods at 5 cm. depth in undisturbed grass sod and in earth from which sod had been removed the preceding year. From 48 to 72 hours after rain the rate of absorption was 4 to 24 times as great in the bare soil as in the sod. In reforestation work, trees should be planted in open pits made by removal of the adjacent sod, as water-supplying power of the soil will thereby be increased. JOSEPH S. CALDWELL

A new method for the determination of the nutrient content of soils by pot investigations. WIESSMANN. *Ernähr. Pflanze* 24, 30(1928).—See C. A. 22, 2425.

LAWRENCE P. MILLER

Replaceable bases and the dispersion of soil in mechanical analyses. MOYER D. THOMAS. Utah Agr. College. *Soil Science* 25, 419-27(1928); cf. C. A. 22, 3252.—A no. of soils from widely sepd. localities, together with a colloidal mineral, all of which had been treated with neutral salts or 0.05 N HCl to exchange their replaceable bases for a single base, were subjected to the mech. analysis process, with and without Na_2CO_3 as a deflocculating agent. In most cases the Na-satd. soil was the most completely dispersed. The addn. of the deflocculating agent to the Na-treated soil either did not increase the dispersion or actually decreased it, except with the calcareous soils, which, when the sol. salt was washed out, had lost by hydrolysis a considerable portion of the Na introduced. In some cases a preliminary treatment with 0.05 N HCl, followed by a removal of the sol. material and subsequent use of Na_2CO_3 as deflocculating agent, gave as complete a dispersion in the mech. analysis as was obtained with the

Na-satn. treatment. Two cases are noted in which the NH_4 -treated material dispersed more completely than did the Na treatment and in one case max. dispersion was obtained with the sample which had been treated with AlCl_3 . The dispersion of the Ca-satd. sample was increased markedly by the addn. of the deflocculating agent, but the reverse was true of the Mg mineral. In view of the exptl. difficulty attending the prepn. of Na-satd. soil it seems likely from these data that the best routine method of dispersing the soil sample for mech. analysis would consist in preliminary treatment with dil. acid followed by the use of Na_2CO_3 as the deflocculating agent.

Studies on the humus-zeolite complex in the soil and on the soil reactions. J. J. SKINNER. ELER SIGMOND. *Matematik. Természettudományi Ertseilo* 43, 51-78 (Hung.), 79-80 (Ger.) (1920).—The most reactive part of the soil is to be found in the humus-zeolite complex, which may be considered as a complex chem. combination in which the anions are the humus- and zeolite-acids, while the cations are the replaceable bases in the soil. In neutral soils the cations are 90-5% bivalent metals such as Ca and Mg. In alkali soils the bivalent cations are partly replaced by univalent metals. In acid soils they are partly replaced by H ions. Tabulated data are given for the total cation equivalent, the distribution of these cations, av. values for neutral soils, typical values for alkali soils, satn. values for several Hungarian and Dutch soils, the relation of the various forms of acidity and the corresponding titration curves.

The use of the Dumas-Dennstedt method in the determination of total nitrogen in soils and agricultural products. E. PARISI. Istituto Superiore Agrario, Bologna. *Ann. chim. applicata* 18, 196-7 (1928).—The Dennstedt method for the detn. of N (cf. *Anleitung zur vereinfachten Elementaranalyse*, 4th ed 1919; Abderhalden, *Handbuch der biologischen Arbeitsmethoden* I, Pt. 3, 501) has been found very satisfactory for soils, flour, etc. The app. and technic are described in detail and illustrated.

The behavior of the nitrogen of molasses distillation residues in soil. E. PARISI. Istituto Superiore Agrario, Bologna. *Ann. chim. applicata* 18, 198-204 (1928).—The high proportion and the nature of the org. substances in residues from the distn. of molasses suggested that when used on soil, there might be denitrification and injury to useful flora. Preliminary expts. showed that in moist soils the distn. residues caused a diminution of total N, and the disappearance of nitric N (cf. C. A. 20, 3207). Systematic tests were therefore carried out (1) to det. the absorptive power of soil for the amino acids present in high proportions in molasses distn. residues; (2) to follow the ammonization and nitrification of these compds; and (3) to verify the loss of N by soils fertilized with distillery residues and maintained at a definite state of humidity. In (1) dried soils were treated with solns of glycocoll, alanine, asparagine, aspartic acid and $(\text{NH}_4)_2\text{SO}_4$ for comparison, and after some hrs the amino acids in the filtrate were detd. In (2) soils treated with CaCO_3 were impregnated with 20% by wt. of water contg. N in the form of leucine, alanine, glutamic acid or betaine, the N being the same wt. in each case. After standing, NH_3 , HNO_2 and HNO_3 were detd. colorimetrically. In (3) the N balance was detd. by the Dumas-Dennstedt method. The same series of expts. in (1), (2) and (3) were then made with molasses distn. residues. The results show that the absorptive power of soil for amino acids (and therefore for 70% of the N of molasses distn. residues) is slight or even negligible. Ammonization of amino acids and of betaine was regular, but very slow and the danger of washing away still existed. Nitrification of $(\text{NH}_4)_2\text{SO}_4$ was very rapid, that of alanine, glutamic acid and leucine was slower and that of betaine was slowest. Losses by liberation of N in gaseous form from wet soils fertilized with molasses distn. residues were practically negligible, and even when large quantities of these residues were used, nearly all their N was transformed into nitrates.

The oxidation of cellulose in the soil. S. WINOGRADSKY. *Compt. rend* 187, 326-30 (1928); cf. C. A. 21, 2042.—Cultures were made on a piece of filter paper spread on silico-gel impregnated with a salt soln. contg. a suitable amt. of N in the form of nitrate. This simple arrangement presented the advantage of following little by little the modifications which take place in the texture of the paper under the influence of the bacteria. Three cases present themselves and are described.

The potash content of soils of East Prussia according to field investigations and the Neubauer method. H. VAGELER. Landwirtschaftskammer f. Ostpr., Königsberg i. Pr. *Ernähr. Pflanze* 24, 220-1 (1928).—Results from the Neubauer method and 1 year's field expts. showed good agreement in 73% of the cases.

Potassium xanthate as a soil fumigant. E. R. DEONG AND JOCELYN TYLER. Univ. of Calif. *Ind. Eng. Chem.* 20, 912-6 (1928).—The rate of decompn. of K xanthate,

as measured by the evolution of CS_2 , is given when combined with HCl and with superphosphate. Lab. measurements have been made of the rate of penetration of CS_2 into both loose and packed sandy and heavy clay soils. The toxicity of xanthate has been tested principally against the root knot nematode. It has been shown that a complete kill is possible in the lab. with the different stages of the nematode, while good control has been obtained in field expts.

J. J. SKINNER

Carbon dioxide nutrition of the forest. D. FRÉHER. *Biochem. Z.* 194, 213-4 (1928).—A correction of a previous paper (cf. C. A. 21, 2042).

H. G.

Fungi in some Colorado soils. E. L. LECLEERG AND FREDERICK B. SMITH. Colorado Agr. College. *Soil Science* 25, 433-41 (1928).—The dominant type of fungi in Colorado soils seems to be species of *Penicillia*, whereas species of *Aspergilli* occur only occasionally. The 3 dominant groups of fungi in order of total numbers and in variety of species are *Penicillia*, *Trichoderma* and *Aspergilli*. The rarer forms are species of *Cephalosporium*, *Verticillium*, *Spicaria*, *Hormodendrum*, *Macrosporium* and *Stachybotrys*. From the 27 soils studied it appears that soils low in moisture apparently favor the growth of *Rhizopus nigricans* and *Trichoderma lignorum*. Moisture did not seem to limit the presence of *Penicillium expansum*. Moisture content, which varied in the samples taken from 1.9 to 5.5%, apparently had no specific effect on the prevalence of other species. The no. of species of fungi isolated was considerably less in soils contg. high qualities of sol. salts than in those of low salt content. Greater numbers of *Penicillia* were found in soils of high salt content than of any other fungus. *Penicillium expansum* and *P. lilacinum* were abundant under these conditions. Species of *Macrosporium* and *Cephalosporium* were also found in soils high in salts. *Trichoderma lignorum* and *Rhizopus nigricans* were abundant only in soils of low content. *Penicillium expansum*, *P. roseum*, *P. lilacinum*, *P. No. 55* and *Fusarium sp.* were found in small numbers under low salt conditions. *Rhizopus nigricans* and *Penicillium expansum* were common to both productive and unproductive soils, but were more abundant in the latter. *Trichoderma lignorum* was present only in the surface of these 2 soils. Greater no. of species of *Fusaria* were isolated from the productive than from the unproductive soils. *Penicillium glaucum*, *P. roseum* and *Cephalosporium sp.* were found only in productive soils, whereas *Macrosporium sp.* was isolated only in the unproductive soils. *Penicillium expansum* was isolated from 5 of the 8 samples of productive soils and also from 6 of the 9 samples of unproductive soils. The no. of species found decreased with depth. Only 2 species were isolated at 42 inches. *Trichoderma lignorum* and *Penicillium expansum* were present at all depths examd. *Aspergillus niger* was abundant only in the surface when present. *Fusarium sp.* was present in both the surface and sub-surface of the soils examd. *Spicaria simplicissima* and *Hormodendrum pallidum* were isolated only from the subsurface. *Penicillium roseum* and *Penicillium No. 50* were found in the surface, whereas *P. duclauxi*, *P. No. 67*, *P. lilacinum* and *P. No. 55* were present only in the subsurface.

J. J. S.

Fifty years of fertilizer practice. PAUL WAGNER. *Ernähr. Pflanze* 24, 244-57 (1928).—An address. Progress has been due largely to improved methods for the scientific study of the role of fertilizers in plants and to better controlled plot expts. In agricultural practice the soil should always be supplied with an excess of K and P, while N should be added as necessary according to the crop grown.

L. P. M.

Eighty-five years of fertilizer investigations in Rothamsted. JOHN RUSSELL. Rothamsted, Eng. *Ernähr. Pflanze* 24, 258-67 (1928).—An address, giving some of the more important results with special reference to potash investigations.

L. P. M.

Investigations by the Neubauer method in connection with long-time one-crop fertilizer experiments in England. TH. ROEMER. *Ernähr. Pflanze* 24, 180-3 (1928).—Soils from expts. at Rothamsted and Woburn when examd. by the Neubauer method for the detn. of available plant nutrients (cf. C. A. 18, 877) gave results which indicate that this method, while not infallible, is nevertheless of great practical value.

LAWRENCE P. MILLER

Time of using nitrogenous fertilizers on winter crops. E. MÖLLER-ARNOLD AND E. FREICHTINGER. *Z. Pflanzenernähr. Düngung* 7B, 119-27 (1928).—On light and medium soils better results were obtained with winter wheat and rye by adding the whole amt. of the N fertilizer in spring than when used part in autumn and part in spring. On stiff clays it was preferable to apply the whole of the N fertilizer in autumn. With rye on sandy soils, the increased yield obtained by a complete nitrogenous dressing in spring as compared with a divided dressing in spring and autumn was mainly in the straw. In this respect the efficiency of a unit of N added in spring was 5 times that of a unit added in autumn when calcd. from a Mitscherlich growth-curve.

B. C. A.

Determination of nitrogen in all its forms in all fertilizers, particularly in mixed fertilizers containing urea and derivatives of cyanamide. THORRL. *Ann. fals.* 21, 257-61 (1928).—The method proposed consists essentially in detg. nitric N (if present), NH_4N (including NH_4 salts, urea, amides, etc.) + org. N ($\text{H}_2\text{O-insol. N}$) and org. N. The following recommendations are made: in destroying nitric N by means of FeCl_3 and HCl do not evap. down to sirupy consistency; in the Kjeldahl or similar digestion, heat as strongly as possible for 2 hrs., by KMnO_4 , CuSO_4 , etc., decoloration not being a sure sign of the complete reduction of the N.

The rate of availability of various forms of sulfur fertilizers. JOSEPH D. HAYNES. Oregon State Agr. College. *Soil Science* 25, 447-52 (1928).—The expts. were made to det. the rapidity of oxidation of S in different soils, the relative value of different forms of S for fertilizers and the effect of S on the chem., phys. and biological changes in the soil. Black gas S becomes available at approx. the same rate as insol. sulfates more rapidly than did the non-inoculated S. Under alk. conditions S yielded to have increased the microflora of the soil probably because of neutralizing the alkali present, which produces a favorable flora for soil organisms. S produces a decided, flocculating effect on alkali soils. Soils treated with 4000 lbs. of S are flocculated rapidly, whereas non-treated soils remain deflocculated. Flocculation starts as neutrality is approached. H-ion concn. changes with amt. of S added to the soil, type of soil and carbonates present. It takes larger quantities of S to change the reaction of alkali soil than of neutral soil.

The biological reduction of mineral phosphates. K. I. RUDAKOV. Bacteriol. Agron. Sta., Moskau. *Centr. Bakt. Parasit. H. Abt.* 70, 202-14 (1927). In a medium consisting of cond. water 1000 cc., mannitol 20 g. and $\text{NH}_4\text{H}_2\text{PO}_4$ which is inoculated with a small quantity of soil, there is a rapid decrease in sol. phosphoric acid under anaerobic conditions. P_2O_5 is reduced to H_2PO_4 , H_3PO_4 and PH_3 by the metabolic activities of soil microorganisms. The addn. of salts of HNO_3 or H_2SO_4 slows the reduction of P_2O_5 because they are more easily reduced and are used up first by the growth of the organisms. Pure cultures of bacilli were isolated which carried out the same processes. Different soils show different degrees of reduction of P_2O_5 , cultivated soil being more active than mountain soil.

Phosphate applications and their influence on chernozem. IV. The reversion of phosphoric acid in soils. M. A. FODOROV. Kharkov Agr. Expt. Sta. *Soil Sci.* 25, 463-72 (1928).—The process of phosphate reversion may be easily demonstrated by the action of CaCO_3 or FeCO_3 on the sol. phosphates of Ca formed in the soil. Water-sol. salts of Ca and Fe bring about the reversion of the phosphates and cause the org. matter to flocculate. It has been shown by dialysis expts. that Ca in soln. prevents the soly. of org. matter. Phosphates of K behave differently from those of Na. They give a less colored ext. A soil treated with normal Na_2PO_4 and washed subsequently with water gives up most of the sol. org. matter formed by this treatment. Further treatment with Na_2PO_4 soln. does not bring more org. matter into soln., 73.2% of the total org. matter from chernozem and 56.6% from forest loam soils have been obtained. A 2% Na_2PO_4 ext. from a soil under cultivation for 12 years gave different amts. of org. matter, indicating the sp. effect of the crops. Solns. of org. matter from different soils may be obtained with Na_2PO_4 exts. The color intensity of a soil ext. with Na phosphate may serve as a test for the detn. of the kind of phosphate used: the secondary salt gives a less intensely colored ext. The Na_2CO_3 and NaHCO_3 may also be distinguished by making a soil ext.

The determination of the phosphoric acid requirement of soils on the basis of the determination of the "relative solubility" of the seedling method and of pot fertilizer experiments. H. BLANCK. *J. Landw.* 75, 343-52 (1928). The relative soly. values show apparently good agreement with the results of the growth expts. if the results of B. are arranged on the basis of the nos. found for the relative soly. and compared with the results of Neubauer's nos. The slight variations from a continuous uniform series in the results of the growth expts. are of course to be referred to the unavoidable sources of error of the growth expts., as these without further discussion are shown by the constantly agreeing plausible variations of the results, and it is thereby shown, that an abs. agreement in general cannot be expected. Nevertheless the variations here are so slight and the variations of the Neubauer nos. so great, that one must concede the advantage, for the case in question, of the method for the relative soly. detn. of P_2O_5 modified by B. over the detn. of root-sol. P_2O_5 by Neubauer, entirely apart from the fact that the value for the relative soly. can be obtained within at least 3 days, while the Neubauer test requires several weeks.

E. F. SNYDER

The calcium carbonate-soil equilibrium and the lime requirement. SANTE MATTSON. N. J. Agr. Expt. Sta. *Soil Science* 25, 429-31(1928).—A period of 7 days was sufficient for the CaCO_3 -soil equil. to be established through a parchment membrane even when the soil material is, at the outset, completely unsatd. The expt. shows that the quantity of Ca adsorbed by the soil material from CaCO_3 is a measure of the degree of satn. and therefore also of the lime requirement. E. F. SNYDER

Contribution to the question of fertilization of hops as an agent against *Pseudoperonospora humuli*. CT. BLATTNY AND FR. DUCHON. Phytopath. Inst. Staatl. Forschungsanst. Pflanzenprod., Prag. *Ernähr. Pflanze* 24, 140-2(1928).—Field observations indicate that good nutritional conditions favor resistance to *P. humuli*. Analyses of strongly infected leaves and weakly infected leaves show that the latter are higher in K and Ca, but lower in N and P. LAWRENCE P. MILLER

Effect of different fertilizers on the amount and quality of tobacco crops. A. V. OTRYGANIEV AND D. V. BALANDA. State Inst. Tobacco Invest., U. S. S. R., *Bull.* 43, 33 pp.(1928); cf. *C. A.* 20, 1127.—The results of field expts. during 1926 and 1927 on tobacco of the Oriental cigaret type show that heavy reddish brown silt loam soil gives a tobacco of continually improving quality and increasing yield as the amt. of P_2O_5 applied to the soil as superphosphate is increased from 22 to 65 kg. per hectare. Thomas meal produces better results than superphosphate, but addn. of lime with the meal lowers the yield. The use of potash and nitrogenous fertilizers alone, or of lime alone, results in no marked increase in the yield. On sandy loam soil the greatest need is phosphatic fertilizer, but the crop is increased also by N and potash, but not by lime; less pronounced improvement in yield follows the use of stable manure. The effects of $(\text{NH}_4)_2\text{SO}_4$ and NaNO_3 are practically identical as regards the magnitude of the crop, but tobacco of better quality is obtained when $(\text{NH}_4)_2\text{SO}_4$ is used. Org. fertilizers, especially green manure (lupin and hairy vetch), improve the quality more than the inorg. fertilizers. Only when lime was applied, either alone or with other fertilizers, was any appreciable change in the soil reaction produced. B. C. A.

The protective effect of potash fertilization against diseases of grains and potatoes. EMIL MÜLLER. Landwirtschaftskammer f. Pommern, Köslin. *Ernähr. Pflanze* 24, 121-3(1928).—Crops grown on plots fertilized only with N and P showed a greater tendency to lodge and were more affected by disease than when grown on plots which had received K in addn. LAWRENCE P. MILLER

Analysis of insecticides. Liquid insecticides miscible with water: alcohol; mercury and formaldehyde; picric acid; nicotine; garlic juice. MAURICE FRANÇOIS AND (MISS) LAURE SÉGUIN. *Ann. fals.* 21, 282-6(1928); cf. *C. A.* 21, 2353; 22, 3255.—General outline of the methods suitable for the qual. and quant. analysis of such insecticides. A. PAPINEAU-COUTURE

Nicotine as an insecticide. G. FOX WILSON. *Am. J. Pharm.* 100, 403-8(1928). W. G. GAESSLER

The removal of spray residue from apples and pears. HENRY HARTMAN, R. H. ROBINSON AND S. M. ZELLER. Ore. Agr. Expt. Sta., *Bull.* 234, 1-38(1928).—Chem. analyses offer the only reliable basis for detg. whether fruit sprayed with arsenicals requires cleaning to meet various Federal and State tolerances. The usual tolerance for As_2O_3 is 0.01 grain per lb. of fruit. In 1927, although approx. 90% of the Ore. crop of pears and apples, i. e., 3,300,000 boxes, contained less than 0.01 grain As_2O_3 per lb., 90% of the crop was subjected to a cleansing process with HCl as the arsenical solvent. As a result of 3000 analyses, a strength of 0.3-1.0% HCl for 1 min. was found most satisfactory, the high concns. being used only in cases of heavy spray residue on the fruit. Mech. means such as brushing or wiping are inefficient. A rinse and spray bath of clean H_2O contg. NaHCO_3 or CaO (concn. not stated) as neutralizers, after the HCl immersion, is very desirable mechanically to remove HCl, As, dirt and mold spores. Wax secretions on fruit in excessive amts. coat the PhHAsO_4 particles and prevent the effective removal of the spray residue by HCl. To overcome this difficulty, the fruit must be harvested at the proper stage of maturity and immediately subjected to the washing process. Oil sprays that remain on the fruit at harvest time likewise protect the spray residue from the solvent action of the HCl and interfere with effective cleaning. Where excessive spray deposits are present, 2 or more washings are necessary. The use of $\text{Ca}(\text{OH})_2$ or Bordeaux mixt. in the spray schedule aids later in facilitating the As removal by HCl. $\text{Al}(\text{SO}_4)_3$, Na_2CO_3 and Celite dust had no effect. By heating the HCl bath to 32-34°, the solvent action on the spray residue was increased to the extent that a 1-min immersion removed even heavy As residues. CCl_4 , C_6H_6 , CCl_3 and gasoline proved unsuccessful as wax solvents in an attempt to expose the As residue to the solvent action of acid. Spreaders and deflocculants in

the spray schedule had no effect on As removal by HCl. Incomplete data indicate that the appearance and keeping quality of apples are enhanced by means of the HCl treatment. Com. CH_3O caused pitting around the lenticels, occasional calyx injury and flesh discoloration in concns. greater than 0.005%. Borax proved to be of little value.

C. R. FELLERS

Further fumigation tests with ethylene dichloride--carbon tetrachloride mixture. L. F. HOYT. Larkin Co., Buffalo, N. Y. *Ind. Eng. Chem.* 20, 931-2(1928); cf. C. A. 22, 2632.—Two and one-half qts. (7 lb.) of 3.1 mixt. of $(\text{CH}_2\text{Cl})_2$ and CCl_4 were used for a 24-hr. period, the temp. being maintained at 75° F. throughout fumigation. The infesting insects were *Tribolium* in flour and Indian meal moth in cereal. The insects were all killed and no reinfestation took place. Baking tests showed no detectable difference in the odor, texture or general appearance. No odor of the fumigant could be detected in the finished product. *Fumigation of moth-infested rugs and furniture* in a 7800-cu. ft. room was done by suspending over steam pipes in the room burlap strips and a runner rug soaked with the fumigant. The door of the room was sealed with paper strips and Na silicate. Results were 100% effective after a 44-hr. exposure.

J. A. KENNEDY

Experiments with Paris green for the destruction of Anopheles larvae. C. J. SCHUURMAN AND A. SCHUURMAN-TEN BOKKEL HUININK. *Geneeskund. Tijdschr. Nederland. Indie* 68, 280-97(1928).—The advantages of Paris green over petroleum are: fishes and useful plants are not damaged. Dusting from above permits a thorough treatment of floating algae. There is, however, the danger of accidental poisoning by wind-carried dust and of As accumulation in the livers of fishes. In the East Indies red earth is the best vehicle, since it is cheap, readily available and non-hygroscopic when dried. Lab. expts. with 1% dusting powders of Paris green with red earth acid clay, MgO and cement as a vehicle gave good results (complete destruction of the larvae within 24 hrs.), except for the cement mixt. *Stoxal* with the same vehicles even in concns. higher than those recommended by Roubaud was by far less effective. The result was equally good in weed-free and weed-covered places. The cost of the Paris green treatment is only 0.3-0.5 of that of the solar oil treatment. M. J.

The dressing of Chinese soil with arsenic. FRANK BROWNE. *Pharm. J.* 120, 320(1928).—J. Cameron (Peking) states that lump As_2O_3 powdered and mixed with the ashes of burnt twigs or grass is much used by Chinese farmers in destroying worms in the soil of gardens where, e. g., cabbage is grown. The mixt. contains about 10% As_2O_3 or less.

S. WALDBOTT

Growing turmeric in the Deccan (DESAI) 11D. Relation of the distribution of certain compositae to the H ion concentration of the soil (TURNER) 11D. Estimation of nitrogen (SIVAN, RAJU) 7. Phosphate and aluminate [for use as fertilizer] (Brit. pat. 283,072) 18.

MANDEVILLE DE REGISMONT, L.: *La fertilisation du sol par la culture et les engrais*. Toulouse: Douladoure freres. 86 pp.

NOLTE, OTTO: *Die Düngung der Grunlandes*. Berlin P. Parcy. 38 pp. Pt. II of Grünland-Bücherei. M. 1.80.

Fertilizers. H. HOLLINGS AND GAS, LIGHT & COKE CO. Brit. 282,327, Oct. 19, 1926. Phosphatic fertilizers contg. NH_3 prep'd. by absorbing NH_3 from coal gas, coke oven gas or the like in ground mineral phosphate mixed with H_3PO_4 , H_2SO_4 , HNO_3 or HCl are treated with air or inert gases such as flue gases to remove loosely combined NH_3 , which otherwise would be lost on exposure of the material. The NH_3 thus liberated may be absorbed in fresh phosphatic material. Various details and modifications of the process are given.

Fertilizers. RHENANIA-KUNHEIM VEREIN CHEMISCHER FABRIKEN A.-G. Brit. 283,194, Jan. 8, 1927. Calcined phosphates such as Thomas slag, Rhenania phosphate or Wolter phosphate are mixed with NH_3 and sufficient acid or acid salt to neutralize the alk. of the phosphate. K salts may be added.

Concrete or masonry fermenting-chamber for nightsoil, etc. J. R. ANGER. Brit. 283,152, Jan. 5, 1927. Structural features.

Insecticide. ÉTABLISSEMENTS JAFEMON. Fr. 634,812, May 21, 1927. Cresyl contg. 15-30% of phenol is emulsified with white soap and glycerol and a little water, and to the mixt. 65-200% by vol. of CS_2 is added. This gives a non-inflammable emulsion of CS_2 for use as an insecticide.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Scientific evolution of the brewing industry. A. FERNBACH. *Bull. assoc. élèves inst. sup. fermentations Gand* 29, 317-25(1928).—An address. A. PAPINEAU-COUTURE

The chemistry of wine making. J. T. HEWITT. H. M. Stationery Office, Sep. 57 pp. —This report deals with all the processes of fermentation of the fresh juices of grapes by means of wine yeast and is based chiefly on the methods used in France and in French North Africa. W. T. H.

Wines of the Gard and Ardèche Departments of 1927 vintage. AUBOUY. *Ann. fals.* 21, 272-81(1928); cf. *C. A.* 21, 2756.—Analyses are tabulated and discussed of 70 wines of the Gard Department and of 33 of the Ardèche Dept. A. P.-C.

Antiseptics used for preserving samples of diseased wines: salicylic acid and sodium benzoate. FONZES-DIAON. *Ann. fals.* 21, 266-72(1928); cf. *C. A.* 21, 296.—A discussion of the effects on the analytical results (particularly volatile acidity) of the addn. of 0.5 g. salicylic acid or 1 g. Na benzoate per l. to samples of wines. Detn. of volatile acidity by the French official method is unaffected by the presence of either preservative, but the method generally gives much too low results. With the other methods, practically the whole of the benzoic acid passes over during the distn., but only a small portion of the salicylic acid, so that the latter only should be used and the use of Na benzoate discontinued. When detg. volatile acidity *via* Blarez a correction of —0.10 g. per l. should be applied for the entrained salicylic acid, and a correction of —0.15 in the Roos-Mestrezat method. The Duclaux method is practically unaffected by the presence of salicylic acid, but it generally gives low results. A. P.-C.

Detection of cider in wine by microscopical examination of the sediment. L. MINDER. *Z. Unters. Lebensm.* 54, 387-8(1927); A. WIDMER AND O. E. KALBERER. *Ibid* 388; cf. *C. A.* 21, 3419.—A question of priority. B. C. A.

Adulteration of brandy and its detection. H. ZEILNER. *Z. Unters. Lebensm.* 54, 389-90(1927).—Statements made by Graff (*C. A.* 22, 1430) are criticized. The fusel oil and ester no. recommended by Graff are deprecated on the ground that the content of higher alcs. in wines and therefore in wine products varies too widely. While analytical nos. are not to be despised, taste and odor are the most reliable indications that wine products so-called are genuine. A reply. G. GRAFF. *Ibid* 391-3.—It is claimed that tasting must occupy a secondary position seeing that it is subjective. Further, the addn. of sugar to wine before fermentation, or of rectified alc. before distn., cannot be detected by taste, but can be detected by detg. the amt. of higher alcs. present, these being in lower proportion in wine products so adulterated. B. C. A.

The pasteurization of beer. DE GRONCKEL. *Bull. assoc. élèves inst. sup. fermentations Gand* 29, 335-41(1928).—Pasteurization of beer cooled and filtered to remove glutins is liable to cause turbidity on keeping, which is shown to be due to the fact that pasteurization disturbs the colloid equil. of beer, reducing the dispersion of the micelles and increasing their tendency to flocculation. This may be counteracted to some extent by regulating the p_H value, keeping it as far away as possible from the isoelec. pt. (p_H 4.2). The use of diastases is also advisable: comparative tests with colupulin, papayotin and pepsin showed that the latter is of no value for the purpose, that 1 g. of papayotin per hl. considerably increases the resistance of the beer to turning turbid but imparts a noticeable taste, and that 3 g. colupulin per hl. is as effective and does not affect the organoleptic characteristics of the beer. Varying the pasteurizing temp. from 60° to 70° and the time from 30 to 60 min. had no effect on the tendency to become turbid.

A. PAPINEAU-COUTURE
The spontaneous heating of barley. J. RAUX. *Brasserie et malterie* 18, 150 5, 166-9(1928).—A discussion of the causes, consequences (to the brewing industry) and prevention of the spontaneous heating of barley. A. PAPINEAU-COUTURE

SCHOELLHORN, FRITZ: *Bibliographie des Brauwesens*. Berlin: Gesellschaft für die Geschichte und Bibliographie des Brauwesens. 436 pp.; M. 8. Reviewed in *Bull. assoc. élèves inst. sup. fermentations Gand* 29, 342(1928); *Brasserie et malterie* 18, 159(1928).

Glycerol. E. A. BARBET. *Brit.* 282,917, Oct. 13, 1926. In producing glycerol by fermentation of sugar, small addns. of SO_2 are used instead of larger quantities of Na_2SO_3 or other reducing agent. Details are given for the fermentation of dild. molasses

Obtaining products from the waste liquor after distilling alcohol from fermented beet molasses. YOSHITARO TAKAYAMA (to Saburosuke Suzuki). U. S. 1,681,379, Aug. 21. The liquor is first dialyzed to remove yeast and uncrystallizable substances, the dialyzed liquor is concd. and treated with an inorg. acid such as HCl or H₂SO₄ to obtain a K salt and betaine salt; and the glutinic acid in the remaining mother liquor is converted into glutamic acid by adding an excess of inorg. acid such as HCl and heating.

Yeast. ERNST IVAR LEVIN. Fr. 625,038, Ma. 1927. See Brit. 271,883 (C. A. 22, 1636).

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

Cortex of Iodina rhombifolia Hook et Ald., Reiss. M. AWSCHALOM. *Rev. facultad cienc. quim. Univ. La Plata* 4, 33-45 (1927). —Analytical data are given, and the method of extn. of the saponins (0.578% of the dry substance) is described.

Lippia hastulata (Griseb.), Hieronymus. E. H. DUCLOUX AND C. ALBIZZATTI. *Rev. facultad cienc. quim. Univ. La Plata* 4, 47-56 (1927). —Analytical data are recorded. The essential n_D^{20} 1.520, $[\alpha]_D^{20} + 53.3^\circ$, f. p. -25.3° , sapon. value 13.95.

B. C. A.

Tabacin, the toxic principle of tobacco. N. A. BARRIERI. *Atti accad. Lincei* [9], 7, 764-8 (1928). —Kentucky tobacco was analyzed by a method which was qualitative and quantitative at the same time and which involved successive extn. with liposolvents (EtOH, Et₂O, CHCl₃, C₆H₆, and petroleum ether) and with hot and cold water. The procedure, which is described in detail, resulted in 9 fractions: (1) a ppt. composed of a mixt. of xanthophyll and a viscous substance which was present in matured leaves, (2) a C₆H₆ fraction, composed of a mixt. of chlorophyll and assocd. substances (cellulose, fats and perhaps waxes); (3) petroleum ether fraction, composed of a mixt. of xanthophyll and other principles; (4) CHCl₃ fraction, composed of a mixt. of the red substance of tobacco and odoriferous principles which can be steam-distd.; (5) aq. fraction, contg. tabacin; (6) insol. salts, chiefly Ca₃(PO₄)₂ and Mg₃(PO₄)₂; (7) a 2nd ppt.; (8) sol. salts, chiefly KCl, K₂SO₄ with traces of K₂HPO₄; and (9) the coloring substance scafatine. After purification, with animal charcoal and by dialysis, tabacin is a lemon-yellow wax-like substance, with odor of NMe₃ and a caustic, irritating taste. It has an acid reaction, is sol. in water and in EtOH in all proportions, is insol. in Et₂O, is hygroscopic, is not attacked by cold lime-water or by prolonged boiling with 1% aq. H₂SO₄. With hot lime water, NH₃ is evolved, and cold 2% aq. KOH decomp. it into tabacol, tabacovnic acid and a sugar. Heated to 110°, tabacin evolves irritating vapors of tabacol, and in smoking cigars and cigarettes considerable tabacol is formed. By the prolonged action of concd. KOH, tabacin liberates NH₃ and forms nicotine. It may therefore be regarded as a *N*-acid glucoside. Tabacin (50 g.), 2% aq. KOH (100 g.), water (500 g.) and a large excess of Et₂O agitated violently for a few seconds, the Et₂O layer sepd. and the Et₂O distd. off, yields tabacol. Exposed to air, it slowly becomes colored. H₂SO₄ added to the alk. layer, the liquid concd., the K₂SO₄ eliminated, leaves a residue of tabacnic acid (which is non-toxic) and a sugar. Tabacol is a lemon-colored, thin liquid, which is basic, is caustic to the touch, has an acrid, penetrating odor, provokes violent sneezing, then coughing and difficult asthmatic breathing. Hot concd. KOH converts tabacol into nicotine, with liberation of NH₃. Nicotine is therefore a decompn. product of the prolonged action of hot KOH, Ca(OH)₂ or Mg(OH)₂ on the residue of the EtOH ext. of tobacco or on dry tobacco. Tabacin, com. nicotine and nicotine from tabacol caused the death of guinea pigs in doses of 9 mg. per 100 g. of animal. The action of tabacol on guinea pigs, is violently convulsant, resembling the combined effects of HCN and strychnine. In doses of 1 mg. per 100 g. of guinea pig, tabacol causes violent contractions, with trismus and difficult breathing and death in 80 seconds by paralysis of the respiratory center. Com. nicotine killed dogs by cardiac and respiratory paralysis when given in doses of 15 mg. per kg. The alc. ppt. (fraction 9) dissolved in water and reprecipd. with EtOH several times yielded pure scafatine, which is yellow, neutral and insol. in all neutral solvents except water. Physiol. analysis by sepn. of the org. and inorg. principles in plant tissues should replace analysis by decompn. with concd. inorg. acids and alkalis now generally used.

C. C. DAVIS

Ungt. hydrargyri albi.—Ungt. hydrargyri flavum. G. WARNECKE. *Apoth. Ztg.* 43, 840-1(1928).—A critical commentary on these 2 HgO salves and their evaluation. W. O. E.

Evaluation of certain official drugs via the German Pharmacopeia. R. DIETZEL AND F. SCHLEMMER. Munich Univ. *Apoth. Ztg.* 43, 907-9, 921-3(1928).—A critical examn. of the official German methods with some suggestions for improvement in the evaluation of KOH, white Hg ppt., Na diethylbarbiturate, Na phenylethylbarbiturate, $\text{Na}_2\text{S}_2\text{O}_3$ and starch solns., MgO_2 , iodometric Fe detn., As_2O_3 , chloramine, unguentum hydrargyri cinereum and Fe prepn. with respect to As. W. O. E.

Spices and aromatics of former German East Africa. KARL BRAUN. *Heil Gewurz-Pflanzen* 11, 55-86(1928).—A descriptive compilation of spices and aromatics in general use by the natives of this erstwhile German colony. W. O. E.

Drug plant culture in Estland. J. STAMM. *Heil Gewurz-Pflanzen* 11, 87-101(1928).—An illustrated article showing the quantities of various plants produced, and the character of cultivation. W. O. E.

Comparative studies of valerian tinctures. WALTER MEYER. *Pharm. Ztg.* 73, 980-1, 993-6(1928).—An examn. of various com. brands purchased on the open market or received directly from the manufcs. revealed such differences in quality that M. felt compelled to prep. his own tinctures for purposes of comparison, using 1 part of the drug to 5 parts of solvent (about 95, 85 and 60% EtOH; spiritus ethereus, both full strength and dil.; Et_2O ; H_2O). The results are given in great detail. W. O. E.

Essential oil of Dacrydium biforme. P. W. AITKEN. *J. Soc. Chem Ind.* 47, 223-4T(1928).—Leaves collected in late autumn, spring and late summer gave on steam distn. quantities of oil varying from 0.21 to 0.42%. The product solidified on cooling to a pasty mass, which on filtration gave a clear oil and a residue of impure diterpene (dacrene) crystals. On immersing the oil in a freezing mixt. crystn. again took place and a further crop of dacrene resulted. The residual straw-yellow oil had n_D^{20} 1.5110, d_4^{20} 0.9360. Among the constituents isolated, after fractionation, were: an oxygenated compd. yielding a hydrochloride, m. 130-1°; a sesquiterpene b.p. 135-45° (hydrochloride, $\text{C}_{15}\text{H}_{25}\text{Cl}$, n_D^{20} 1.507); cadinene and dacrene, $\text{C}_{20}\text{H}_{32}$ (HCl salt, $\text{C}_{20}\text{H}_{32}\text{Cl}$, m. 108.5, $[\alpha]_D^{20}$ 10.9°). On crystn from EtOH, the resulting crystals m. 107°, $[\alpha]_D^{20}$ 48.4°, contg. no Cl and being evidently an isomeride of dacrene, also unsatd. and with the same solubilities, yielding an HCl salt identical with the preceding. This substance is termed *isodacrene*. The *dibromide*, $\text{C}_{20}\text{H}_{32}\text{Br}_2$, m. 139°; the nitrosite and nitrosochloride were viscous liquids that did not crystallize. W. O. E.

Investigation into the germicidal powers and capillary activities of certain essential oils. S. RIDEAL, E. K. RIDEAL AND A. SCIVER. *Perfumery Essent. Oil Record* 19, 285-305(1928).—The Rideal-Walker coeffs. of some 26 pure samples of well-known essential oils have been detd. Quite a no. gave a coeff. many times greater than a no. of com. disinfectants on the market; some of them such as palmarosa (9.0), cinnamon leaf (7.5) and cloves (8.0) may well be styled high-coeff. disinfectants. In a few cases it was found that the germicidal power is roughly proportional to the % of 1 chem. substance in a chosen series of oils; e. g., oil of cloves contains 90% of the phenol, eugenol, and has a coeff. of 8.0; cinnamon leaf contains about 85% eugenol, and has a coeff. 7.5; and bay oil contains about 60% eugenol, and has a coeff. of 5.5. Essential oils dissolved in pure B. P. paraffin lower the interfacial surface tension between such paraffin and water. Since it is well known that the formation of these surface layers, due to adsorption, of disinfectant round an organism is one of the means by which bacteria are killed, attempts were made to det. whether a disinfectant can be evaluated by means of its surface-tension-lowering effect. In a limited series of tests it would appear that this can be done in a general way. W. O. E.

Estimation of camphor in camphor spirit. EUGEN SUSSER. *Pharm. Zentralhalle* 69, 499-500(1928).—The method is based on the ability of camphor to enter into mol. combination with salol, to yield salolcamphor, $\text{C}_{15}\text{H}_{14}\text{O} \cdot \text{C}_{13}\text{H}_{10}\text{O}_2$. Into a 100-cc. weighed Erlenmeyer flask introduce about 10 g. (accurately weighed) camphor spirit and 70 cc. of H_2O . Add exactly 8.0 g. desiccated chemically pure salol, shake the flask, finally allowing the camphor and salol to collect on the bottom of the container. Pass the clear supernatant liquid through a weighed Gooch crucible (the bottom of which carries 2 small filters covered by a porcelain net). Wash the crucible with a few drops of concd. salol spirit. Place the Erlenmeyer flask in a water bath at 60-60°, whereby the entire content of the flask melts to a uniformly oily liquid consisting of salol-camphor and salol. Remove the container from the bath, set aside 1 hr. in a

cool room in order that the salol excess may crystallize. Should this not take place, shake the flask, whereupon rapid crystn. usually results. Transfer the entire content of the flask to the crucible, sepg. the oily salolcamphor from the cryst. salol by suction. Wash the latter by suction with 5 cc. concd. salol spirit (concd. salol spirit dissolves salolcamphor, but not salol). Remove the combined portions of salol to a sheet of smooth paper. Wash the inside of the flask with a few cc. of Et_2O , receiving and evapg. the latter on a watch glass. Press the salol residue on the watch glass between 2 sheets of white paper until no further grease spot forms. Add this salol to the main portion, then dry at first in the air until the odor of camphor is no longer perceptible, then in a desiccator to const. wt. Det. the wt. of flask together with the salol therein then by subtraction the wt. of the salol itself. In the same manner, det. the wt. of the Gooch crucible and the salol contained therein. Addn. of both differences gives the total salol remaining uncombined with the camphor. The camphor content of camphor spirit would then be detd. from the expression: $\% \text{ camphor} = (a/71.06)/b$ in which a = the amt. of camphor combined with salol, b = the amt. of sample taken for analysis, and the value 71.06 = the mol. wt. of salol into that of camphor multiplied by 100. Good results are reported. W. O. E.

Estimation of iodine in thyroid preparations. E. SCHULEK AND A. STASIAK. *Pharm. Zentralhalle* 69, 513-4 (1928); cf. *C. A.* 22, 1437.—The method involves destruction of the org. material by fusion with KOH and subsequent treatment with Br-water or KBrO₃. The completed fusion must be nitrite-free. Should traces of this be present, however, add to the somewhat cooled fusion 3 to 4 cg. grape sugar, and fuse anew for about 2 min. To the cooled and dissolved melt add either 4 cc. Br-water followed by 5 cc. 5% PhOH soln., or better 0.5 cc. freshly prepd. KBrO₃ soln. (1 part 5% NaOH soln. and 1 part satd. Br-water) with PhOH soln. as above. After thoroughly mixing, add 0.1 g. KI, 5 cc. 20% H_3PO_4 , and after 5 min. titrate with 0.01 N $\text{Na}_2\text{S}_2\text{O}_3$ (1 cc. = 0.2153 mg. I), starch being used as indicator. The results obtained by this and the Cl method on 5 different samples are presented in tabulated form. W. O. E.

Evaluation of tragacanth via the D. A.-B. VI. H. ESCHENBRENNER. *Pharm. Ztg.* 73, 966-8 (1928).—A critical discussion of the official Ger. method. W. O. E.

Content of homeopathic iron triturations. H. NEUGEBAUER. *Pharm. Ztg.* 73, 295-6 (1928); cf. *C. A.* 22, 1652.—Reference is made to the analytical findings recently obtained by Simon and Köttschau (cf. *Sudd. Apoth. Ztg.* 67, 786; 68, 65) and the doubt raised thereby as to the accuracy of the method, a series of preps. of the 1st, 2nd, 3d and 4th potencies was examd. and results were obtained which lead to the following conclusion: The 1st to 3rd potencies contain the theoretically expected amt. of Fe, while the 4th potency is slightly high, apparently because of traces of Fe in the milk sugar. W. O. E.

Content of homeopathic iron triturations. A. SIMON AND K. KÖTSCHAU. *Pharm. Ztg.* 73, 865-6 (1928).—A critical reply to the preceding paper indicating that the present authors see no reason to recede from their former position of criticism with respect to the accuracy of homeopathic potentiation. W. O. E.

Content of homeopathic iron triturations. H. NEUGEBAUER. *Pharm. Ztg.* 73, 938 (1928).—Polemical. W. O. E.

Antiphlogistic properties of Australian and East Indian sandalwood oils. FR. BORDECKER AND HEINZ LUDWIG. *Pharm. Ztg.* 73, 738 (1928).—A comparative study of these 2 products with respect to their antiphlogistic influence notably on the rabbit, indicates that the Australian product cannot replace the East Indian oil in therapeutic application. W. O. E.

Control of homeopathic primary products. H. NEUGEBAUER. *Pharm. Ztg.* 73, 920 (1928).—The necessity for the evaluation of primary products used in homeopathic preps. is discussed in connection with certain examples. W. O. E.

Stability of cod-liver oil and phosphorus emulsion. LOFVENICH. *Pharm. Ztg.* 73, 950 (1928).—L. replies to Bohrisch (cf. *C. A.* 22, 3261) and claims that emulsions 3.5 and 11 months old, resp., still showed by the AgNO_3 test the presence of free P although the relative amts. then present are not indicated. Reply. P. BOHRISCH. W. O. E.

Ibid.—B. again emphasizes his previous stand.

Pharmacological assay of digitalis by different methods. J. W. TREVAN, ELLEN BOOCK, J. H. BURN AND J. H. GADDUM. *Quart. J. Pharm.* 1, 6-22 (1928).—The results of assaying 2 samples of digitalis leaf, the one strong and the other weak, in terms of the international standard digitalis powder, with different methods, are described. The agreement obtained between the assay by different methods of the strong sample was fairly good, the discrepancies being not greater than those obtained when different

workers use the same method. There was serious disagreement between the different results for the weak sample, though all methods agreed in showing that the sample was weak. Evidence is given showing that the international standard powder is a practical standard for digitalis leaf and tincture in Great Britain. It is recommended that the prohibition by the Geneva Conference of the use of leaf which differs from the standard by more than 25% be withdrawn, and that having adopted a standard, in terms of which the strength of all leaf should be expressed, the International Conference should be content, as with insulin and pituitary ext., to leave each country to arrange the mechanism of standardization for itself. W. O. E.

New method for the assay of ointments of mercuric oxide and ammoniated mercury. NOEL L. ALLPORT. *Quart. J. Pharm.* 1, 23-7(1928).—*Mercuric oxide ointment.* Into a dry 250-cc. beaker weigh accurately 5 g. of the yellow mercuric ointment (or 1 g. of the red variety), and dissolve directly by warming on the water bath at 50° with 100 cc. of a mixt. of C_6H_6 13, $AcOH$ 2, $EtOH$ (90%) 5 parts. Sat. the resulting clear soln. with H_2S , warm again to 50°, then collect the ppt. on a tared Gooch crucible by means of a suction pump. Rinse the ppt., beaker and tube with hot C_6H_6 and a little alc. Dry at 100° and weigh. The factor for HgO is 0.9309. *Ammoniated mercury ointment.* Into a 250-cc. dry beaker weigh about 2.5 g. of the ointment (or 1.5 g. of the B. P. 1898 prepn.) and dissolve by warming to 70° with 100 cc. of the mixt.: C_6H_6 9, $AcOH$ 10, $EtOH$ (90%) 1 part. Treat the resulting clear soln. exactly as in the preceding method. The factor for ammoniated Hg = 1.0835. W. O. E.

Estrous cycle in the guinea pig and the suitability of the uterus for the estimation of pituitary extract. MARIANNE GOETTSCH. *Quart. J. Pharm.* 1, 34-6(1928).—Diagrammatic representation of the vaginal membrane in the guinea pig is shown in 4 cases. The relation between the wt. of the animal and suitability of the uterus for testing was studied. W. O. E.

Strychnine hydrochloride: its composition and solubility. JOHN EDMUND DRIVER AND STEPHEN PERCY THOMPSON. *Quart. J. Pharm.* 1, 37-43(1928).—The compn. of strychnine-HCl crystals, dried to const. wt. in moist air at ordinary temp., corresponds to the formula $C_{21}H_{22}O_2N_2 \cdot HCl \cdot 1\frac{1}{2}H_2O$. Com. samples of the salt contain rather less H_2O of crystn. than that required by this formula, but more than that required by the formula $C_{21}H_{22}O_2N_2 \cdot HCl \cdot 1.5H_2O$. The soly. of strychnine-HCl in H_2O has been detd. at temps. up to 61°. The soly. at 15.5° recorded in the Pharm. is in need of revision. The soly. of strychnine-HCl is considerably diminished by the presence in the soln. of HCl or metallic chlorides. Detns. have been made of the soly. of the salt in HCl of various concns at 25°. In normal HCl the soly. is only about $\frac{1}{4}$ of the soly. in H_2O . W. O. E.

Solubility and rate of solution of arsenious oxide, B. P. G. E. TREASE. *Quart. J. Pharm.* 1, 44-8(1928).—The rate of soln. of As_2O_3 has been studied under various conditions. In view of the very slow rate at which it dissolves in H_2O , prescribers would be well advised to order solns. rather than the solid, whenever possible. For administration in the solid state, the oxide should be in the finest powder, and more uniformity might be obtained by imposing some limit on the size of the particles. The standard adopted by the U. S. P. appears to be satisfactory. W. O. E.

Progress in tobacco chemistry: obtaining, working up and utilization of tobacco. RICHARD KIESSLING. *Chem.-Ztg.* 52, No. 67, Fortschrittsber. No. 3, 102-4(1928). E. H.

Pharmaceutical manufacturing. F. W. NITARDY. *Am. J. Pharm.* 100, 365-73 (1928).—An address. W. G. GAESSLER

Studies in the genus *Mentha*. XVI. The non-volatile constituents of *Mentha aquatica*, Linne. SAMUEL M. GORDON. *Am. J. Pharm.* 100, 433-49, 509-24(1928).—The material employed for the investigation of the constituents of *Mentha aquatica* L. consisted of the partly dried leaves which had been stripped from the branches. For the purpose of its examn. a quantity (13.8 kg.) of the partly dried and ground material was extd. with alc. The ext. was distd. with steam, yielding 0.85% of volatile oil and an aq. part from which a relatively large amt. of $AcOH$ and a small quantity of trimethylamine was obtained. The essential oil gave a strong reaction for furfural and for certain sesquiterpenes. d_{20}^{25} : 0.8649, n_D^{25} (Abbé) 1.4588, $[\alpha]_D^{25}$ 2.54, acid no. nil, ester no. 39.79, ester no. after acetylation 120.5, ester as linalool acetate 13.93%, alc. as linalool 36.43%, total alc. 47.38, free alc. 36.43. After the distn. of the alc. ext. with steam there was obtained a dark-colored aq. liquid and a quantity of black, oily resin. These products were separately examd. with respect to their constituents. From the above-mentioned dark-colored aq. liquid the following substances were isolated: KNO_3 in considerable amts., formic acid, a small quantity of a yellow pigment

m. 250–253°; glucose (osazone, m. 199–201°); succinic acid; rhamnose (osazone, m. 178°); betaine $C_5H_{11}O_2N$; choline, $C_5H_{13}O_2N$; and a glucosidic material not fully examd. The above-mentioned black, oily resin was extd. with various solvents, whereupon the following substances were obtained: methylamine, NH_4Cl ; linalool; dotriacontane, m. 69.5–70°; a phytosterol, m. 133.5–134°, an oil boiling over a large range and yielding pronounced sterol color tests; lupeol, m. 210°; a mixt. of volatile acids, consisting apparently of butyric, hexylic and heptylic acids, a substance ($C_{10}H_{18}O_2$), m. 212°; a mixt. of unsatd. fatty acids, consisting apparently of linolenic, linolic and oleic acids; an acid $C_{22}H_{40}O_2$ (?), m. 82–3°; melicic acid, m. 86.5°; myristic acid, m. 53°; palmitic acid and possibly stearic acid, "aqualitol," m. 273°; a compd. $C_{26}H_{44}O_2$, m. 261°; a compd. $C_{27}H_{46}O_2$, m. 258°; a compd., m. 319°. W. G. GAESSLER

Chemical characterization of drugs. L. ROSENTHAL *Am. J. Pharm.* 100, 454–62 (1928).—See C. A. 21, 1869. W. G. GAESSLER

A digitalis preparation for intravenous injection. LEWIS C. FREEMAN *Am. J. Pharm.* 100, 463–73 (1928).—F. concludes that the imported European preps. made by this method based upon the biologic tests had a low toxicity by comparison with his samples; that the procedure requires great care in its numerous steps regardless of the time factor which necessitates longer periods than are commonly employed for our U. S. P. preps.; that more extensive work should be done on the entire process to det. whether the active principles can be brought into sol. more effectively, that modifications in $CHCl_3$ extn. might produce more effective yield of total solids; that there is a similarity between this method and the work of Kluft on the HCl and $CHCl_3$ -sol. glucosides but more extensive work should be done to det. the nature of the chem. constituents; that biologic standardizations indicate a difference of soly. and that alc. further exts. sol. active principles; that the product should be standardized not only before pasteurization but also after this sterilization, that the samples are extremely acid and based upon the European prep. this increases on aging, that work with daphnia should be extended with the idea of establishing a new biologic method for the action of digitalis preps. W. G. GAESSLER

Sodium alum. HENRY LEFFMANN AND ILSETH W. STROCK *Am. J. Pharm.* 100, 474–8 (1928).—See C. A. 22, 2522. W. G. GAESSLER

Essential oils as antienzymes. ELLERY H. HARRIS *Am. J. Pharm.* 100, 524–9 (1928).—The antienzyme efficiency of 32 typical essential oils was detd. with the following results, the figures representing % efficiency based on antihydrolyzing powers of the oil in a yeast-sugar soln. at the end of 8 hrs.: estragon 6.8, rosemary 6.8, saffron 8.0, fennel 8.8, turpentine 10.0, lemongrass 10.0, anise 10.8, lemon 10.8, pimento 12.8, orange 12.8, eucalyptus 13.0, mace 13.6, juniper 16.8, rue 18.0, caraway 18.5, sassaparilla 18.5, celery-seed 20.0, camphor 20.0, citronella 20.0, birch 20.5, benzaldehyde 22.0, rose 24.0, clove 25.0, lavender 26.0, oleoresin capsicum 26.8, peppermint 28.0, geranium 28.4, bergamot 29.6, thyme 30.8, pennyroyal 39.0, wintergreen 44.0, cinnamon 48.3. The technic employed was the same as that used in measuring the antienzyme value of various chemicals (C. A. 17, 1106, 1675) and of org. dyes (C. A. 18, 3450). The method used is capable of yielding reasonably concordant results if one adheres to stipulated conditions. $AcOH$ is an efficient antienzyme in concns. above 15% to the absorption of ultra-violet radiations due to the improper storage of oils in glass transparent to short wave lengths not only affects the color but also the antienzyme efficiency. A short bibliography covering the bactericidal action of essential oils is appended. W. G. GAESSLER

Some notes on modern methods of producing cod-liver oil. F. F. HARRIS *Food & Drug* 3, 418 (1928). J. A. KENNEDY

Report on (the analysis of) drugs. ARTHUR E. PAUL, U. S. Food, Drug and Insecticide Administration, Chicago, Ill. *J. Assoc. Official Agr. Chem.* 11, 311–7 (1928); cf. C. A. 21, 3422.—A discussion of the reports of the associate referees on various drugs (see following abstracts). A. PAPINEAU-COUTURE

Report on (the analysis of) arsenicals. (Determination of arsenic in cacodylates. H. WALKS, Drug Control Lab., Washington, D. C. *J. Assoc. Official Agr. Chem.* 11, 326–8 (1928); cf. C. A. 21, 3422; Glycalt, C. A. 20, 3209.—The following method was found to be accurate for the assay of As in Na cacodylate and Fe-As pills: digest the sample (0.2 g. if possible) with 10 g. K_2SO_4 , 0.3 g. starch and 20 cc. concd. H_2SO_4 till colorless, cool, add 20 cc. H_2O , dry the neck of the flask, cool, add 30 g. $NaCl$, 5 g. $FeSO_4$, 1 g. $NaBr$, and 25 cc. concd. HCl and distil as directed in C. A. 20, 3209 for the detn. of As in Fe-As pills. A. PAPINEAU-COUTURE

Report on (the determination of) alcohol in drugs. CHARLES D. HOWARD, State Board of Health, Concord, N. H. *J. Assoc. Official Agr. Chem.* 11, 318–26 (1928);

cf. Lynn, *C. A.* 20, 3209; 21, 3422.—Collaborative results obtained in the detn. of alc. in presence of various interfering substances are given and discussed. The procedure for detn. in presence of I (reduction with Zn dust) is regarded as entirely satisfactory. In the elimination of volatile oils, camphor, CHCl_3 , etc., by salting out and extg. with petroleic ether, 1 washing of the ether ext. with satd. NaCl soln. is insufficient and 3-4 washings should be made; re-extn. of the distillate and subsequent distn. removes the small quantity of oil going over into the 1st distillate, but there is a tendency to lose some alc. In the oxidation of small amts. (about 1%) of CH_2O , it is essential to have an excess of alkali, and completeness of oxidation is readily tested with phloroglucinol or similar reagent. With large amts. (15-30%) of CH_2O , there is possibility of some MeOH being formed by action of alkali on the CH_2O , which would give high results for alc.; the KCN -alkali method for destruction of the CH_2O gave very good results in the hands of one analyst but high results with others. In the destruction of paraldehyde by Tollens' reagent, there appears to be considerable uncertainty concerning what constitutes an "excess" of the reagent. In the colorimetric detn. of small amts. of MeOH (by oxidizing and treating with fuchsin- H_2SO_4 soln.) the intensity of color does not progress in simple proportion to increasing MeOH contents, and the colors obtained should be compared against a series of prepd. standards involving very small intervals rather than measured against a standard by means of a colorimeter. In the detn. of small amts. of EtOH (0.5%) no advantage is gained by making a 2nd distn. to half-vol.; but with materially smaller proportions redistn. to a smaller vol. should preferably be carried out.

A. PAPINEAU-COUTURE

Report on (the determination of) cocaine. ELCAR O. EATON. U. S. Food, Drug and Insecticide Inspection Station, San Francisco. *J. Assoc. Official Agr. Chem.* 11, 328-9(1928); cf. *C. A.* 21, 3422.—Collaborative results obtained by 3 different methods (titration of the alkaloid in a wet way without evapn., hydrolysis to BzOH which is then either weighed or titrated, and an amended method of the Am. Drug Mfrs. Assoc.) showed that accurate results with this easily hydrolyzed alkaloid are rather difficult to obtain, even in the hands of experienced analysts. The principal precautions to be observed are: the solns. of the alkaloid should be worked rapidly; the usual careful quant. precautions should be observed in all stages of the manipulations; the BzOH should be evapd. spontaneously at room temp and draft should be avoided.

A. PAPINEAU-COUTURE

Report on (color tests for) chaulmoogra oil. L. E. WARREN. U. S. Food, Drug and Insecticide Administration, Washington, D. C. *J. Assoc. Official Agr. Chem.* 11, 330-2(1928).—Tests of the Lifschutz color reaction (*C. A.* 16, 987) and of the color reactions of the Jap. Pharm. (4th edit, p. 289) were distinctly disappointing: the colors expected were not sharp, and in some cases those found varied considerably from the standards set. While more or less distinctive for oils of the chaulmoogra group, the tests were of no value in distinguishing the individual oils in the group. The tests were also applied to peanut, cottonseed, rape and castor oils, and while the color reactions of the chaulmoogra group were not duplicated with these common oils, in some cases distinct colors were produced and in a few instances they might be confusing.

A. PAPINEAU-COUTURE

Report on (the analysis of) fluidextract of ginger. J. F. CLEVENGER. Food, Drug and Insecticide Administration, Washington, D. C. *J. Assoc. Official Agr. Chem.* 11, 332-5(1928).—A method is given (technic described in detail) consisting essentially in evapg. the alc., detg. the volatile oil in a Clevenger app. (*C. A.* 22, 2439), detg. the oil (in a Sprengel sp. gr. bottle of about 0.5 cc. capacity) and α (in a 50-mm. micropolarizing tube) of the oil, detg. the Et_2O -sol. solids (in the residue from the volatile-oil distn.), and detg. the I and sapon. values of the Et_2O -sol. solids by modifications of the U. S. P. methods. The end points in the sapon. and I value detns. are somewhat difficult to catch and require some experience. If the volatile matter is not entirely removed from the resin before detg. I and sapon. values, the results obtained will be too high.

A. PAPINEAU-COUTURE

Report on (the analysis of) chloroform and carbon tetrachloride. W. P. KUNKE. U. S. Food, Drug and Insecticide Administration, Washington, D. C. *J. Assoc. Official Agr. Chem.* 11, 335-9(1928); cf. Moraw, *C. A.* 21, 3422.—Weighing CHCl_3 under H_2O was found to be a simple, satisfactory and accurate procedure for detg. the wt. of CHCl_3 drained from a pipet. Devarda's alloy or Al in an alcoholic KOH soln. does not appear to promote a higher yield of chloride, other conditions being the same. The use of the isonitrile reaction (adding PhNH_2 to catalyze the reaction) appears to give a higher yield of chloride than the use of alcoholic KOH alone.

A. PAPINEAU-COUTURE

Report on (the determination of) ipecac alkaloids. A. R. BLISS, JR. Univ. of

Tennessee, Memphis, Tenn. *J. Assoc. Official Agr. Chem.* **11**, 339-41(1928); cf. *C. A.* **21**, 3422.—A collaborative comparison of the Palkin-Watkins hand extn. method, the Palkin-Murray-Watkins automatic extn. method, Palkin-Watkins purification method and U. S. P. X assay showed that: the U. S. P. X assay is unsatisfactory; the automatic extn. method appears more satisfactory, the hand extn. method is more rapid and yields results almost as high as the automatic extn. method, and Et_2O free from peroxides must be used, as peroxides have a notably destructive effect on the ipecac alkaloids.

Report on (the analysis of) mercurials. A. PAPINEAU-COUTURE. Insecticide Administration, Washington, D. C. *J. Assoc. Official Agr. Chem.* **11**, 343-50(1928); cf. *C. A.* **21**, 3423.—Though in general the Bender method gave good results, it is difficult to filter the ppt. without loss, and unless the acidity is carefully controlled the ppt. is not coagulated properly. The iodate method gives high results when applied directly to Hg_2Cl_2 tablets, because in the presence of HCl excipients such as lactose reduce the Hg_2Cl_2 to Hg ; fairly good results were obtained by dissolving and removing the lactose before titrating, but starch and other insol. materials tend to emulsify the mixt., masking the indicator, while if the starch is hydrolyzed by warming the acid mixt., masking is reduced and results are high. In the thiocyanate method there apparently are some oxidation products in soln. which cause some decomposition if allowed to remain in contact with the Hg-Zn thiocyanate ppt., but if the time of contact is limited to 1 hr. satisfactory results are obtained gravimetrically, but not volumetrically. Very satisfactory results were obtained by the I method, provided the lactose and other H₂O-sol. excipients were previously removed.

Report on radioactivity in drugs and water. J. W. SALE. U. S. Food, Drug and Insecticide Administration, Washington, D. C. *J. Assoc. Official Agr. Chem.* **11**, 342 (1928).—A series of synthetic solid, semi-solid and liquid samples contg. known quantities of Ra were prepd. and will be submitted to collaborative study according to previously published methods (*Sale, C. A.* **19**, 3145, **21**, 3422).

Report on the determination of pyramdone. FRID L. ELLIOTT. Food, Drug and Insecticide Administration, Baltimore, Md. *J. Assoc. Official Agr. Chem.* **11**, 350-2(1928); cf. *Rabak, C. A.* **21**, 3423.—Collaborative results showed that pyramdone can readily be extd. by means of CHCl_3 from either a dil. alkali or an ammoniacal soln. Irregularities in the results obtained by the hydrochloride method appear to be due chiefly to difficulty in drying or complete removal of free HCl, but the method is of some value as a check on extd. residues. The dried residues have a slight tendency to increase in wt., especially in the case of pyramdone-HCl, and they should be weighed as quickly as possible.

Report on microchemical methods for alkaloids. C. K. GLYCART. U. S. Food, Drug and Insecticide Administration, Chicago, Ill. *J. Assoc. Official Agr. Chem.* **11**, 353-5(1928); cf. *C. A.* **21**, 3423.—Further collaborative work confirmed the reliability of microchem. tests for the identification of morphine, codeine, cocaine and strychnine. Satisfactory results were also obtained with pilocarpine. The crystals formed by atropine with Wagner's reagent were not found to be sufficiently characteristic.

Report on (the analysis of) silver proteinates. LEWELYN JONES. U. S. Food, Drug and Insecticide Administration, Chicago, Ill. *J. Assoc. Official Agr. Chem.* **11**, 355-6(1928); cf. *C. A.* **21**, 3423.—The dialysis method proposed by Eaton (*C. A.* **20**, 3145) for detg. the acidity or alkali. of Ag proteinates gives satisfactory results and is of value. Special precaution should be observed in the choice of parchment paper. Potentiometric titration (with quinhydrone electrode) gave curves exhibiting no definite break, so that it was practically impossible to det. the neutral point by this method.

Report on (the determination of) terpinol hydrate (in terpinol hydrate elixir). C. W. HARRISON. U. S. Food, Drug and Insecticide Administration, Minneapolis, Minn. *J. Assoc. Official Agr. Chem.* **11**, 358-60(1928).—Collaborative results obtained via Murray (*C. A.* **21**, 2357) were about 2% too high. The method really detcs. CHCl_3 ext., and is not applicable to the detn. of terpinol hydrate in mixts. contg. other CHCl_3 -sol. extractives which might be removed by alc.- CHCl_3 under these conditions and not removed by the NaCl-soln. washing or spontaneous evapn.

Report on the bioassay of drugs. J. C. MUNCH. U. S. Food, Drug and Insecticide Administration, Washington, D. C. *J. Assoc. Official Agr. Chem.* **11**, 362-77(1928); cf. *Schwartz, C. A.* **21**, 3423.—Collaborative work on the cat-eye method previously described showed it to be satisfactory for *myotic* as well as for *mydriatic*. Extensive collaborative tests on the assay of tincture of *digitalis* showed that when the U. S. P.

X 1-hr. frog method is followed in detail by a careful and experienced analyst, the probable error of results obtained is $\pm 10\%$.

A. PAPINEAU-COUTURE

Determination of alcoholic extractive in gum benzoin. T. N. BENNETT AND C. F. BICKFORD. U. S. Food, Drug and Insecticide Administration, New York. *J. Assoc. Official Agr. Chem.* 11, 386-8(1928).—From a comparison of various methods of detg. alc. ext. in gum benzoin, B. and B. conclude that the U. S. P. X method is long and tedious and yields results in error, since several substances which might be considered as active ingredients of gum benzoin are lost during the course of the detn. Methods depending on the detn. of the alc. ext. are considered best and most accurate, and the technic considered to be easiest consists essentially in extg. the gum in a continuous extractor for 5 hrs. with 0.5% NaOH soln. in 95% alc., weighing the residue in the thimble, and separately detg. H_2O by xylene distn.

A. PAPINEAU-COUTURE

The yeast method for silver proteins. H. WALES. Drug Control Lab., Food, Drug and Insecticide Administration, Washington, D. C. *J. Assoc. Official Agr. Chem.* 11, 396-8(1928).—In using Pilcher and Sollmann's yeast method (*C. A.* 17, 2032) for detg. the strength of Ag proteins, consistent results could not be obtained with $AgNO_3$ solns., but no difficulty was encountered in obtaining checks for the inhibitory concns. of the Ag proteins. In its action on yeast, $AgNO_3$ seems to differ entirely from the Ag proteins; W. believes that the inhibitory action of Ag proteins on the growth of yeast is not due to the Ag^+ concn., and the results of potentiometric titrations (to be published) strengthen this belief.

A. PAPINEAU-COUTURE

Assay of trional tablets. L. E. WARREN. U. S. Food, Drug and Insecticide Administration, Washington, D. C. *J. Assoc. Official Agr. Chem.* 11, 404-7(1928).—It was found that a temp. above 50° cannot be employed without loss in drying trional residues after the solvent has been removed by evapn., but that dry trional residues do not lose wt. when kept over H_2SO_4 in a partial vacuum. Collaborative results obtained on samples of known compn. by extg. with $CHCl_3$, evapg. in a current of air at atm. temp., and drying to const. wt. over H_2SO_4 were slightly high (av. about 101.5% of theory).

A. PAPINEAU-COUTURE

Neroli. WALTER TREFF. *Parfumerie moderne* 21, 169, 171(1928); cf. *C. A.* 22, 3262.—A detailed description of the results of analysis of 7 samples of corn neroli including d_4^{20} , n_D^{20} , acid no., Ac no., and sepu. and examn. of the primary alcs. by means of the phthalic ester. Three of the samples consisted of practically pure neroli; 3 others contained citronellol; and the 7th probably contained an unidentified terpene alc., $C_{10}H_{18}O$.

A. PAPINEAU-COUTURE

The synthesis of derivatives of glycolic acid with a cocaine-like action. FRIGYES KONEK AND LAJOS STRAUB. *Matematik. Természettudományi Értesítő* 41, 14-8 (Hung.), 19 (1925). (In German).—According to the general reaction $C_6H_5COONa + BrCH_2COOEt \rightarrow NaBr + C_6H_5COOCH_2COOEt$, K. has prepared the Et and Me esters of *o*-, *m*-, and *p*-nitrobenzoylglycolic acid and of *o*- and *p*-nitrocinnamyl glycolic acid. The catalytic reduction of these nitro compds. gave the corresponding amino compds. The Me and Et esters of *p*-aminobenzoylglycolic acid has a local anaesthetic action similar to cocaine. The hydrochlorides partly dissociate in aqueous soln. and must therefore be used with other solvents.

J. S. REICHERT

Preservation of isohemagglutinating serum with phenolized glycerol. MARCUS W. LYON. *Proc. Indiana Acad. Sci.* 37, 297-8(1927).—Two ampoules, one of parasthenic serum and one of antiparasthenic serum, which had been in the ice box for 4 years were tested against freshly prepd. parasthenic and antiparasthenic serums, with the cells of 50 different persons distributed among the 4 human blood groups. The tests with the old and the new serums gave identical agglutinations. Consequently isohemagglutinating serums may be preserved with 5% of a 10% soln. of phenol in glycerol for at least 4 years.

L. W. RIGGS

Chlorinated carron oil for burns. J. W. TOMB. *Med. Press* 1928, 90; *Pharm. J.* 120, 129(1928).—Linimentum calcei made with soln. of $CaOCl_2$ is sufficiently antiseptic to prevent suppuration of extensive burns, and is non-poisonous if absorbed. To prep. a liniment contg. 0.05 - 0.1% of Cl, this strength giving the best results in healing burns of the 2nd or 3rd degrees, add 1 part of Liq. Calcei Chlorinat., Brit. Pharm. to 15-20 parts of lime water. The liniment made from this soln. and linseed oil remains strongly antiseptic for an indefinite period.

S. WALDBOTT

Sirup of tolu. J. F. LIVERSEGE. *Pharm. J.* 120, 93, 141; *Chemist and Druggist* 108, 64(1928).—In the prepn. of sirup of tolu, the Brit. Pharm. 1914 directs dissolving 660 g. of sugar in 400 cc. of hot aq. soln. of balsam tolu, the total to weigh 1000 g., implying a loss of 60 g. by evapn. This prepn. should have a sugar content of 66% , if no evapn. took place, the sugar content is 62% . To prep. *sirupus toluianus*, the

Brit. Pharm. Codex directs mixing the aq. soln. of tolu with Brit. Pharm. Sirup (sugar 66%) in the ratio of 1:7. As this diln. reduces the sugar content to 58.3%, the product is not identical with the Brit. Pharm. prepn. In 6 com. samples, the % of sugar varied from 58.3 to 61.6; another contg. 54.7% was condemned.

Bitter blaar (*Brachylaena elliptica*); preliminary note. E. C. BENNISON. *Pharm. J.* 120, 318 9(1928).—This plant (also called *bitter leaf*), a shrub growing in the sand dunes of S. Africa and in Natal at sea level and up to 5000 feet, is said to yield a remedy for diabetes; a decoction of the leaves has been used as a gargle in sore throat. From a sample package the botanical diagnostic characters of the leaves were detd. and not a glucoside. Digestion with H₂O yielded mucilage, tannin and a bitter principle after evapn., addn. of very dil. H₂SO₄ and filtering off a flocculent ppt. gave indications of alkaloids with Thresh's and Mayer's reagents. Extn. with 60% alc. gave similar results. By evapg. A, addn. of very dil. H₂SO₄, CHCl₃, and NH₃ in faint excess, a cryst. substance was obtained upon evapg. the CHCl₃ soln.

Early pharmacy in Bohemia. J. G. F. DRECK. *Pharm. J.* 120, 319 26(1928). Historical notes on Bohemian pharmacy since the founding of Prague University, 1348, and a record of *Czech herbs* of the 16th century.

Apparatus for obtaining mixtures of gases, particularly for anesthesia. Fr. pat. 635,002 1.

Dias Cavaroni, Joseph. Contribution à l'étude de l'efficacité réelle du nitrate de soude, de la trinitrite, du gui et de l'hydrate de chloral comme médicaments hypertenseurs. Montpellier: Firmin et Montane, 107 pp.

Medicinal capsule. JOSEPH A. HORGAN. U. S. 1,683,166, Sept. 4. Capsules adapted for intestinal administration of medicines are formed of material treated with an alc. soln. of benzoin or a similar prepn.

Cod-liver oil preparations. K. KAWAI. Brit. 283,267, Oct. 5, 1926. A concentrate rich in vitamin A is prepd. by saponf. 50-75% of the saponifiable portion of ordinary cod-liver oil and then sepg. the unsaponf. oil, contg. vitamin A and other effective ingredients, from the saponf. material, e. g., by stratification and centrifuging or by use of milk of lime to form an insol. soap which is then sepd.

Amino- and diamino-acridines. CHEMISCHE FABRIK VORM SANDOZ. Brit. 283,184, Jan. 6, 1927. Amino- and diamino-acridines and their alkoxy derivs. or halogen alkylates are converted into salts with bile acids by interaction of the base and acid in a solvent or by reaction between salts of the base and acid. The products possess antiparasitic properties.

Auromercaptocarboxylic acids and salts. WALTER SCHOELLER and HANS G. ALLARDT. U. S. 1,683,104, Sept. 4. An aliphatic mercaptocarboxylic acid is treated with an auri salt such as K auribromide, in the presence of SO₂. α-Auromercaptopropionic acid forms a Na salt which is a yellowish amorphous powder, readily sol. in water and insol. in org. solvents. The Na salt of β-auromercapto-α-amunopropionic acid forms a white powder of similar solv. These compds. may be used as therapeutic agents.

1-Auro thioglucose and similar compounds. WALTER SCHOELLER and HANS G. ALLARDT. U. S. 1,683,105, Sept. 4. 1-Auro thioglucose is made by dissolving thioglucose in water, adding the mol. proportion of SO₂ in aq. soln., adding a soln. of K auribromide, and pptg. with alc. Instead of thioglucose as starting material there may be used, for producing similar products, mercapto sugars or other compds. contg. sulfhydryl groups and also a plurality of OH groups. 1-Bismuth thioglucose is also described; also 1-cadmium thioglucose. These compds. may be used for pharmaceutical purposes.

Barbituric acid derivatives containing at least one alkynyl group in the 5-position. MAX BOCKMÜHL, RUDOLF SCHWANE and GUSTAV EHRHART (to Winthrop Chemical Co.). U. S. 1,682,062, Aug. 28. Compds. of soporific properties are obtained by the whole or partly replacing, in the usual alkylation methods for prepg. soporifics, the esters of the satd. aces. by esters of the alkinols. By starting from monoalkyl-esters, malonic esters, alkylalkynylmalonic esters are obtained which can be converted by the means of urea and alkylates into the corresponding barbituric acid compds. The same substances can be obtained by causing the esters of the alkinols to act upon the monoalkylbarbituric acid salts. Compds. also may be prepd. contg. both an alkenyl

and an alkynyl group, such as allylpropargylbarbituric acid. Examples are given of the production of isopropylpropargylbarbituric acid, m. 165°, isopropenylpropargylisopropylbarbituric acid, m. 157°, propargyldiethylmethinebarbituric acid, m. 175-8°, and isopropenylpropargylbromide, m. 65-7° (which may be used as an intermediate in the production of isopropenylpropargylisopropylbarbituric acid). The barbituric acid derivs. mentioned are stated to be suitable for use as therapeutics without any bad after-effects.

Immunizing serums and vaccines. W. WEICHLEIN. Brit. 282,780, Dec. 24, 1926. Inoculating material for direct immunization or for use in the production of serums is prepd. by treating bacteria or their products or virus with weak solns. of aniline dyes such as methylene blue, brilliant green or fuchsine and keeping the mixt. at blood temp. for 1-2 days. Among the organisms which may be treated are those of murrain, fowl cholera, swine plague, foot and mouth disease, gapes, paratyphoid and smallpox.

Depilatory paste containing barium sulfate and barium sulfide. CARL S. MINER and ELMER W. TROLANDER (to Delatone Co.). U. S. 1,682,181, Aug. 28. A mixt. suitable for use on the skin comprises BaSO₄ 80, Ba sulfide 8 and water 116 parts.

Hair lotion. MARLETA M. McDANELD (one-half to Esie M. Hereford). U. S. 1,682,230, Aug. 20. A "permanent wave" lotion comprises borax 3.75, NaHCO₃ 3.5, starch 0.4, linseed oil 0.17 and water about 94 parts.

Treating the hair with keratin. JAMES C. BROWN (to E. Frederics, Inc.). U. S. 1,681,170, Aug. 21. Keratin is deposited on the hair, e. g., from an ammoniacal soln. of keratin, while applying heat to the hair (suitably at a temp. of about 100°) to produce a "permanent wave."

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

Manufacture of nitric acid by the Valentiner process. N. S. TOPSUEV. *J. Chem. Ind. (Moscow)* 5, 494-8 (1928).—The theory of decompn. of NaNO₂ in installations such as those of Valentiner, Hart or Frischer is fairly well known, but the conditions of dissocn. of the acid formed and of absorption of N oxides have not hitherto been studied. These problems were studied with a view of possibly bringing about better yields of HNO₃. Since it is established that the decompn. of HNO₂ is due to heating of the upper part of Valentiner retort above 140° the vapor pipe must be so constructed as to reduce to a min. the condensation of HNO₂ at the top of the retort. As, however, it is impossible completely to prevent the dissocn. of HNO₂, and as the N oxides formed not only reduce the yield of HNO₃ but also contaminate the product obtained, it is necessary to study the conditions of retransformation of the oxides into HNO₃. At temps. below 150° HNO₂ decomposes into NO₂, N₂O₄ and H₂O; above 150° the decompn. yields NO, O and H₂O. This explains the fact that during the first few hrs. of the operation of a Valentiner plant, when the temp. is still comparatively low, the retort contains NO₂ and N₂O₄ aside from HNO₃ and water. As the temp. gradually increases NO and O begin to predominate, and finally NO₂ and N₂O₄ all but disappear. While NO₂ is readily sol. in HNO₃, the soly. of NO in HNO₃, d. 1.4, is only 9.25 at 25°. Thus one may expect, when operating below 150°, that the HNO₃ condensate will be contaminated by N₂O₄, whereas above 150° it will be comparatively free from it. NO, which is poorly absorbed by HNO₃, escapes the condenser and enters the pipe leading to a condenser contg. H₂O, but before it reaches the latter it oxidizes mostly to N₂O₄ and in this form is absorbed by the H₂O with formation of HNO₃ and NO. The H₂O absorption of N oxides continues as long as the concn. of HNO₃ in the H₂O is not great. It follows that it is advantageous to have an empty receiver between the HNO₃ condenser and the condenser containing H₂O, thus giving NO an ample opportunity for oxidation to N₂O₄. It is evident that in order to obtain as pure a condensate of HNO₃ as possible the operation of decompn. of NaNO₂ must be so conducted that the temp. should rise rapidly to 150°, thus shortening the period of formation of NO₂ and N₂O₄. The greater the concn. of NO and O the more favorable are the conditions of oxidation of the former to HNO₃. It is therefore desirable that these gases are not contained in the condensation system in a dil. condition. If air is introduced into the retort one of its effects is favorable, as it supplies O₂ for the oxidation of NO to HNO₃. On the other hand the air is at the same time responsible for the introduction of inert N₂ with diln. of NO and O, thus checking the useful operation. A series of expts. arranged on the decompn. of NaNO₂ while supplying various amts. of air to the retort

has shown that the introduction of air has no essential influence on the N_2O_4 content of the HNO_3 obtained. Tables and diagrams are given. BERNARD NELSON

Process for the extraction of phosphoric anhydride. UGO ORLANDI. *Notiz. chim.-ind.* 3, 343-4 (1928).—The new process is far more economical than earlier processes, such as those of Lilienroth and of Auger-Urbain, which use SiO_2 and C. It is based on the attack of $Ca_3(PO_4)_2$ by SiO_2 in the presence of SO_2 and H_2SO_4 . A mixt. of $Ca_3(PO_4)_2$, SiO_2 and a flux (alk. sulfate, pyrites ash, fused oxide, etc.) is treated with oleum contg. a high proportion of SO_3 . The temp. rises to 300° , and when the reaction is complete, the product is run into an elec. furnace at 600° . At first, SO_2 in the presence of H_2SO_4 reacts with $Ca_3(PO_4)_2$ to form $CaSO_4$ and HPO_3 or P_2O_5 or both, while in the elec. furnace at higher temp. the $CaSO_4$ reacts with SiO_2 , forming $CaSiO_3$ and regenerating SO_3 , the composite reaction being: $Ca_3(PO_4)_2 + 3SiO_2 + 3SO_3 \rightarrow 3CaSiO_3 + P_2O_5 + 3SO$. From the elec. furnace P_2O_5 and HPO_3 sublime at 600° , while evolution of regenerated SO_2 or of SO_2 occurs at about 1000° . The SO_2 serves for the regeneration of oleum. The HPO_3 is hydrated to H_3PO_4 and with NH_4OH this is converted into $(NH_4)_2HPO_4$. For fewer kw. hrs. per kg. of P_2O_5 produced are consumed than in any other process (3.7-4.5 compared to 9-14 kw. hrs. per kg.). The app. is described and illustrated. C. C. DAVIS

The German carbon dioxide industry. A. SANDER. *Z. komp. flussige Gase* 27, 25-7 (1928).—Historical.

Adsorption of sulfur dioxide, present in small percentages in gaseous mixtures, by means of colloidal oxides and of active carbon. CELESTINO PICAI. Reale scuola d'Ingegneria Padova. *Giorn. chim. ind. applicata* 10, 199-203 (1928).—The removal of small proportions of SO_2 from gases is an important industrial problem, e. g., in gas from the heat treatment of steels (cf. 8). Expts. were carried out to ascertain whether gelatinous SiO_2 , Al_2O_3 and active C adsorb SO_2 from gases contg. only a small proportion. If they are effective in this respect their use might be of industrial value. The data, which are recorded in tabular and in graphical form, show that gelatinous SiO_2 has a lower satn. value than Al_2O_3 or active C, but is superior in that it is more easily activated and is cheaper. The technique for their industrial use is essentially the same in each case. With respect to their use for the adsorption, enrichment and utilization of SO_2 in gaseous mixts., gases contg. up to 3-4% SO_2 require so large and costly equipment that it is not economical to recover the SO_2 . It is considered that colloidal oxides and active C are unsuitable for use in the recovery of SO_2 from gases. C. C. DAVIS

Sulfonitrous and sulfonitric mixtures. A. SAINT-GERME AND L. RONDIER. *Compt. rend.* 187, 291-3 (1928). S and R study the dissociation pressure of mixts of H_2SO_4 (55-92%) contg. small quantities of HNO_3 and HNO_2 such as one obtains in the lead-chamber process. The pressure is measured dynamically; the evolved gases are carried off with a stream of N_2 . The decomposition pressure of sulfonitrous mixts. is greater with decreasing concn. of H_2SO_4 . The vapor pressure of HNO_2 in sulfonitric mixts. increases with temp. and as the concn. of H_2SO_4 increases to 78° , decreasing above this concn. Mixts. of sulfonitrous and sulfonitric acids have a pressure higher than the sum of the individual pressures. This anomaly can be explained by the reaction: $SO_2 + HNO_2 + HNO_3 \rightarrow N_2O_4 + H_2SO_4$, causing the liberation of the volatile N_2O_4 . The reaction is displaced toward the right as the concn. of H_2SO_4 is increased. The presence of N_2O_4 is proved by analysis. D. H. POWERS

The development of the potash industry in the Stassfurt district and its present position, with especial reference to the establishment and development of the Kalisya-dikat. PSORTA. *Kali* 22, 151-7, 175-8, 194-8, 209-12, 233-7, 249-53 (1928). E. H.

Calcium nitride. PAUL DUTOT AND ARMAND SCHNORF. *Compt. rend.* 187, 300-2 (1928).—Lengthy studies on the reaction between Ca and N_2 are reviewed. The more finely divided the Ca the more rapid is the reaction. It may be prepd. very finely by dissolving in liquid NH_3 and decomg. the hexamine at low temp. *in vacuo*. Alkali metals and H_2O are not catalysts and O and oxidants are powerful inhibitors. The reaction is autocatalytic and its rate increases to a max. at 450° , dropping very low at 600° and increasing again up to the m. p. of Ca. At high temp. Ca_3N_2 (I) is formed easily and at low temp. there is a 2 to 3% N_2 deficit. The pressure of reheated nitride at once takes a definite value. I formed by heating a long time at 1200° is citron yellow. If it has not been obtained this way, it is black below 350° , blue-black up to 600° , red-dish brown up to 850° , greenish up to 1100° and yellow above 1150° . Each of the nitrides except the yellow form has an irreversible decompn. pressure. It is suggested that an unstable mol. combination, CaN , is formed at low temp. which is irreversibly decomd. on heating. D. H. POWERS

Manufacture of solid zinc chloride. N. N. EFREMOV AND I. YAKIMETZ. Severn Khim. Trust. *J. Chem. Ind. (Moscow)* 5, 345-53(1928).—Russian com. ZnCl_2 is usually marketed as a dark-brown 46 to 47 Bé. soln. contg. 44 to 45% ZnCl_2 . A sample had the following compn.: Zn 20.84, Cl 23.48, SO_3 0.22, Fe 0.06, H_2O 53.40, Ca, Mg and org. matter traces. The dark coloration is due to the latter. An investigation was made to det. if anhyd. ZnCl_2 could be made by the use of open cast Fe evapg. vessels at ordinary pressure, to avoid expensive freight on H_2O . It is known that in the course of such an evapn. a certain amt. of basic salts insol. in H_2O is formed. The compn. of these basic salts is $m\text{ZnCl}_2 \cdot n\text{ZnO} \cdot p\text{H}_2\text{O}$, they are not only in the ppt., but they can also be detected in a colloidal state in H_2O soln. Sometimes on diln. of solns. an addnl pptn. of basic salts takes place. HCl is also formed in the course of evapn., according to the reaction $2\text{ZnCl}_2 + 2\text{H}_2\text{O} \rightarrow \text{Zn}(\text{OH})_2 + \text{ZnCl}_2 + 2\text{HCl}$; when once formed it attacks the vessel with formation of Fe_2Cl_4 at lower and Fe_2Cl_6 at higher temps. By evapg. a com. soln. at various temps., the following results were obtained.

	% Zn	% Cl	% Fe	% in sol. basic salts obtained by treatment with H_2O	% H_2O
200°.....	41.85	44.76	0.10	0.65	12.23
220°.....	42.56	46.23	0.52	0.70	9.57
250°.....	44.21	48.82	0.90	1.59	4.03
280°.....	44.57	49.31	0.97	1.78	2.92
310°.....	44.77	49.59	1.06	1.78	2.34
340°.....	45.20	50.12	1.10	1.94	1.18

Complete dehydration is not obtainable without the use of vacuum, even at much higher temps. The non-removable H_2O is probably fixed in the basic salts only. For practical purposes it is not advisable to continue evapn. after 220° has been reached, since the product thus obtained is very hard on cooling and only contains 9.5% H_2O . If evapn. is continued beyond this point the amt. of H_2O is reduced only at a very considerable expense of fuel and a correspondingly increased attack of the vessel, resulting in an increase of Fe_2Cl_4 . The damage done to the cast Fe vessel from HCl formation is usually insignificant. An investigation showed that the more Si in the cast Fe the better it resists the HCl . Mn, C, P and S in cast Fe have no influence. With cast Fe kettles contg. 6 to 8% Si attack on the vessel is almost unnoticeable. The above figures of Fe_2Cl_4 formation were obtained with cast Fe of low Si content. In redissolving com. solid ZnCl_2 it is advisable to add a calcd amt. of HCl for soln. of a part of the basic salts formed by hydrolysis.

BERNARD NELSON

Dehydrating Glauber salt. P. N. LASHCHENKO AND D. I. KOMPANSKI. *J. Chem. Ind. (Moscow)* 5, 304-7(1928).—The waters of Batalpash lakes in Caucasus, contg. 173.3 g. Glauber salt per l., give by natural evapn. a salt deposit of the following compn.: H_2O -insol. 0.06, loss in wt. at 120° 56.01, Na_2O 19.21, SO_3 24.63, MgO and Cl traces. This shows that the residual salt consists of remarkably pure $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ with a slight admixt. of earthy material. As a result of a search for the most economic method of treatment of this salt to obtain anhyd. sulfate in com. quantities the following procedure, which is as yet in the lab. stage, was adopted. One kg. of the salt is heated on a H_2O bath at 60°. A portion of the sulfate dissolves in its H_2O of crystn., the rest ppts. and is easily decanted. The ppt. is freed from mother liquors by filtration with suction, after which it contains 7.4 to 8.7% H_2O from which it can be freed completely by drying 40 to 45 min. at 60°. The decanted liquid is freed from suspended earthy particles by filtration through paper with suction and left to crystallize. The crystals are chemically pure sulfate, whereas the mother liquors contain Na_2O 3.60, SO_3 4.59, MgO 0.059, Cl 0.035.

P. THOMASSET

Carbon black produced from natural gas in 1927. G. R. HOPKINS AND H. BACKUS. U. S. Bur. Mines, *Mineral Resources of U. S. 1927*, Pt. II, 27-31 (preprint No. 3, published August 16, 1928). E. H.

Vitriol preparation. III. System zinc sulfate-sulfuric acid-water. G. AGDE AND F. SCHIMMEL. *Z. angew. Chem.* **41**, 340-1 (1928); cf. *C. A.* **21**, 2762.—The soly. of ZnSO_4 in aq. solns. of H_2SO_4 at -10° to 39° has been measured, the results showing that the soly. is depressed considerably by the acid. The temps. of transition of the heptahydrate into the hexahydrate in presence of varying amts. of H_2SO_4 have been detd.; some f.-p. data are also recorded. B. C. A.

The utilization of liquid oxygen in railway workshops. J. OUDER. *Engineering* **125**, 694-5 (1928).—Where large amts. of O_2 are used and where good express service is available it may be more economical to replace high-pressure O_2 in steel cylinders by liquid O_2 . The evapn. loss is 0.57% per hr. The railway shops at Montigny-les-Metz obtain the liquid in metal vacuum containers, capacity 55 lb., tare 79 lb., including enclosing metal case, t. c., 1.45 ft. Steel cylinders weigh 8 times the O_2 they contain. Compressed O_2 costs 0.48¢ per cu. ft., liquid O_2 0.28¢, a saving of 44.5%. Evapn. losses and cost of current to vaporize the liquid reduce this to 40%. The method and app. for vaporizing and storing the O_2 are described in detail, including a diagrammatic drawing and a photograph. The gas is stored in a 282.5 cu. ft. tank, at 56.9 lb. per sq. in. pressure and distributed through Fe piping. To prevent leakage through pipe unions a little solder is run into the end of each union. Jenkins valves were found most satisfactory. E. G. R. ARDAGH.

Salt lakes of the Slavgorod region in Siberia. M. I. KUCHIN. *J. Chem. Ind. (Moscow)* **5**, 292-7 (1928). Petukhov lakes, about 210 km. from Slavgorod, are satd. with Na_2CO_3 . They consist of 1 large and several smaller lakes, the latter acting as a sort of natural evapn. basins for the former. When the temp. drops below 0° the smaller lakes ppt. $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ in layers 8 to 15 cm. deep. This Na_2CO_3 is mined and dehydrated by exposure to the sun, yielding a product contg. 99% Na_2CO_3 . The total amt. of the salt dissolved in these lakes is estd. to be 2.6 million tons calcd. as anhyd. Na_2CO_3 . The amt. of the salt pptd. at the bottom of the lakes is about twice this quantity. Analysis of the salt-pptd. soda crystals gave: insol. none, H_2O 62.16, Na_2CO_3 36.46, NaCl 0.39%, Na_2SO_4 trace. In purity the product may be compared with that which ppts. in winter at the bottom of British Columbia soda lakes (*Mining Magazine* **35**, 113 (1926)) and is incomparably superior to the products mined from Californian, Egyptian and East Siberian soda lakes which contain considerable admixts. of NaCl and Glauber salt. Kulundra steppe, also in the Slavgorod district, contains colossal deposits of thenardite and mirabilite. Lake Ushkala, situated in the steppe, has at the bottom a deposit of Na_2SO_4 1-1.5 m. thick. Peechatnui and Lomovii lakes contain NaCl of 90% purity, MgSO_4 and other harmful admixtures being absent. BERNARD NELSON.

Effects of plasticization on the mechanical and elastic properties of natural and artificial substances. II. MAXFRED AND J. OBRIST. *Rev. gén. mat. plastiques* **4**, 67-71, 139-51, 201-13, 335-43 (1928).—See *C. A.* **21**, 2535, 2991; **22**, 173. A. P.-C.

Nitric acid from aluminum nitrate, etc. M. BUCHNER. *Brit.* **283,117**, Jan. 3, 1927. $\text{Al}(\text{NO}_3)_3$ is decompd. by heating *in vacuo* to obtain an increased yield of HNO_3 . Basic Al nitrate is preferably used, to obtain alumina free from Fe. Water or steam may be added to regulate the concn. of the HNO_3 produced.

Apparatus for manufacture of hydrochloric acid and sodium sulfate. EMANUEL V. BENJAMIN (to Myles Salt Co., Ltd.). U. S. 1,681,760, Aug. 21.

Concentrating acid or alkaline solutions or other incrusting or corrosive solutions. PLINIO BRINGHENTI. U. S. 1,682,265, Aug. 28. The soln. is directly heated with a liquid heat-transmitting medium such as melted paraffin which is lighter than the soln. and insol. in it and is introduced as a stream of finely divided material at a temp. below the b. p. of the soln. to be concd. The liquid thus introduced is floated off, entrained soln. is sep'd. from it, the sep'd. liquid is heated by direct contact with a hot

gaseous medium to restore heat lost to the soln.; the heated soln. is sprayed into a vessel whereby it is partly evapd., vapors evolved are carried off and the partly concd. soln. is returned to the cycle for further concn. by the finely divided heated liquid. An app. is described.

Alkali hydrides. DEUTSCHE GOLD- UND SILBER-SCHNEIDANSTALT VORM. ROESSLER, H. FREUDENBERG and H. KLOEPFER. Brit. 283,089, Sept. 28, 1927. In reacting on alkali metals with H, the metal is introduced into the reaction chamber in finely divided form, *e. g.*, by spraying the molten metal with a stream of H or of inert gas or vapor. The reaction chamber may contain inert solid materials such as NaCl, Fe powder, Na_2CO_3 or charcoal, and the reaction is carried out at 180–250° or higher and may be effected under pressure.

Nitrates of aluminum and other metals. M. BUCHNER. Brit. 282,772, Dec. 24, 1926. Aluminiferous materials such as clay or bauxite or ores of other metals such as Zn or Ce are treated with HNO_3 in vessels formed of acid-proof alloy (such as an alloy of Fe, Ni and Cr or W) with gradual increase of temp. and pressure. A final temp. of 150–160° is suitable and an excess of aluminiferous material is preferably used to facilitate pptn. of any Fe present.

Phosphate and aluminate. RHEINLANDE KUNSTHEIM VEREIN CHEMISCHER FABRIKEN A.-G. Brit. 283,072, June 24, 1927. Al phosphates are decompd. by heating to 900° or higher with alkali salts and alk. earth compds. such as oxides, carbonates, sulfates or chlorides. The product is extd. with water to sep. alkali aluminate (from which alumina may be prepd.) and to leave a phosphate which is sol. in NH_4 citrate and may be used as a *grith er*. Steam may be passed over the mixt. during the heating and may be introduced into the flame used for heating.

Treating aluminum-bearing minerals. WM. G. BLOK TILT. U. S. 1,681,921, Aug. 28. Al-contg. minerals such as clay or bauxite are heated with $(\text{NH}_4)_2\text{SO}_4$ (suitable to a temp. of about 315°) and the Al is brought into soln. and then pptd. with $(\text{NH}_4)_2\text{SO}_4$ to obtain basic Al sulfite which may be calcined to form Al_2O_3 .

Aluminum and potassium compounds from leucite, etc. P. SPENCE & SONS, LTD., AND T. J. I. CRAIG. Brit. 283,087, June 29, 1926. A substantially neutral soln. obtained from leucite or similar materials by treatment with HNO_3 or a soln. rendered basic by heating to drive off some free and combined HNO_3 or by treatment with potash or alumina, is subjected to regulated cooling to effect selective cryt. of KNO_3 only; $\text{Al}(\text{NO}_3)_3$ is then sep'd. from the remaining soln. by adding HNO_3 and the remaining liquor is preferably used for treating a fresh batch of mineral on the counter-current principle. Fe may be pptd. from the soln. either before or after sep'n. of KNO_3 , either as a basic ferric K sulfate by heating in the presence of Al or K sulfate and insol. material such as leucite residues, or by digestion with an oxide of Mn, Sn or Sb. Various other details and modifications are also given.

Ammonium sulfate. SOC. ANON. DE MATERIEL DE CONSTRUCTION. Brit. 282,755, Dec. 29, 1926. CaSO_4 is decompd. by $(\text{NH}_4)_2\text{CO}_3$ to form $(\text{NH}_4)_2\text{SO}_4$ in the presence of clay, kaolin, bauxite or other substances contg. SiO_2 , Al_2O_3 and Fe_2O_3 so that the residue after sep'n. of the $(\text{NH}_4)_2\text{SO}_4$ formed is suitable for use in making *portland cement*.

Refining crude arsenic trioxide. CHESTER L. READ (to American Smelting & Refining Co.). U. S. 1,681,496, Aug. 21. The crude As_2O_3 is volatilized and passed over a substance such as vitreous As oxide which will absorb impurities. An app. is described.

Treating raw calcium phosphate. F. G. LILJENROTH. Brit. 282,704, Dec. 31, 1926. Raw Ca phosphate is treated with H_2SO_4 and the CaSO_4 is sep'd., mixed with sand, clay and bauxite, and calcined in an oxidizing atm. preferably with coke to facilitate evolution of SO_2 from which H_2SO_4 may be prep'd.; or the raw phosphate may be leached with an acid having a sol. Ca salt such as HNO_3 or H_3PO_4 and CaSO_4 pptd. by sulfate of NH_4 or of an alkali metal. Residues may be obtained in similar treatments which may be used as a cement clinker material. SiF_4 may be led into a suspension of the Ca phosphate to form SiO_2 and HF or H_2SiF_6 which further react to give H_3PO_4 and CaF_2 . Various other modifications are described.

Calcium nitrate. J. BRIGHTMORE. Brit. 283,232, July 6, 1926. Ca compds., preferably a mixt. of hydrated lime with 10% of calc. spar, are subjected under pressure in a closed chamber to the action of air (which may be preheated to about 500°), superheated steam and an elec. current, to form $\text{Ca}(\text{NO}_3)_2$. Catalysts such as Cu and Ni may serve as electrodes.

Purifying sodium stannate solution. CHESTER L. READ and BERRY M. O'HARRA (to American Smelting & Refining Co.). U. S. 1,681,497, Aug. 21. Pb and Cu are

removed by the action of Na sulfide; Sb, Se and Te are then removed by the action of Sn in an oxidizable condition such as by SnCl_2 or metallic Sn and by heat, so that the Pb and Cu may be recovered separately from the Sb, Se and Te.

Tungstic oxide gel. WALTER A. PATRICK (to Silica Gel Corp.). U. S. 1,682,239, Aug. 28. A 3-7% soln. of Na tungstate is added to an acid such as HCl or H_2SO_4 with thorough stirring until the quantity of Na tungstate added results in a final concn. of H ions resulting from the acid in the mixt. of 0.1-0.5 mols. per l. The product is dried and is hard and transparent.

Stannic oxide gel. WALTER A. PATRICK (to Silica Gel Corp.). U. S. 1,682,240, Aug. 28. A sol. stannate such as Na stannate is added to an acid soln. such as HCl or H_2SO_4 with thorough stirring until a H ion concn. of 0.1-0.5 mols. per l. is attained; the mixt. sets to a hydrogel after a time and this is washed to remove acid and salt, dried at 75-120° to drive off part of the moisture and the temp. is then slowly increased to drive off the greater portion of the remaining moisture.

Aluminum oxide gel. WALTER A. PATRICK (to Silica Gel Corp.). U. S. 1,682,241, Aug. 28. A 3-7% soln. of Na aluminate or other suitable sol. aluminate is added, with thorough stirring, to an acid soln. such as HCl or H_2SO_4 until a H-ion concn. of 0.1-0.5 mols. per l. is attained. The product may then be dried at 75-120° and subsequently at 300-400°.

Titanium oxide gel. WALTER A. PATRICK (to Silica Gel Corp.). U. S. 1,682,242, Aug. 28. A colloidal soln. of titanium acid is allowed to set to a hydrogel, and the latter is dried in a current of air at 75-120° and the temp. afterward slowly increased to 300-400°.

Zinc oxide. SOC. GENERALE D'ETRAIQUES ET FUSORIES, Brit. 282,706, Dec. 30, 1926. A sintered ZnO which contains sides of Fe or Cu and is suitable for reduction in a "zinc oven" is obtained by roasting in a sintering app. operated with a blast, a mixt. of ZnSO_4 and a salt such as a zinc blende, iron pyrites or Fe and Cu pyrites. Carbonaceous material, roasted blende, sintered material or slag from iron or Cu blast furnace may be added to the mixt. before roasting.

Active carbon and carbon disulfide. I. G. FARBENIND A. G. Brit. 283,267, Oct. 5, 1926. C is activated and CS_2 produced by treating heated C with vapor of S or of a compd. yielding S.

Carbon black. CHATELAIN MATLOCK (to Monroe Louisiana Carbon Co.). U. S. 1,681,945, Aug. 28. An app. for producing C black from hydrocarbon gas comprises a furnace, gas burners within the furnace and a mixing app. connected with the burners and adapted for mixing air and gas in proportioned quantities insufficient for complete combustion, by positive agitation, before the gas is supplied to the burners.

Zirconium. THE ALLOY MANUFACTURING COMPANY. Fr. 635,088, May 27, 1927. Zr compds. are obtained from silicozirconates of Zr by dissolving the ore with acid, e. g., H_2SO_4 or oxalic acid, and pptg. the Zr by the addn. of K compds. and cooling. The double salt of Zr and K is calcined, giving ZrO_2 .

Catalysts for the preparation of hydrogen and alcohol. RENÉ JEAN AUGUSTE GRENIER. Fr. 634,747, May 20, 1927. See Brit. 2,723 (C. 1, 22, 1658).

Bleach liquor as a by-product in salt purification. VICTOR YNGVE. U. S. 1,683,431, Sept. 4. A brine contg. Me and Ca is mixed with NaOH in excess of the quantity necessary to ppt. the Me and Ca, the mixt. is heated to a temp. of about 100° and the pptd. hydroxide sludge is sep'd. and is chlorinated only to the extent that no appreciable amt. of Mg(OH)_2 is chlorinated.

Use of fused salts such as sodium carbonate or barium chloride as oxidation preventives and lubricants in making brake drums or other drawn metal articles. JOSEPH E. BATHIE (to Kelsey Wheel Co.). U. S. 1,683,117, Sept. 4.

Apparatus for separating graphite by flotation. CAMILLE FRÉDÉRIC LANOUÉ. Fr. 634,791, Dec. 7, 1926. Two reservoirs are provided, the substances of higher density than graphite being sep'd. in the first reservoir, and the substances of lower density in the second.

Matrix for printing plates. EUGEN R. THOMPSON (to John S. Stokes). U. S. 1,681,447, Aug. 21. A non-metallic backing or body which may be formed to synthetic resin and cementitious material carries a type forming face of sprayed metallic particles.

Rust-resisting iron and steel printing plates. RUDOLF FRITSCHÉ. U. S. 1,681,949, Aug. 21. A lithographic plate is formed with a chrome steel body having one surface of a grained porous formation such as may be produced by use of HF or HNO_3 and HCl.

Packing material. OLIVER T. HUNGERFORD. U. S. 1,681,540, Aug. 21. Fibrous material recovered from flax straw by boiling it with NaOH soln. is mixed with another

harder, flexible, resilient material such as sisal fiber or tougher portions of the flax straw.

Making balls or pellets of readily fusible substances. C. E. LINEBARGER. Brit. 282,994, Jan. 17, 1927. Substances of relatively low m. p. such as a mixt. of chlorinated naphthalene, stearic acid and carnauba wax are melted and streams of the molten material are allowed to flow through a body of CaCl_2 soln. or other suitable liquid which is at a temp. higher than the m. p. of the material under treatment, and the drops thus formed are then passed through liquid of lower temp. to effect solidification. An app. is described.

Sound-record composition. FRANK E. LAYMAN and LINWOOD T. RICHARDSON (to Cutler-Hammer Mfg. Co.). U. S. 1,682,913, Sept. 4. A resin of the "S-treated type" such as may be formed from phenol or C_{10}H_8 and S chloride is mixed with approx. 10% its wt. of white lead and the mixt. is heated for about a half hr. at a temp. above 150° .

Sound-absorbing plaster containing porous granular particles such as pumice. LYL B. RYMARCZICK. U. S. 1,682,986, Sept. 4.

Flexible sponge rubber cores for use in casting loud speaker amplifying horns of plaster of Paris, etc. FRED W. TEMPLE (one-half to William P. Crockett). U. S. 1,682,691, Aug. 28.

Heat-sensitive recording material for copying telegraph apparatus or the like. R. S. BICKNELL and R. H. RASCHER (to Marconi's Wireless Telegraph Co., Ltd.). Brit. 282,759, Dec. 31, 1926. A material such as short fibered paper is coated with a compn. which changes color when heated, e. g., by the action of an elec. spark. Suitable compns. are: (a) an aq. soln. of gelatin, salt and phenolphthalein, (b) an aq. soln. formed of aniline HCl , gelatin and KNO_3 , or other suitable oxidizing agent, (c) nitrates such as those of Ni, Cu, Mn and Ir, alone or with other salts such as nitrates or thio-sulfates or double salts or nitrites.

Polishing and hardening the contact surface of commutators. WM. L. WEBER. U. S. 1,682,157, Aug. 28. The surface to be treated, while traveling at high speed, is treated with a compn. comprising S and an abrasive material under sufficient pressure and heat to polish the surface and cause the S to unite with the metal of the surface and harden it.

Removing and recovering volatile plasticizers from celluloid and similar compositions. HARRY P. BASSETT. U. S. 1,681,692, Aug. 21. The material is treated in the presence of an acid such as very dil. HNO_3 which is insufficient in quantity to cause carbonization or decompn., at a temp. of about 100° , with a current of steam to drive off volatile plasticizing substances such as camphor and the latter are recovered by condensation.

Heat treatment of wood chips, sawdust or other materials by use of molten metal. JOHN S. MORGAN (to Thermal Industrial and Chemical Research Co. (T. I. Co.), Ltd.). U. S. 1,681,808, Aug. 21. In treating materials such as sawdust or wood chips in a bath of molten metal, with production of a solid residue of lower sp. gr. than the molten metal, the solid residue is removed from the surface of the molten metal substantially free from the metal by causing accumulated residue on the surface of the metal to be entrained in a stream of steam or distn. products or other suitable elastic fluid moving upwardly through a duct over the residue. An app. is described.

Apparatus for centrifugal casting of dental inlays, etc. CHESTER P. SHOUDY (to Shoudy Mfg. & Developing Co.). U. S. 1,683,207, Sept. 4.

Imitation paintings. HUGO GABLER-ADLERSELD. U. S. 1,682,261, Aug. 28. A transparent support such as a glass plate is coated with a layer of transparent substance, e. g., collodion, and then with chromated gelatin which does not contain any solid particles of pigment; the latter is exposed to the action of light under a photographic negative, developed and dried, and paint is applied to the diapositive thus obtained; after drying of the paint a sheet of tough flexible material such as textile fabric is secured on the layer of paint and the picture is finally pulled off from the transparent support.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

C. F. LARTON, C. H. KERR

Applications of glass to the chemical and allied industries. A. B. MARSHALL. Corning Glass Works, Baltimore, Md. *J. Soc. Chem. Ind.* **47**, 243-77 (1928). E. H.

Colored glasses. W. M. HAYES. *J. Soc. Chem. Ind.* **47**, 192-6T (1928).—Glasses may be considered as "congealed liquids" indicating an increase in viscosity as the liquid is cooled until it goes solid. The increase in viscosity slows up the speed of crystn. so that the glass is solid before it can deaerate but all glasses will crystallize at a suitable temp. No glass is recommended to produce unless it may be made below 1450° as the materials to contain the melt cannot stand up to higher temps. The properties of glass depend upon its composition. With over 20% soda it will rapidly dim in moist air and CO₂. The material for glass must be finely ground and be intimately mixed and some glass added of similar composit. to that about to be produced. Water is expelled up to 300°, lithium nitrate melt at 320°, red lead loses O and forms litharge at 500°, the litharge melts at 780°, CaO decomposes at 825°; alkali carbonates melt at 800-900° and at 900° most constituents except SiO₂ are liquid. Because of the high viscosity trapped air cannot escape. Careful selection of raw material reduces duration of the fusion period. Elevation of temp. decreases viscosity, but increases the size of the air bubbles. It causes convection currents but corrosion is also increased and the longer the fusion constituents produces fresh bubbles. Colored glasses are usually made by fusing. A flashed glass has a thin coating of intensely colored material upon a colorless base. The colors imparted to glass by oxides corresponds to salts of the transition metals, e.g., iron gives blue. Mn a violet, Cr a yellow color, other colors and combination for color are given. Spectacle glass usually contains rare earths. Whereas the color of oxidized batches is due to colored silicates, in reduced glass it is due to colloidal tint.

Nickel mirrors by the nickel carbonyl method. COLIN G. FINK AND WALTER G. KING, JR. *Trans. Am. Electrochem. Soc.* **54**, (preprint), 4 pp (1928). Ni(CO)₄ was decompd. in contact with heated glass surfaces, producing perfect mirror deposits. Foreign gases, such as air, must be absent, as otherwise dark spots develop in the mirror. Best results were obtained with films 1000 Å. at 180° to 200°. Other materials besides glass were thus coated with Ni. The perfect reflectivity of the Ni mirror is almost equal to that of a Ag mirror. The deposit has a high elec. cond., adheres tenaciously and is tough and resistant. The deposit may serve as a foundation for the electrodeposition thereon of Cr, Cu and other metals.

Fused silica and its use in the chemical industry. AN. MATAGRIN. *Rev. chim. ind.* **37**, 85-9, 124-3, 178-82 (1928).—A review of the history of fused silica, the modern methods of manuf. and uses in chemistry.

The commercial development of a kaolinic fire brick. F. H. NORTON. *Mass. Institute of Tech. Tech. Reports* **11**, 109-85 (1928).—Great shrinkage of Georgia clay necessitates firing at over 2000° C. A light wt. brick for marine boilers and a dense refractory for glass tanks were developed. Properties of these 2 are compared with other high-grade brick.

The testing of a red quarry floor tile kiln. W. HARRY VAUGHAN. *J. Am. Ceram. Soc.* **11**, 659-78 (1928).

Study of china bodies of the Belleek type. JAMES F. COLLINS. Ohio State Univ. *J. Am. Ceram. Soc.* **11**, 706-12 (1928).—A system of compns., frits and firing temps. were studied. The value of previously fritted, or at least calcined, flux for porcelain is proved. Other desirable properties were good dry strength, extreme toughness when fired, moderate firing temp. cone 7 and self-glazing at cone 8. Ivory color is due either to the action of bone ash on the FeO or to the attack of the previously fused flux on the FeO and Fe₂O₃ in the clays. Translucency is due to soln. of the ball fused flux on the FeO and Fe₂O₃ in the clays. Translucency would also contribute to clay by the previously fused flux. Undissolved bone ash would also contribute to translucency. Replacing part of the fluxes by K feldspar would reduce warpage.

Suspension of glazes and barium carbonate water. P. WM. LEE. *J. Am. Ceram. Soc.* **11**, 713-4 (1928).—Heavy settling, fine grinding, raw clay, HCl, AcOH and corn starch are discussed for glaze suspension. *Terra cotta bodies* are held in suspension better if 0.7 to 1.0% wilkinita (a better grade of bentonite) is added to the BaCO₃ used for suspension.

Production and uses of stoneware chemical plant. I. B. M. PEARSON. *Chem. Age* (London) 19, 98-9(1928). II. *Ibid* 117-8. III. *Ibid* 159-60. E. H.

Progress in ceramics in 1927. M. MIELDS. *Chem.-Ztg.* 52, No. 67, Fortschritts-ber, No. 3, 92-102(1928). H. H.

Equations and tables for shrinkage, expansion and design calculations. A. E. R. WESTERMANN. Univ. of Ill. *J. Am. Ceram. Soc.* 11, 715-23(1928). C. H. KERR

A laboratory for the technical control of the manufacture of refractories. L. J. TROSTEL. *Bull. Am. Ceram. Soc.* 7, 260-7(1928).—The lab. of the General Refractories Co. at Baltimore, Md., is described. C. H. KERR

Enameling, with special reference to modern enameling ovens. A. BRESSER. *Korrosion Metallschutz* 4, 157-60(1928).—A discussion of the construction of modern enameling ovens with sketches showing the different types of firing. E. E. ROETHLI

Continuous enameling furnace. W. O. OWEN. *Bull. Am. Ceram. Soc.* 7, 272-6(1928).—A surface-combustion furnace is described. C. H. KERR

Apparatus for a rapid sedimentation analysis (VAN NIEUWENBURG, SCHOUTENS) 1. **CaCl₂ waters** (LANE) 14. **Analysis of bauxite and refractories of high alumina content** (LUNDELL, HOFFMAN) 7. **Ladle lining** (U. S. pat. 1,681,913) 9.

BERGE, AUGUST. **Keramisches Praktikum.** 2nd ed. Anleitung zu keramischen Laboratoriumsarbeiten auf chemischer Grundlage für Studierende und Techniker der keramischen Industrie. Halle (Saale). W. Knapp.

TURK, KARL. **The Ready Remedier. A Manual for porcelain enameling superintendents.** Baltimore, Md. Waverly Press. 121 pp. Reviewed in *Western Soc. Eng.* 33, 157(1928).

Glass. LOUIS-JOSEPH MARCHAL. Fr. 634,847, May 23, 1927. Cylindrical and other shaped articles of glass are made in molds revolving at a high speed, into which the melted glass is run.

Glass. C. TRENTIN. Brit. 282,768, Dec. 31, 1926. A glass suitable for lab ware, which resists attack by boiling water, contains a high proportion of SiO₂ (preferably about 75%) together with B oxide, Al oxide and Zn oxide. A suitable batch may be formed from silica 72, borax 0.625, Na₂CO₃ 18, K₂CO₃ 3, NaNO₃ 1.5, Al₂O₃ 0.25, ZnO 0.3 and CaCO₃ 18 parts.

Optical glass. ROBERT J. MONTGOMERY (to Bausch & Lomb Optical Co.). U. S. 1,681,704, Aug. 21. Optical glass which cuts off objectionable yellow rays is formed from a batch comprising SiO₂ 69.5, Na₂O 15.8, B₂O₃ 0.3, cerium didymium oxide 12, Sb oxide 1.9 and As oxide 0.5 parts.

Apparatus for forming glass sheets or plates. W. ZIMMERSTADT (to Naamlooze Venootschap Maatschappij tot Beluor en Exploit van Octrooien). Brit. 282,756, Dec. 30, 1926.

Apparatus for surfacing plate glass. JOHN H. FOX (to Pittsburgh Plate Glass Co.). U. S. 1,683,342, Sept. 4.

Apparatus for making hollow glass articles. GEORGE A. MILLAR (to Cooper Hewitt Electric Co.). U. S. 1,681,591, Aug. 21.

Glass-making furnace. CHARLES ROYER. Fr. 634,808, May 16, 1927. Constructional features.

* **Method of using polarized heat rays for detecting strain in glass or other materials which transmit heat rays.** JESSE T. LITTLETON, JR. (to Corning Glass Works). U. S. 1,681,991, Aug. 28.

Ceramic ware from shale. HALVER R. STRAIGHT. U. S. 1,682,200, Aug. 28. Granulated shale is piled in an upright stack with its bottom and side edges sealed and the central and bottom portion of the pile is stirred and steam under pressure, in excess of the quantity which is condensed, is introduced. This treatment serves to remove air and prep. the material for molding.

Tunnel kiln for baking ceramic ware. VICTOR SELLEZ. U. S. 1,683,300, Sept. 4.

Tunnel kiln suitable for burning ceramic ware. JAMES KELLEHER (to Harper Electric Furnace Corp.). U. S. 1,681,939, Aug. 28. Connections are provided for circulating a cooling medium such as water through hollow rails which serves to prevent undue expansion and warping.

Fused silica. L. B. MILLER (to British Thomson-Houston Co., Ltd.). Brit. 282,733, Dec. 20, 1926. Cloudy or milky quartz crystal is converted into clear vitreous silica by heating near to, but not above, 1700°, then cooling to below 270° and finally

fusing *in vacuo* in an elec. furnace such as that described in Brit. 240,489. The product may be extruded in the form of rods or tubes.

Fused silica. QUARTZ ET SILICE. Brit. 283,148, Jan. 5, 1927. Sand is packed around a C rod which is raised to a high temp. by the passage of an elec. current. An oxidizing atm. is maintained in the furnace during the melting of the silica to obtain a product which does not contain either free C or Si. Air or O may be supplied to the furnace but a small quantity of water is preferably added to the sand before introduction into the furnace.

Fused silica articles. QUARTZ ET SILICE. Brit. 283,174, Jan. 6, 1927. In producing pressed articles of fused silica, a silica blank is heated up to the temp. at which the material volatilizes freely and then transferred quickly to the press. Various ails of app. are described. Cf. C. A. 22, 2040.

Abrasive articles. DUANE E. WEBSTER (to Norton Co.). U. S. 1,681,891, Aug. 21, 1927. Abrasive grains such as cryst. Al_2O_3 or SiC are mixed with a vulcanizing agent such as S and with rubber latex having a total rubber content of not less than 30% by wt., the mixt. is shaped to the desired form for making grinding wheels or other articles and is then dried and vulcanized. Cf. C. A. 22, 1024.

Abrasive stones. JOHN L. WELLER. U. S. 1,682,649, Aug. 28, 1927. A material such as a natural abrasive having substantially the desired grinding qualities of the finished stone is crushed to a coarse aggregate, and mixed with a plastic binder such as a cement mixt. which also when set will have approx. the same desired grinding qualities, and molded grinding wheels or other articles are formed of the mixt.

Refractory articles. FRANK H. RIDDLE (to Champion Porcelain Co.). U. S. 1,682,249, Aug. 28, 1927. A raw batch for making furnace linings or other refractory articles comprises a mixt. of refractory granules such as sillimanite, clay and sufficient quantity of alumina to combine with substantially all of the silica of the clay to form sillimanite. U. S. 1,682,250 specifies a raw batch for making spark plug insulators or other ceramic articles, comprising uncombined alumina, clay and a flux, the alumina being in such condition and quantity that it will combine with the other materials to form Al silicate upon firing. U. S. 1,682,251 specifies a raw batch suitable for making cooking ware, elec. insulators, etc., contg. andalusite, Zr silicate, clay and fluxing materials such as mixts. contg. 40% of alk. earth oxide.

Refractory products of zirconia, etc. DEUTSCHE GOLD UND SILBER-SCHNEIDEN-STALT VORM. ROESSLER. Brit. 282,795, Dec. 27, 1926. Dry zirconia is mixed with small proportions of hydrolyzable substances such as $ZrCl_4$, $AlCl_3$ or $MgCl_2$ and with water to form a plastic mass which is shaped and burned. Thoria or other suitable substances may be added.

Enamels. I. KREIDL. Brit. 283,130, Jan. 4, 1927. Synthetically prod. Al alkali silicates or Al alk. earth silicates are used as opacifying agents for enamels, glazes, etc.

Oven for continuous enameling of wire. C. L. HEISLER (to British Thomson-Houston Co., Ltd.). Brit. 282,740, Dec. 29, 1926.

Decorative effects on enameled goods. "SPINX" SPOJENÝ SMALTOVNÝ A TOVÁRNÝ NA KOVOVÉ ZBOŽÍ, PŘE. SPOL. Fr. 634,069, May 19, 1927. Drops of solus or glazing or mixts. of the 2 are applied to ceramic objects before glazing and burning or after glazing and before burning to produce decorative effects.

Apparatus and continuous system for coating metallic articles with glass or porcelain enamel. ALVIN G. SHERMAN and ALBERT MEADOWS (to Detroit Vapor Stove Co.). U. S. 1,681,440-1, Aug. 21, 1927.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Report of Committee C-1 on Cement. P. H. BATES, *et al.* *Proc. Am. Soc. Testing Materials* 1928 (preprint) 46, 68 pp. — This report presents data and discussions of co-operative tests of 32 cements by a no. of labs. A S. T. M. standard tests, compression tests on 2-in. cubes, and tension tests on neat cement mixed with 42% water, by weight of the cement, were made by 47 labs., concrete tests by 6 labs., and chem. analyses by 5 labs. Variations in the results from different labs. were great enough to demonstrate the necessity for careful adherence to standard procedure in all details of testing. None of the 3-strength tests used possessed a marked advantage over the others as a criterion of concrete strength.

RAYMOND WILSON

The processes of cement burning in the rotary kiln. ERNST RISSEL. *Tonind. Ztg.* 52, 1237-9(1928); cf. E. S. and W. A. Ernst, *C. A.* 21, 1173.—Analytical results are given for the materials at different points in the rotary kiln including CO_2 . The burning is divided into 5 steps: drying the raw material, heating to the point of decomposition of CaCO_3 during which the last traces of H_2O and first traces of CO_2 are driven off, calcining, calcining to sintering, and sintering. F. O. ANDEREGG

Portland jurament. HERBERT KIEBS. *Tonind. Ztg.* 52, 1384-5(1928).—Portland jurament is made by grinding portland cement clinker, blast-furnace slag and oil-shale cinders. It weighs about 1 kg. per l., whereas portland cement weighs about 1.4 kg.; so that due allowance must be made when it is measured by vol. When measured by wt. the jurament compares favorably with portland cement in strength as detd. according to the German specifications. A greater resistance to MgCl_2 soln. is claimed for jurament. F. O. ANDEREGG

Sea water-resistant cements. GEORGE J. FERTIG. *Concrete (Mill Section)* 33, No. 3, 105-10(1928).—The addn. of granulated slag to concrete mixts. increases their resistance to Mg sulfate. Cf. *C. A.* 22, 2450. RAYMOND WILSON

The resistance of portland cement concrete to the action of sulfate waters as influenced by the cement. D. G. MILLER. *Public Roads* 9, 82-7(1928).—See *C. A.* 22, 3506. L. B. MILLER

A study of concrete pavement from core drill records. C. E. FOSTER. *Roads and Streets* 68, 305-8(1928).—F. draws conclusions concerning the prepn. of the subgrade, segregation, presence of porous mortar and variation in thickness of the pavement from core drill records. L. B. MILLER

Wear tests of concrete. HAROLD ALLEN. Kansas State Agr. Coll. *Concrete* 33, No. 3, 43-7(1928).—Concrete spheres of 9 in. diam. were tested in a paving-brick rattler. The concrete was in most cases moist cured 28 days and air-dried 32 days before test. The French coeff. of the coarse aggregate does not materially affect the resistance to wear of the concrete. Different brands of cement produce concrete of different wearing quality. The use of a surface hardener (Zn Mg silosilicate) increases resistance to wear. Proper curing is necessary to produce wear-resistant concrete. Excessive mixing water affects resistance to wear in about the same proportion as it affects the strength. Replacing more than 1% of the portland cement with natural cement will reduce both strength and resistance to wear in proportion to the amt. of portland cement replaced. RAYMOND WILSON

The determination of the proportions of constituents in concrete. L. G. CARMICK. Bureau of Mines, *Public Roads* 9, 88-9(1928). The proportions of cement, sand and stone in concrete are calcd. from chem. analysis. L. B. MILLER

Decorating concrete. MAXIMILIAN TOCH. *Concrete* 33, No. 3, 31(1928). Some practical instructions are given for decorating concrete in polychrome effects, methods of preliminary treatment of the concrete and a list of suitable pigments. R. W.

Staining and efflorescence on Indiana limestone caused by moisture seepage through backing masonry materials. LEE HUBER. *Proc. Am. Soc. Testing Materials* 1928 (preprint) 90, 12 pp.—Efflorescence on limestone usually consists of the sulfates, carbonates and chlorides of Ca, Mg, Na and K. Evapn. at the surface of the limestone causes a concn. of small quantities of sol. salts present in the mortar, the backing materials or the soil. Under some conditions crystn. occurs below the surface, causing spalling. Staining of the buff Indiana limestone results from a reaction between alk. soln. from the mortar and org. matter in the stone. Both staining and efflorescence are best prevented by following construction practices which prevent seepage of water through walls during and after construction. None of the 22 com. waterproofers tested was entirely effective in preventing staining or efflorescence. Stains tend to disappear on weathering. They can be removed by blasting the surface with steam at 125- to 150-lb. pressure, and immediately treating it with 5% soln. of formic acid, or by successive treatments with a poultice contg. Na carbonate and one contg. formic acid. RAYMOND WILSON

Road maintenance and progress. A review. E. H. COLLCUTT. *Munic. Eng. Sanit. Record* 81, 179(1928). C. H. BADGER

Artificial stones of clay and lime. PETER P. BUDNIKOV. *Tonind. Ztg.* 52, 1309-70(1928).—Cubes made of clay and 10% CaO heated in an autoclave for 8 or 10 hrs. at 10 atm. had a compression strength of more than 100 kg. per sq. cm. F. O. A.

Cold bitumen emulsions. G. S. HAY. *Munic. Eng. Sanit. Record* 81, 86-7, 117-8, 140-1(1928).—The hot bitumen process requires expensive equipment, skilled labor and chem. control. The ductility and elasticity of the bitumen is destroyed by too high or too prolonged heating. A comparatively hard bitumen must be used to

prevent softening in summer with the consequent appearance of waving. Twice as much is needed as will bind the stone and this being brought to the surface by rolling together by a very thin coating of bitumen which after consolidation forms a solid mass of stone. A bitumen emulsion is a suspension of bitumen in water. Emulsions are made by incorporating emulsifiers such as soap, casein, starch, glue, gums and petroleum acids or colloidal clays, slurries, seaweeds, etc., with or without alkali to form a key between the tar or bitumen and the water. Less amts. of emulsifiers are needed when a high-speed colloidal mill is used. Solvents such as paraffin and trichloroethylene are sometimes used but these make it more costly. Types of emulsions are (1) coal tar (2) coal tar mixed with petroleum bitumen, (3) petroleum bitumen and light petroleum distillates such as kerosene or naphtha and (4) pure petroleum bitumen. (1), (2) and (3) are deceptive since the road may appear perfectly good for 5 to 6 months

C. H. RADGER

A new moist-closet and storage tank apparatus. D. O. WOOLF. *Bur. Mines. Public Roads* 9, 90 2(1928).—An improved moist-closet and storage tank are described for use in testing cement.

L. B. MILLER

Mechanism of the action of wood-preserving agents. DEHNST Z. anorg. Chem. 41, 355-8(1928).—To test Batman's theory (cf. C. I. 14, 1023) that the fungicidal action of coal-tar oil or creosote oil is due to the low-boiling hydrocarbons and the high-boiling tar acids and bases and is not influenced in any way by the 40% of neutral oil usually present, a very pure German coal-tar oil was freed from acids and bases and sepd. into several fractions by distn. and the action of the various products on 4 of the ordinary varieties of wood fungus was examd. All the products obtained had a strong fungicidal action on *Polyporus vaporarius* and *Coniophora cerebella*, but the neutral oil boiling above 288° had little action on *Lenzites abietina* and *Fomes annosus*, although the remainder of the oil and a strong fungicidal action on these varieties.

$(\text{NH}_4)_2\text{SO}_4$ [for use in making portland cement] (Brit. pat. 282,755) 18.

Dolomite cement. FREDERICK W. BROWN (one-half to Gideon R. Austin). U. S. 1,682,479, Aug. 28. Dolomite substantially free from iron and silica is rapidly heated to about 760° and further heated at a temp. up to about 870° for a time sufficient to calcine and hold the MgO content but insufficient to calcine the Ca content. The resultant product may be dyed in a water bath and may be used with MgCl_2 soln.

Rotary cement kiln. G. MARTIN. Brit. 282,868, Sept. 27, 1926. The output of a rotary cement kiln is increased by passing the gases through the kiln at greater than the usual speed. A speed of 30 ft. per sec. is preferably maintained in the clinking and decarbonating zones, and a speed of 22 ft. per sec. in the drying zone.

Laying and vibrating layers of concrete for pavements. FRANK W. SAMPSON. U. S. 1,682,687, Aug. 28. Mech. features.

Waterproof cementitious composition. JOHN D. CARTER. U. S. 1,681,570, Aug. 21. CaCO_3 is mixed with approx. an equal wt. of a Na silicate soln of 30-40° B ϕ in which the ratio of the Na_2O to the SiO_2 is about 1:2. The product may be used as a paint or mortar or for surfacing roadways, etc.

Glazing stone and similar surfaces. K. STOLL. Brit. 282,786, Dec. 29, 1926. Stone, artificial stone, pottery or the like are coated with urea-formaldehyde resin, preferably with another material such as a phenol-formaldehyde resin, with which pigments and other ingredients may also be admixed.

Casting artificial stone. FREDERIC M. EMERSON (to Emerson & Norris Co.) U. S. 1,681,727, Aug. 21. A sand mold is treated with irregularly arranged granular particles such as coloring material and cement to form a roughened surface corresponding to a revealed surface of artificial stone to be cast in the mold and the mold surface is spattered or sprayed with paraffin commingled with an oily fluid such as kerosene prior to casting a cementitious compn. in the mold.

Coating artificial stone slabs, etc., with glycerolphthalic anhydride resins and like compositions. L. E. BARRINGER (to British Thomson-Houston Co., Ltd.). Brit. 282,810, Dec. 29, 1926.

Imitation marble finish on hard surfaces. LLOYD V. CASTO (to Oxford Varnish Corp.). U. S. 1,682,067, Aug. 28. A ground coat is applied to the surface to be finished from a positive C resist of the marble surface and an etched printing surface prepd. from a positive C resist of the marble surface to be simulated is used to make transfers of different colors, each successive transfer being of a pigment of darker color than those used in the preceding transfers.

Road composition. SAMUEL S. SADTLER (to Amiesite Asphalt Co. of America). U. S. 1,683,493, Sept. 4. A mineral aggregate is mixed with a water-in-oil emulsion of a bitumen-liquefier such as heavy naphtha carrying lime, whiting or other mineral filler, and the aggregate is then coated with bitumen. Cf. C. A. 22, 2825.

Paving for tennis courts, etc. G. J. EILERS. Brit. 283,168, Jan. 6, 1927. A bottom layer of granulated blast-furnace slag carries an overlying layer of finer sifted similar slag which may be mixed with powd. red brick.

Wall-covering material formed of thin plywood veneer and paper. J. BRUNING & SOHN A.-G. Brit. 283,023, Feb. 25, 1927. Brit. 283,024 specifies thin plywood veneer coated with substances such as viscose or cellulose acetate and consolidated under the action of heat and high pressure.

Stabilized plaster composition. ALFRED H. GALLAGHER. U. S. 1,683,539, Sept. 4. A plaster of predetermined setting time is formed by adding to a gypsum plaster a nitrogenous org. retarder and a crystal-forming CaSO_4 accelerating material in suitable proportions.

Impregnating the wood of standing trees with dyes or other substances. HERBERT RENNER (to Chemicolor Wood Preserving Co.). U. S. 1,683,488, Sept. 4. Mech. features.

A. C. FIELDNER

Fuel briquets in 1927. F. G. TRYON AND J. M. CORSE. U. S. Bur. Mines, *Mineral Resources of U. S.* 1927, Pt. II, 1-8 (preprint No. 1, published July 20, 1928). E. H.

The production of domestic fuel. VII. The Turner, Hurd and coalite processes. JOHN ROBERTS. *Gas J.* 183, 310 (1928); cf. C. A. 22, 3757; VIII. **The Homite (Roberts) process.** *Ibid.* 356-7. This process is new and is capable of yielding a free-burning smokeless fuel of about 4% volatile, suitable for either domestic or metallurgical use, in standard gas-works or coke-oven equipment. It consists in passing the charge through an intermittent vertical retort or coke-oven in less than the normal coking time. Adequate heat penetration is obtained by blending the coking coal with high-volatile non-coking coal which prevents the development of the plastic layer. It is not suitable for continuous verticals because the blends must pass a $1\frac{1}{2}$ in. mesh, and static conditions are necessary to avoid the formation of a large proportion of fines in the coke. F. S. GRANGER

Influence of preheating on the theoretical flame temperature of gaseous fuels. FRITZ SCHUSTER. Berlin Municipal Gasworks. *Gas u. Wasserfach* 71, 759-61 (1928). The most practical means of attaining high flame temps. is by preheating the gas and air with waste heat rather than by the use of O. Curves and tables are given for the theoretical flame temps. of H. and CO with the theoretical amt. and 20 and 40% excess air, with both gas and air preheated to temps. ranging from room temp. to 1000°. R. W. RYAN

The AEG pulverized fuel locomotive. W. KLEINOW. *Fuel in Science & Practice* 7, 345-63 (1928).—The development of a successful powd.-coal-fired locomotive by the AEG locomotive works (Germany) is described and illustrated. After 4 yrs. of exptl. work a locomotive, fired by a low-grade coal or lignite-pulverized, has been designed that will evap. 14.4 lb. per sq. ft. of heating surface per hr., with a boiler efficiency of 67.5% compared to 52% for grate firing. Under these conditions the coal saving is 23.0%. The fuel and air mixt. blown into the firebox contains only a part of the air required for combustion. The rest is obtained by the action of the blast. Two long water-cooled burners placed opposite to each other are used and these divide the fuel mixt. into small jets. These jets are deflected through an angle of 90° and impinge against one another in the middle of the firebox with a strong circular action. The rising flame meets the preheated secondary air under the brick arch and above the ashpan; only the side walls of the firebox absorb any heat from this space. The molten slag is solidified on contact with the crown of the firebox as the heated combustion gases change direction at the end of the arch. Coal is fed from the tender by means of 2 large screws and an auxiliary screw, the latter for use with no engine load. Advantages claimed for this type of locomotive over the ordinary type are: low fuel price, independence of fuel quality, more efficient burning, higher output over a long period, shorter heating-up period, greater flexibility in control, shorter time in cleaning, very little smoke and no sparks, less manual labor for the fireman. Successful road tests have been made. D. A. REYNOLDS

simple distn. Bergius cracking executed directly on tars does not reduce the S contents of the oils. The *desulfurizing action of H and FeS₂* is appreciable only when it takes place at the moment the oils are formed, i. e., during the pyrogenic decompn. of the mols. originally present in the coal. C. C. DAVIS

A study of spontaneous combustion in storage coal. A. J. HOSKIN. *Purdue Univ. Expt. Sta., Bull.* 30, 61 pp. (1928) H. G.

The selection of a washing system for coals difficult to handle, with particular regard to the dressing of fine coal. J. HOLIK. *Montan. Rundschau* 20, 461-72 (1928). H. discusses the theory and relative advantages and disadvantages of washing coal by settling app. and by rhéolaveurs. The latter are rectilinear troughs in which the raw coal is submitted to the action of a horizontal current of water with the systematic and progressive extn. of the heavy particles deposited on the bottom of the trough. The method of arriving at a choice of a system for washing coal is illustrated by a sp. example. Conclusion. For washing fine coal the rhéolaveurs are superior to settling app. D. GORDON

A study of the action of coal on a photographic plate in the dark. G. S. HASLAM. *Sheffield Univ. Fuel in Science & Practice* 7, 253-7 (1928).—The works of previous investigators are reviewed. Expts. with both sand and powd. coal, dry and moist, show that moisture is necessary to obtain positive action upon a photographic plate in the dark. This effect is not modified by previous exposure of the coal to the sun or artificial light. "Contact" photographs are produced if blocks of coal are placed upon a film only in case O is present in the surrounding atm.; the minute detail disclosed by these photographs is due to the differences existing among the different parts of the coal in their readiness to absorb O. It is suggested that this action upon the film is due to some oxidizing compd. probably ozone, generated from the O absorbed by the coal. D. A. REYNOLDS

The use of graphical methods in the control of a coke-oven plant. G. W. J. BRADLEY. *Redbourn Works, Scunthorpe, Lives. Fuel in Science & Practice* 7, 258-67 (1928).—It is shown how graphical methods may be applied to: (a) control of a crude benzene plant, (b) cost estn., (c) calibration of storage tanks for stock-taking. D. A. REYNOLDS

Practice and progress in combustion of coal as applied to steam generation. F. H. ROSENCRANTS. *Fuel in Science & Practice* 7, 272-81 (1928). D. A. REYNOLDS

Notes on recent developments in fuel technology. R. WIGGINTON. *Fuel in Science & Practice* 7, 241-4, 287-9, 333-5 (1928).—Brief reviews on the following subjects: stability of benzene obtained from coal gas, Bergius process, steam wells of California, removal of O from feed water, water softening with Ba salts, producer gas vehicles; a rocket-propelled car, sea-temp. energy; dynamics of rockets, lignin constitution, flue dust recovery, high-pressure locomotive. D. A. REYNOLDS

Production and use of high-pressure steam by the Benson process. H. RABE. *Naturwissenschaften* 16, 565-71 (1928).—The Benson boiler, employing a water-tube system without drums, working pressure higher than the critical water pressure (225.2 atm. abs., 374°) and fed by a high-pressure pump gives off steam through a pressure-regulating throttle. An exptl. boiler built by the Siemens Schuckert works of 224 atm. (throttles to 100 atm.), 10,000 kg. steam per hr. production is described. The seamless steel tubes were of 20 by 33 mm.; the steam was used for a 1000 kw. turbo-generator. A second boiler of 30,000 kg. capacity was built for 225.2 atm. abs. or *ignore* superheated to 420° (practical limit). The steam was throttled to 180 atm., again superheated to 420° and expanded in a turbine to 35 atm., reheated to 400° and expanded to 6.5 atm., the latter being used for heating purposes. The boiler was fired with pulverized coal (air preheated to 400°); a schematic drawing is given; the turbine was geared to a 2600 kw., 6000 r. p. m. generator. For easily regulable firing like oil, pulverized coal or gas the boiler regulation can be made without accumulator; the latter, however, makes for better elasticity. The cost of a Benson installation is about the same as that of a 35 atm. boiler aggregate; the saving comes in through the heat consumption. For a Benson of 180 atm. active pressure at 440° as compared with an ordinary boiler of 25 atm. and 400° both working on vacuum of 95% the yield from 1 kg. steam in the former is 0.336 kw., in the latter 0.244 kw. Including the addnl. work of the feed pump the figures are 0.325 and 0.243. The heat requirements for 1 kw. hr. are for a Benson 2510 Cal. (efficiency 34.2%) for the 25 atm. boiler 3060 Cal. (28.1%), a saving of 22%. The absence of explosion hazards (negligible amt. of water in the boiler) is pointed out and was confirmed by practice. Bursting of a tube by stoppage merely caused a pressure drop and slight pop. B. J. C. v. d. H.

Spontaneous ignition of coal. D. J. W. KATULIN. *Brennstoff-Chem.* 8, 340-3

(1927).—Expts. are reported wherein 50 mesh coal, dried at 100°, is heated at 175° in air for 2 hrs. and then extd. for humic acids formed with 5% NaOH. Humic acids formed were higher the higher the volatile matter of the coals, except in the case of Plessey and Yard (English) coals wherein the humic acids were 168 and 58 mgs., resp. Both coals contd. 37% volatile matter. It is concluded, however, that the former coal ignites much more readily than the latter. The overall rule seems to hold that the higher the yield of humic acids from a coal, the more sensitive it is to the spontaneous ignition.

How to store coal with minimum fire hazard. J. D. DAVIS, Purdue Univ. *Power* 68, 344 (1928).—Practical suggestions are given. D. B. DILL.

Operating and test results with unusual furnace. GUY B. RAYBALL. *Power* 68, 346 (1928).—A Stirling boiler with a novel A type over feed stoker was converted into a pulverized coal plant under special conditions. D. B. DILL.

The coal dust engine. R. FAYOLLE. *Power* 68, 356 (1928).—An illustrated description of an engine in use in Germany, Germany, and 1910. It has been operated with nearly all grades of German anthracite and bituminous coals, and has been operated with flour and coke. It develops 110 brake hp. Fuel and combustion air are compressed simultaneously but kept separate until combustion occurs. D. B. DILL.

Efficiency of 89 percent with Calumet powdered coal burner. A. D. BATTERY AND W. H. JENSEN. *Power* 68, 224 (1928).—The installation has 5940 sq. ft. of surface and has double the capacity of a 15,000 sq. ft. stoker fired boiler in the same plant. The former occupies 50% more space and has 50% the furnace maintenance cost. Of the ash passing to the stack, 90% is eliminated by a gas washer. D. B. DILL.

Burning oat hulls and refuse in powdered coal furnaces. C. J. HERBECK. *Power* 68, 312 (1928).—An illustrated account. D. B. DILL.

Closing mechanism for the charging hopper of central producers. J. BUTIS. *Helv. Gas* 48, 331 (1928).—An annular watersal with vent is advocated. B. J. C. VAN DER HOEVEN.

Motor gasoline substitute from domestic raw materials. FRIGYES KONK. *Matematik. Természettudományi Értesítő* 41, 9 (1928).—By a contact dehydration process K. has produced a mixt. of isomeric hydrocarbons from fuel oil A 20:40 mixt. of these hydrocarbons with C_2H_6 and CH_3OH is a satisfactory motor fuel. The C_2H_6 does not freeze out at -10° to -15° . The mixt. has a low flash point. J. S. RECHER.

Uniform composition of manufactured gas. C. I. PHILIPS. *Helv. Gas* 48, 238 (1928).—For const. delivery of equal amts. of heat from gas fired app. the Bunte factor (caloric value) $\times d$, has to be kept const. This could easily be accomplished by using a (Junkers type) recording calorimeter, run on gas of const. pressure (not quantity) and const. water flow. For const. caloric value deficiencies in the quotient can be made up by varying the gas pressure proportionally with d . A pressure regulator of the Bamag-Dalem type would with certain changes suit this purpose. The lower caloric value has to be considered for this purpose. B. J. C. VAN DER HOEVEN.

Gas calorimetry. J. S. G. THOMAS. *Chemistry and Industry* 47, 829 (1928).—The basis of all charges for gas in England is the product of the total vol. of gas supplied and the declared caloric value of the gas. This caloric value is defined as the B.t.u. produced by the combustion of 1 cu. ft. of gas measured at 60° F. and 30 in. of Hg and satd. with water vapor. Penalties are inflicted if, for any consecutive 2 hrs., the caloric value is more than 6% below the declared value or if, in any quarter, the av. caloric value is less than the declared value. The gas referees of England are required to prescribe, in any necessary case, a calorimeter which will give a continuous record of the caloric value of the gas supplied. Up to the present time, they have not prescribed any form of recording gas calorimeter but have advocated "snap-testing" of the gas supply, supplemented in isolated cases by a recording calorimeter. In any successful recording calorimeter, the following variables—temp., pressure and sp. gr. of the gas supply, the temp. and infallibility of positive water flow, etc., are difficulties which must be overcome. Much success in overcoming these difficulties is met in at least 4 commercially available forms of gas calorimeters: (1) Simmance, in which it is attempted to maintain the rates of flow of the water and gas const.; (2) Fairweather, in which no attempt is actually made to correct the gas rate for varying temps. and pressures; (3) Boys, in which the gas and water flow at fixed and unalterable rates; and (4) Thomas, in which air instead of water is used as the calorimetric fluid. The Fuel Research Board reports that the Thomas type of calorimeter will record the

calorific value of a gas (of steady calorific value of 500-600 B.t.u.) correct to ± 1 B.t.u. T. recommends that all such types of calorimeter be tested for the completeness of combustion of the gas in the calorimeter. None of the recorders or indicators at present used with the above 4 calorimeters is exactly what is necessary. J. H. P.

Dry coal gas purification. J. W. MEUSER. *Het Gas* 48, 233-51 (1928).—An extensive review of chemistry (H_2S and CN absorption, regeneration, CNS formation, etc.) and practice (air or steam addn., switching systems, gasflow in boxes) of the dry purification process. The use of active C for formation of free S is also discussed. Forty references are given.

B. J. C. VAN DER HOEVEN

Dehydration of gas. J. C. MEUWISSEN. *Het Gas* 48, 291-5 (1928).—A review of different processes for dehydration of gas with cost data. For the compression method the cost is from 20¢ to \$1.60 per 1000 cu. m., for dehydration with H_2SO_4 from 34 to 18¢, with $CaCl_2$ 16.4¢ (Taunton) or 8.0¢ (Portsmouth), with glycerol 11.2¢ (Nottingham). No data for cooling or silica gel dehydration are available.

B. J. C. V. D. H.

Equilibrium conditions in the formation of hydrocarbons and alcohols from water gas. H. TROPSCH. *Brennstoff-Chem.* 8, 376 (1927).—Smith states (*C. A.* 21, 2783) that equil. calcs. show that, as the temp. is increased, formation of higher rather than lower hydrocarbons is favored, whereas exptl. work of T. shows that high temps. favor formation of CH_4 . Smith also finds that increased pressure favors production of higher paraffins. This agrees with exptl. results of T. except that oxygenated compds. are formed at temps. high enough to drive from the catalyst the higher hydrocarbons which have been formed.

J. D. DAVIS

Alternative methods of blue gas enrichment. R. V. KLEINSCHMIDT. Arthur D. Little, Inc., Cambridge, Mass. *Ind. Eng. Chem.* 20, 909-12 (1928).—Three-fourths of the gas oil employed for enrichment of water gas in this country is used on the north Atlantic seacoast, it must be possible to deliver a competing material in New York and surrounding markets. Coal gas can be so used, especially if there be a plant of considerable magnitude close to a market which can absorb coke, tar and NH_3 as required. Natural gas is available in enormous quantities in certain parts of the country and better pipe line facilities will spread its use to other sections, but on the whole its sources are too far from the main markets to make it important as a competitor of gas oil. Refinery gases, on the contrary, are often available in the gas oil consuming territories, and may be looked upon as logical substitutes for oil in blue gas enrichment. Refineries located in the oil fields can produce C_2H_4 and C_3H_8 by stripping methods and ship these in liquid form to more distant gas plants. The availability of catalytic condensation processes depends upon their commercial development, and will be stimulated by a pronounced rise in the cost of hydrocarbons. Equipment required for the utilization of the enriching materials considered is of great simplicity. Another advantage of all the new methods noted, as compared with gas oil, is that the enriching material may be freed from S before being mixed with water gas, thereby increasing the efficiency of purification. The advantages of using gaseous hydrocarbons are so great one ought to consider the possibility of operating a small oil refinery primarily for the purpose of producing enrichment gases, the secondary products being motor fuel and tars. Tables and a series of curves give the relative values of enriching materials under assumed conditions. Proper cooperation between oil refineries and gas works would be of benefit both to the oil refineries and to the gas works. W. C. E.

Inflammability of automobile exhaust gas. G. W. JONES. Pittsburgh Expt. Sta., U. S. Bur. of Mines. *Ind. Eng. Chem.* 20, 901-3 (1928).—Applying the law of mixts. to the inflammability of gases, with a generalized form of LeChatelier's equation, viz.,

$$L = \frac{100}{(P_1/N_1) + (P_2/N_2) + (P_3/N_3) \dots}$$

in which P_1 , P_2 and P_3 are the percentages of each combustible gas present in the original mixt. (free from air and inert gases), so that $P_1 + P_2 + P_3 \dots = 100$, and N_1 , N_2 and N_3 are the limits for air in each combustible gas separately, it has been found that results have checked fairly closely, when a large number of mixts. contg. various proportions of H , CO , CH_4 , N and CO_2 have been prep'd., and then the limits of inflammability calcd. and detd. experimentally. Similarly mixts. representing mine-fire gases, detonation gas from explosives, gases after mine explosions, and blast furnace gases have been tested. Calcd. values may vary from the actual limits by 0 to 2.5%. Tables and graphs giving necessary data on compn. and inflammability of gas mixts., with illustrations of their use, are presented. In view of the fact that automobile exhaust gases have inflammable limits under certain

conditions, care should be taken when using these gases for killing animals or for other similar purposes; otherwise accidents may result from the presence of sparks, arcs or flames.

The influence of external heating on the rate of flame propagation in gases. K. BUNTE AND A. STEDING. *Gas Inst. Gas u. Wasserfach* **71**, 673-7, 701-5, 731-4 (1928).—Measurements of the rate of flame propagation for H_2 , CO , CH_4 and mixed gases were made by the method of Ubbelohde and de Castro (*C. A.* **5**, 3726) in which the height of the inner cone of a Bunsen burner was measured and the area of the cone computed. The rate of flame propagation is then equal to the rate at which the gas and air reach the surface of the inner cone. A special burner was constructed, cooled to eliminate preheating of the gas or air and this was inserted into an elec. furnace. Gas and air rates were measured by capillary flow-meters. A trace of CS_2 was added to pure H_2 so as to make the inner cone of the flame visible and the effect of this on the rate of flame propagation was found to be negligible. CO and CH_4 were purified to remove H and heavier hydrocarbons. The rate of flame propagation was detd. for mixts. of the various gases with air at temps. from 20° to 1000° , and these data are given in tables and curves. External heating had a comparatively large effect on the rate of flame propagation in H -air mixts., but little with CO and methane showed a slight decrease on heating. Water gas contg. about 50% H_2 showed a marked increase in rate of flame propagation on heating but the addn. of H_2 to coal gas to a total content of 36 to 40% H_2 influenced the rate only slightly. The large effect with H is probably due to its high thermal cond. as compared to that of the other gases. R. W. R.

Corrosion in gas technic. C. G. DRIESSEN. *Het Gas* **48**, 271-80 (1928).—A review of corrosion theories. It is concluded that dehydration of gas will completely prevent corrosion; and decrease of O_2 and CO_2 of the gas will materially help to reduce corrosion. A table is given of the soly. of O_2 in distd. water and in gas main condensate from 0° to 100° . In mg. per l. it runs from 14.56 and 14.10 at 0° to 5.47 and 5.31 at 50° , zero at 100° . Salt concn. of the condensate has an increasing corrosive effect with a max.; NH_4Cl , $(NH_4)_2SO_4$ and $FeSO_4$ all present in the condensate are strongly corrosive. The max. attack is shown by an approx. normal soln. By coating expts. with agar- $K_3Fe(CN)_6$ -phenolphthalein (ferroxy reagent) the presence of local elements on Fe surfaces can be shown by blue or red coloration. The occurrence of this important factor for the corrosion was found in decreasing order on cast iron, wrought iron, steel, stainless steel, Monel metal, the last one being altogether free. It is suggested that the ferroxy reaction be used for regular testing of material. Numerous references are given. B. J. C. VAN DER HOEVEN

Gas regulators and safety appliances. SCHUMACHER. *Gas u. Wasserfach* **71**, 697-701 (1928).—A discussion, with illustrations, of modern European and American gas regulators and safety features of various gas-using equipment. Also in *Z. osterr. Ver. Gas Wasserfach* **68**, 159-67 (1928). R. W. RYAN

Examination of benzene wash oils. J. C. MEUWISSEN AND D. THOENES. *Het Gas* **48**, 260-9 (1928).—Four liquids were examd. for their qualities as benzene wash oil: fresh wash oil (d. 0.982, 90.4% between 200° and 300°), used wash oil, coal-tar distillate and tetralin. The washing power was detd. according to Petit (*C. A.* **20**, 981) by burning a known amt. of air, satd. with benzene vapor over the satd. wash oil, in a Drehschmidt capillary and detg. the vol. contraction of the combustion products collected over KOH . Every percent benzene in the air gives a $8\frac{1}{2}\%$ contraction. A second method, employing wash bottles with benzene and wash oil in series and detn. of benzene absorbed by weight, was found less satisfactory. The Petit method gave a vol. contraction proportional to the benzene content of the wash oil for benzene concns. up to 8%. From tabulated data of benzene nos. (contractions observed corrected to 15° and calcd. for 3% benzene in the wash oil) great similarity appears between the absorption qualities of the coal-tar fraction between 200° and 300° and the fresh wash oil, indicating the probable suitability of the former (gas-works product). Also redistd. wash oil appears quite suitable. The highest-boiling coal-tar fractions are best; tetralin is good and paraffin oil is inferior. B. J. C. VAN DER HOEVEN

Low-temperature tar oil as a Diesel engine fuel. YOSHISADA BAN AND TETSURO SUWA. *The Imperial Fuel Research Institute, Japan. J. Fuel Soc. (Japan)* **7**, 598-606 (In English 57-60) (1928).—The authors have examd. several low-temp. tar oils produced at the Institute as a fuel for 33 b. h. p. Diesel engine, that is, a single-cylinder four-cycle vertical type Niigata engine, with cylinder dimensions 280 X 416 mm., and had a rating of 33 b. h. p., at 230 r. p. m. The results of the test are illustrated by means of a graph, and it is shown that such oil like pitch and acid-free oil can fulfil any Diesel oil specification. The test was also made to ascertain how low-

temp. tar should be treated to prep. it as a Diesel oil. The results are illustrated and the authors claim that low temp. tar should be freed both from tar acids and solid paraffin. The chem. and phys. properties of these oils, crude tars and Diesel oil used in the test are tabulated.

F. I. NAKAMURA

Hydrogenation of neutral oil of low-temperature tar. SABURO TASHIRO. The Imperial Fuel Research Inst., Japan. *J. Fuel Soc. (Japan)* 7, 626-35 (In English 67-70) (1928).—The sample used was the middle fraction of neutral oil of low-temp. tar from Fushun coals, and had the following properties. $d_{20} = 0.9245$, $n_D^{20} = 1.2240$, and I value = (Hubble) 60.9. A 250-atm. autoclave of 600-cc. capacity was suspended horizontally, heated with an elec. heater fitted around the autoclave, and shaken horizontally. One hundred cc. of oil was taken and H was pressed into the autoclave at the proper pressure. After the current was passed on, shaking of the autoclave began. When the temp. reached a definite point, it was kept there for a definite period and then cooled. The temp. and pressure were recorded every 2 min., in order to exam. the nature of the reaction, and 3 curves were obtained, namely, temp.-pressure, temp.-time and pressure-time. The effect of pressure, effect of temp. and effect of catalyzer are discussed and the results are tabulated. Summary: The neutral oil of low-temp. tar can be hydrogenated by direct hydrogenation with H₂ under high temp. and pressure, but cannot be satd. completely. The hydrogenation reaction is the most active just below the reaction temp., and above that decompn. takes place. Seventy-five atm. of the initial pressure is the lowest limit for hydrogenation, and an increase of the initial pressure makes the hydrogenation profitable. Hydrogenation proceeds below the reaction temp., while above that decompn. takes place. NiO has a remarkable effect in aiding hydrogenation, and if added sufficiently, the oil can be satd. Fe₂O₃ is weaker than that of NiO. CuO and MgO have little effect. ZnO has an effect in decreasing the I value without changing other properties. Al₂O₃ seems to give no effect but rather accelerates decompn.

A modern coke-oven plant. ANON. *Engineer* 146, 169-72, 191-5 (1928). The plant of the South Yorkshire Chem. Works, Ltd., Parkgate, near Rotherham is described with layout, flow-sheet and illustrations. The plant is largely modeled on American practice.

D. B. DILL

Spent gas liquor in relation to sewage disposal (HOOPER) 14. Internal corrosion of fuel economizers (INGHAM) 14. Grinding and separating apparatus for coal (Fr. pat. 635,083) 1.

LOUIS, HENRY: **The Preparation of Coal for the Market.** London: Methuen & Co., Ltd. 217 pp. Cloth, 10s. 6d. Reviewed in *Mining and Met.* 9, 421 (1928); *Chemistry & Industry* 47, 778.

Fuel. HERBERT E. WETHERBEE (one-third each to Richard F. Grant and Howard M. Hanna). U. S. 1,683,061, Sept. 4. A mass of moistened small anthracite or like material is treated with a suitable filming oil to displace the water and drying is then effected to insure adherent action of the oil.

Preparing fuel containing moisture and hydrocarbons. HENRY F. MAUREL. U. S. 1,682,680, Aug. 28. In treating fuel such as low-grade de-ashed hard coal for baking and hardening it, oil vapor and steam produced from the fuel are driven, together with air or O₂, under the fuel and through the body of the latter and over means for heating the vapors to render them suitable for treating the solid fuel. An app. is described.

Fuel for internal-combustion engines. EARL C. HENNEN (to United States Nitro Co.). U. S. 1,682,561, Aug. 28. A hydrocarbon fuel such as gasoline 500 gal. is mixed with a high heat test lubricating oil 34 oz., castor oil 17 oz., C₂H₆ 65 oz. and p-nitrochlorobenzene 12 oz.

Fuel briquets. GEORGE F. SHERHAN. U. S. 1,682,195, Aug. 28. Briquets are formed of coal 90, crude oil 2, S 2 and a suitable binder such as asphalt, tar, pitch or gilsonite 6%.

Briquetting fuels. E. W. BOWEN. Brit. 282,800, Sept. 30, 1926. See U. S. 1,667,304 (C. A. 22, 2048).

Briquetting fuel with molasses as a binder. PAUL C. MULLIGAN (in part to Luther J. Hull and Isaac M. Foster). U. S. 1,683,094, Sept. 1. After heating the base material such as coal and wood charcoal it is mixed with molasses and heating of the mixt is continued to drive off water contained in the molasses but at a temp. below that which would drive off volatiles from the fuel. The mixt. is then cooled to a briquetting consistency, pressed and baked to carbonize the binder. An app. is described.

Apparatus for drying and baking briquets. L. NYAET. Brit. 283,123, Jan. 3, 1927.

Distilling fuel in a rotating drum or retort. E. POSER. Brit. 283,420, June 20, 1927. Fuel is distd. in chambers in a rotating drum or retort, and is compressed after it softens during distn. by a plunger which enters each chamber in turn during a period of rest of the drum. Various details of construction of the app. are specified.

Low-temperature distillation of carbonizable solid fuels. EDMOND G. WEEKS (one-half to Merz & McLeelland). U. S. 1,683,450, Aug. 21. In order to effect low-temp. distn. of solid fuels such as coal for recovery of highly volatile oils and partial carbonization of the remaining fuel without gumming, the material is partially carbonized by passing steam and atm. air in regulated quantities to an enclosed body of the fuel, one of these components being preheated to a temp. such that the temp. of the mixt. of steam and air while being mixed is at least as high as the temp. of ignition of the fuel, so that a portion of the fuel is ignited, the quantity of atm. air admitted is limited to that necessary for combustion of a small proportion only of the fuel. An app. is described.

Distilling coal and similar materials. CARLSHUTTE A.-G. IUR. EISENGIESSEREI UND MASCHINENBAU. Brit. 283,250, Oct. 2, 1926. In drying and distg. coal and cooling the coke residue, an app. is used (which is described) in which gases are passed transversely through the material in a cyclic manner, the heating gases are reheated before each passage through the charge.

Hydrogenation of coal. A. UHLMANN. Brit. 283,177, Jan. 6, 1927. Hydrocarbons are obtained by passing a pulp composed of fine coal and water through a high-frequency field. Ice may be mixed with the water or the app. may be surrounded with a refrigerant. H may be supplied but is not required as the H may be derived from the H_2O . An app. is described.

Destructive hydrogenation. I. G. FARBENIND. A.-G. Brit. 282,814, Aug. 14, 1925. The process described in Brit. 256,964 (Cl. A. 21, 3122) is applied to the destructive hydrogenation of liquid carbonaceous materials such as oils, tars, resins, asphalts and their conversion products. Brown coal producer tar contg. 30% by wt. of crude brown coal may be fed continuously into a high-pressure vessel coated with Mn bronze and treated with H under a pressure of 200 atm. at 450°. The products are cooled by heat interchange with the H and a thin liquid product contg. 25% of "benzines" is produced. Before being cooled, the products also may be passed through a second vessel contg. a catalyst such as Mo. Cl. A. 22, 3763.

Transformation of coal, tars, mineral oils, etc. I. G. FARBENIND. A.-G. Fr. 634,822, May 21, 1927. In the manuf. of hydrocarbons of low b. p. from coal, etc., the starting materials are first treated with disintegration catalysts and then with hydrogenation catalysts. As disintegration catalysts, elements of the 3rd and 4th groups of the periodic system, mixts. of Cu and Fe, activated C, active SiO_2 , hydrosilicates and Al_2O_3 are mentioned, and as hydrogenation catalysts, Mo, W or their compds.

Transformation of coal, tars, mineral oils, etc. I. G. FARBENIND. A.-G. Fr. 634,821, May 21, 1927. In the transformation of coal, etc., into hydrocarbons of low b. p. with H or gases yielding it, the gases remaining after condensation of the liquid products are washed with benzine or the low-boiling hydrocarbons obtained in the process itself, to remove gaseous hydrocarbons.

Transformation of coal, tars and mineral oils into products of greater value. I. G. FARBENIND. A.-G. Fr. 634,820, May 21, 1927. Hydrocarbons of low b. p. are obtained by submitting suspensions of coal, tars, mineral oils or their distn. products, being, for the main part, in the liquid state, to a heat treatment under pressure in the presence of catalysts, and leading the products formed, in the state of vapor and preferably superheated, over catalysts. This procedure allows a lower temp. to be used for the first operation. Indifferent gases or gases taking part in the reaction or their mixts. may be added, such as H, steam, CO_2 , CO, N or gases such as NH_3 , which have a catalytic action.

Oils and coke from coal, etc. H. NOVAK and A. BROD. Brit. 283,269, Oct. 5, 1928. Coal, brown coal or the like is heated in admixt. with an aromatic hydrocarbon liquid b. above 230° (suitably 1,6 dimethylnaphthalene or other alkyl naphthalene,

anthracene oil or liquid fractions of coal tar) under 25-30 atm. pressure in an autoclave connected with a reflux pipe and a condenser. The temp. is gradually raised to 500°. Benzine distils over followed by the aromatic liquid which is used again. The residue is subjected to dry distn. and yields a distillate of tar rich in aliphatic compds. and a residue of semi-coke.

Separating coal from other materials by use of a calcium chloride solution or similar agent for gravity separation. R. LESSING. Brit. 282,874, Sept. 27, 1926. An app. is described.

Retort and pipe system, etc., for distilling coal and tar. S. P. MÜLLER (to Barrett Co.). Brit. 282,826, Dec. 31, 1926.

Retort furnace adapted for carbonizing coal. CHARLES V. MCINTIRE (to Consolidation Coal Products Co.). U. S. 1,681,946, Aug. 28. A horizontally disposed retort comprises a bottom part of fire brick or other suitable refractory material having a trough-shaped upper surface with transverse grooves formed therein and a metallic lining of inverted trough-shaped sections in and over the grooves so as to form a passage or flue for heating gases.

Furnaces using powdered fuel. JAMES JOHN CANTLEY BRAND and BRYAN LAING. Fr. 634,916, May 24, 1927. To facilitate the flow of powd. carbonaceous material to furnaces, air or flue gas is forced into the material. A powd. coke is the preferred form of fuel used.

Charging and discharging gas retorts, etc. C. EITLE, MASCHINENFABRIK. Fr. 634,855, May 23, 1927. The ejector for gas retorts or horizontal or inclined distn. chambers is hollow and forms the mouthpiece of the charging app., which may be a centrifuge.

Gas burner. SAMUEL E. DIESCHER. U. S. 1,683,128, Sept. 4.

Gas holder. JOHN H. WIGGINS. U. S. 1,683,005, Sept. 4. Structural features.

Apparatus for washing producer gas. E. WARNANT. Brit. 282,851, Sept. 2, 1926. Gas is passed through columns filled with coke or metal turnings and treated with water. The device is suitable for use on motor vehicles.

Water gas. CLAUDE W. BOTSFORD (to William W. Odell). U. S. 1,682,264, Aug. 28. In making water gas from solid fuel in a single generator, an ignited fuel bed is first air-blasted alternately up and down from about midway the ends of the bed; the air blast is then shut off and a straight up-stream run is made with introduction of steam from beneath the fuel bed, the finished gas is removed from above the fuel bed. An app. is described.

Combined water-gas generator and gas producer. CLAUDE W. BOTSFORD (to Wm. W. Odell). U. S. 1,683,155, Sept. 4.

Oil-spray purge mechanism for water-gas apparatus. FRED B. HAYES (to Western Gas Construction Co.). U. S. 1,682,277, Aug. 28.

Apparatus for feeding coke to water-gas generators, etc. POWERGAS CORP., LTD., AND N. E. RAMBUSH. Brit. 283,238, Aug. 4, 1926.

Apparatus for quenching and conveying hot coke. SOUTH METROPOLITAN GAS CO. AND C. H. SMITH. Brit. 282,861, Sept. 24, 1926.

Tapering vertical coke-oven construction. J. VAN ACKEREN (to Koppers Co.). Brit. 283,191, Jan. 8, 1927.

Hydrogen from coke furnaces. RUDOLF BATTIG. Fr. 634,711, May 19, 1927. The gases from coking coal or other carboniferous materials are fractionated, and the CH_4 fraction is passed through coke at a temp. of about 1000° to produce fresh quantities of H_2 ; the coking furnace itself may be used for this purpose.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

F. M. ROGERS

The petroleum industry in America. BENJAMIN T. BROOKS. *J. Soc. Chem. Ind.* 47, 225-30T(1928). E. H.

Technical problems and advances in the petroleum industry. J. C. MORRELL. *J. Western Soc. Eng.* 33, 335-46(1928). E. H.

The modern petroleum synthesis. EDUARDO VITORIA. *Mem. acad. cienc. arts Barcelona* 20, 439-57(1927).—Cu as cuttings and as powder, and a Ni catalyst were used. For raw material the fraction of vaseline and paraffin oil was used which passed between 221° and 261° at 76 mm. pressure, $d_{44} = 0.870$; $n_D = 1.4698$. Heating this oil

for 2-5½ hrs. at 280-290° produced 2 new fractions, a higher and a lower one, the latter distg. between 172 and 221°, at about 67 mm. pressure, representing 61-80.6% of the original material, $d_{40} = 0.858-0.8700$. Passing acetylene does not have any pronounced effect. The catalyst showed no signs of poisoning on repeated use. The authors believe that this improved method of low-temp. cracking might find industrial application in the future.

Alumina gel as a desulfurizing agent in petroleum refining. R. D. BUMBACHER AND R. C. BAGCHI. *J. Indian Chem. Soc.* 5, 111-25 (1928).— Al_2O_3 gel (water content 6%), activated under optimum conditions by the ignition of $Al(OH)_3$ at 350-400°, absorbs a large number of S compds. form their solns. in petroleum, and more especially those in which the S is contained in an oxidized form. Thus a preliminary oxidation of solns. of bivalent S compds. by the passage of air in the presence of Al_2O_3 gel leads to more complete adsorption (cf. G. P. 405,850). Adsorption is also increased by the use of large amts. of very finely divided Al_2O_3 gel, but these modifications involve loss of petroleum and difficulties of filtration. Admixture of activated C with the gel yields an adsorbent which is more efficient than either of its components. More pronounced results are obtained by the use of a mixt. of Al_2O_3 and silica gels, prepd. by the pptn. of Al_2O_3 gel on silica gel followed by ignition at 230-235°. No increase in activity is obtained by the pptn. of the Al_2O_3 on an inert surface such as powdered glass or pumice. Al_2O_3 gel may be reactivated by treatment with superheated steam and air. The application of Freundlich's equation in the examples in which the pure gel is used show that the action is one of true adsorption.

Determination of halogens in water from petroleum beds. P. PETRESCU. *Bucarest Geol. Inst. Bul. soc. chim. Roumanie* 10, 26-8 (1928).—Detn. of I is difficult as it is reabsorbed as soon as liberated because of org. matter. A satisfactory method is based on this reaction: $H_2O_2 + 2HI \rightarrow I_2 + 2H_2O$. The sample is acidified with 0.5 cc. dil. HCl and treated with 1 to 3 drops of perhydrol or 1.5 cc. of H_2O_2 . Agitate strongly with CS_2 several times during 30 min. and titrate with $Na_2S_2O_3$. Concording figures are obtained even 48 hrs. after liberation of I. Br is not liberated by this method.

Notes on tar from Russian oil shale. G. I. STADNIKOV AND A. E. WEIZMANN. *Brennstoff-Chem.* 8, 343-5 (1927).—A Kaschper (Volga) oil shale contg. 3.8% S is distd. in a Fischer rotary rectort both with and without circulation of CO_2 during distn. The yields of tar were 11.1 and 15.0%, resp. The light oils were treated with Petrov's reagent (CH_2O and naphthasulfonic acid) to remove acidic S compds. After distg. the remaining oil with steam, washing with dil. H_2SO_4 and NaOH and boiling over metallic Na, the fractions, b. 105-220°, were investigated for thiophene and its derivs. Analyses of derivs. formed by acetylation in the presence of $SnCl_4$ indicated the presence of ethylthiophene and propylthiophene or one of its isomerides. J. D. DAVIS.

Crude oil in Kamchatka (Bogachevskii district). S. S. NAMETKIN. *Moscow. Neftyanoye Khozyaistvo* 14, 650-1 (1928).—Sample of oil taken from the right bank of the river Bogachevka gave the following analysis: sp. gr. at 15° 0.849, viscosity Engler, 1.17, flash (Abel-Penskii) 32.5°, excise resins 1.2%, S 0.05%. It represents a high-grade kerosene and gasoline crude oil.

Distillation in a flow of nitrogen gas. A. ZAKHARENKO. *Azerbejdj. Neftyanoye Khoz.* 1928, No. 6-7, 68-72.—A mazout from Baku crude which had the following characteristics was distd. in a flow of N, sp. gr. 0.9119, viscosity E_{60} 6.5, flash (Martens-Penskii) 127°, flash (Brenken) 147°, cold test below -17°, excise resins 22%. Air was entirely excluded during the distn. and the N was recirculated through the system. Four fractions were sepd., the residue being 34%. The third fraction (40-60%) was of a superior color after acid and caustic treatment, the color scale compared 26 mm. against 15 mm. for steam-distd. oil. The acidity was also lower and compared 0.040% against 0.11%. No difference could be observed in other qualities.

"Voltol" oils, their preparation and uses. HORST BRÜCKNER. *Chem.-Ztg.* 52, 637-8 (1928).—Technically the "Voltol-izing" of an oil is effected by exposing it to a discharge of 4500-4600 volts, single phase, 470-480 cycle current, in an atm. of H_2 at reduced pressure, and at a temp. of 60-80°, the temp. being maintained from the discharge itself. Similar reactions are effected with oils of mineral, vegetable and animal origins. The lubricant formed is well adapted to Diesel engines, airplanes and automobiles as it retains its viscosity at high temps. For lubricating greases it forms a permanent emulsion. The detn. of viscosity by the viscometer of Ubbelohde, Duffing and Vogel is recommended, rather than the usual Engler test. W. C. EBAUGH.

Maikop oils. A. N. SAKHIANOV AND M. A. BESRUZHEV. *Neftyanoye Khozyaistvo* 12, 402-6 (1927).—Four crude oils from the Maikop district are described. They are

entirely different from other Maikop oils. (1) *The heavy crude oil from Shirvanui*: sp. gr. 0.935, E_{20} 6, cold test below -18° , paraffin wax 0.31%, excise resins 25%, neutral resins extd. with silica gel 10.7%, asphaltenes 0.84%, sp. gr. of asphaltenes 1.12, sp. gr. of resins 1.05, S 0.30%, gasoline 0%, kerosene (200-270°) 10%. Mazout: sp. gr. 0.945-0.949, E_{20} 12 $\frac{1}{2}$, flash (Brenken) 158°, cold test below -18° . (2) *Light crude oil from Shirvanui*: sp. gr. 0.830, cold test below -20° , excise resins 12-14%, asphaltenes 0.33%, silica-gel-extd. resins 6.51%, gasoline 24%, sp. gr. 0.728, kerosene 13.3%, sp. gr. 0.837, flash 62°, acidity 0.020% = 2% of naphthenic acids. Mazout: sp. gr. 0.930, E_{20} 6-7, low cold test (cf. Kosior, *Neftyanoe Khozyaistvo* 1926, 10). (3) *Crude oil from the upper horizon of Khaduizhinskii*: mixed paraffin and asphalt base crude, similar to Shirvanui crude (light) but higher in paraffin content, sp. gr. 0.871, cold test -20° , paraffin wax 1.46% (m. 50-52°), excise resins 18%. (4) *Crude oil from the lower horizon of Khaduizhinskii*: sp. gr. 0.850, cold test 0° to -7° , paraffin base oils, paraffin wax 4.5% (m. 49-52°), excise resins 16%, neutral resins extd. by silica gel 7.1% (sp. gr. 1.025); mazout: sp. gr. 0.906, E_{20} 4.02, cold test plus 21° , excise resins 24.5%, flash 150°. Complete distus. were made of crudes and mazouts (under vacuum). Conclusion: Shirvanui crudes are characterized by their gasoline and kerosene, also by high sp. gr., which comes close to Kaluga crude. The machine oil distillates of both crudes have a sp. gr. of 0.945, the spindle oil 0.930. The Kaluga oil having a higher sp. gr. is higher in asphaltenes and resins and lower in kerosene fractions. The light crudes from Shirvanui and Khaduizhinskii differ in paraffin contents 1% and 4 $\frac{1}{2}$ %. The low horizon Khaduizhinskii crude has the highest % of wax and is low in sp. gr.

A. A. BOEHLINGK

Molecular weights and boiling points of mineral oils. A. N. SAKHANOV AND N. A. VASIL'EV. *Groznyi Neftyanoe Khozyaistvo* 14, 643-50(1928).—The following crude oils were investigated: Grozny paraffin base, Balakhanuii, Grozny non-paraffin base, Binagadii and Kirmaki. The Gliniskii type dephlegmator was used. Fractions up to 300° were distd. under atm. pressure; vacuum was used for higher fractions. Oil fractions within the same limits of temp. have approx. the same mol. wt. Mol. wts. of oil fractions of the same viscosity depend on the nature of the oil; they are highest for paraffin-base oils, intermediate for naphthenic-base oils of the Balakhanuii type, and lowest for asphalt-base oils. The distn. or boiling temp. of fractions which are the same technically varies with diff. oils. Mazouts from diff. oils give the following fractions of cylinder stock: Grozny, paraffin-base 9%, Balakhanuii 14%, Grozny non-paraffin-base 30%, Binagadii 27% and Kirmaki 33%. High vacuum is not required for the distn. of lubricating oils from paraffin-base crude oil.

A. A. BOEHLINGK

The dielectric losses of transformer oils. I. L. S. ORNSTEIN, G. J. D. J. WILLEMSE AND J. H. G. MULDER. *Univ. Utrecht. Z. tech. Physik* 9, 241-6(1928).—The losses were measured (cf. *Elektrotechnik*, Jan., 1928) directly by thermal effect in order to be independent of frequency. The temp. rise of the oil was found thermoelectrically. the exptl. condenser was well insulated for heat; and the frequencies used were between 0 and 500. The heat losses were detd. from a cooling curve for zero current, the temp. changes being of the order 0.001° to 0.01°. The condenser-calorimeter was standardized with d. c. No considerable dependence of dielec. loss on frequency was found; from this and from addnl. cond. measurements it was apparent that the losses are quantitatively explainable by conduction. For every potential applied the latter has a value dropping with time to a min. (after about 60 min.), which increases with increasing potential. It is assumed that this conduction is electrolytical and consists of a variable (proportional to ion concn.) and a const. part: $S = \sigma_0 + bc$ or $S = \sigma_0 + Ae^{-abE}$, where E is potential difference. For 10 out of 14 oils examd. this relation represents the data exactly. Thoroughly dried oil did not show the time effect, neither did pure synthetic hexane; 24-hr. standing of the oil or stirring promoted the conduction. By continued electrolysis of the oils the oil can be stabilized, i. e., the cond. drops to the const. value. Amts. of stabilized transformer oil were prepd., of which S was lowered from $0.4 \cdot 10^{-8}$ amps. per sq. cm. for 17.5 kv. per cm. to $0.2 \cdot 10^{-8}$ amps. per sq. cm. by application of 16 and 45 kv. per cm. fields for 5 hrs.; the breakdown potential rose from 20 to 50 kv. per cm. The stabilized oil showed a frequency effect in the losses. Part of this and an irregular rise of loss with potential gradient were found due to ionization of air dissolved in the oil (controlled by heating of oil and subsequent aeration with P_2O_5 -dried air). A cable oil of breakdown value 84 kv. per cm. improved to 125 and showed no measurable conduction (less than 10^{-10} amps. per sq. cm.) at 63 kv. per cm. after heating at 130° for several hrs. and cooling *in vacuo*. Other heated oils had losses independent of potential and increased slightly with frequency. The $\log \sigma = \log A + bE$ curves at different temps.

approach straight lines more and more for high temp. (140°). The product $\sigma\eta$ (η is viscosity) is practically const. with varying temp. The $\log \sigma$ $\log \eta$ lines show, however, a bend at 40°, probably due to melting of solid matter (paraffin).

Determination of unsaturates in lubricating oils. FREDERICK S. BACON, A. I., Little, Inc. *Ind. Eng. Chem.* 20, 979 (1928). The Fehling's method has been modified to give a satisfactory end point on dark colored materials. Twenty-five cc. of 10% H₂SO₄ are mixed in a 200 cc. separator funnel with from 1 to 10 cc. of the oil to be tested, diluted with at least 10 cc. of CCl₄. A 10% soln. of known unsatd. content soln. of KBr and KBrO₃ is added with stirring until the color of the oil layer shows an excess of Br. KI soln. is then added, and the color of the oil layer shows an until 1 and 2 cc. excess of the latter is added. The oil is then titrated back with Na₂S₂O₃ soln. oil washed with water and the aq. layer and water are titrated with standard I soln.

Crozier carbonizing retort. A. S. CROZIER, *Ind. Eng. Chem.* 20, 823 (1928). A retort said to be successful with Burmes coal in which Scotch splint had been used and which is expected to be satisfactory for coal which does not unduly cake. It is of cast iron, built up of units, has a riveted wall 15 ft. high, 15 in. apart with semicircular ends, setting leaves space for heating gases around the retort. The charge is fed in at the top through 2 hoppers and is to be cooled by a rotating helix into a coke chamber and thence through a water seal. Working temp. is 120-840°, at the base falling to 250° at 4 ft. from the top. The oil take temp. is 200-300° below, to under 100° at the top. The arrangements for oil fractionation mean that the oils are distd. 4 times and that the pitch is coned. automatically.

Cementation of oil wells by the Perkins method. M. ZAVAZKH, *Azerbejdj. Neft. Khoz.* 1928, No. 6-7, 30-2. Bore holes with clay in suspension do not have to be rinsed with water as not only the clay in suspension is removed but also clay on the walls which is in many cases a protection against water and gas. The cement is dissolved in water and clay by thorough agitation. Very satisfactory results are claimed.

Cracking hydrocarbon oils. POWER SPECIALTY CO. Brit. 283,032, April 20, 1927. An app. is described in which oil is cracked by passing through a series of tubes heated to a cracking temp. (the furnace gases being also used to superheat steam for the cracking operation) but so quickly as to avoid appreciable cracking. Details are given as to temps. and app. used for superheating of steam subsequently used in the cracking operation.

Apparatus for cracking hydrocarbons. FRANK A. HOWARD (to Standard Oil Development Co.). U. S. 1,681,899, Aug. 21. A heating coil is located in a furnace chamber where it serves as a screen to absorb radiant heat. Oil to be cracked is passed through the coil into a distn. chamber and vapors from the latter are passed through another coil screened solely by the first mentioned coil.

Apparatus for cracking hydrocarbons. EUGENE C. HERTZEL (to Sinclair Refining Co.). U. S. 1,683,184, Sept. 4. A bed of filtering or absorbent material such as fuller's earth extends entirely across the bulk supply drum of a pressure still below the normal liquid level in the drum; a battery of heating tubes and connections are provided for circulating oil from the space in the bulk supply drum beneath the filtering material through the heating tubes and back again to the space in the bulk supply drum above the filtering material; connections from the upper part of the bulk supply drum carry vapors to a reflux tower, the return from which is led beneath the bed of filtering material, and venting connections are provided between the upper part of the space beneath the filtering material and the space in the upper part of the bulk supply drum above the normal liquid level in the drum. Various other structural details are described.

Distilling petroleum. EDWARD W. ISOM (to Sinclair Refining Co.). U. S. 1,683,135, Sept. 4. Less than a normal charge of crude oil is introduced into a still which is heated and the vapors produced are refluxed until the desired light distillate is removed from the still charge; addnl. crude oil is then introduced to the still in refluxing relation with the vapors and heating is continued with regulation of the feed to obtain the desired light distillate from the reflux tower; when the still is approx. filled the operation is discontinued and the resulting charge is distd. directly to a condenser without refluxing. An app. is described.

Fractional distillation of petroleum. JOHN E. BELL (to Sinclair Refining Co.). U. S. 1,683,150, Sept. 4. Oil contg. a fraction to be sepd. and contg. substantially no components lighter than the fraction to be sepd. is supplied to a vaporizing zone, the vapors from which are passed to a continued refluxing zone; oil lighter than the fraction is independently supplied to the end of the refluxing zone remote from the vaporizing zone, and the fraction to be sepd. is taken off from an intermediate point of the refluxing zone. An app. is described. U. S. 1,683,151 relates to a countercurrent flow of oil and vapors in helical paths in a refluxing column.

Conversion of petroleum oils. GUSTAV EGLOFF (to Universal Oil Products Co.). U. S. 1,682,744, Sept. 4. Oil is heated to a conversion temp. and in the conversion stage is maintained in a shallow body, unvaporized portions of which are recycled for retreatment at a higher temp. than in the initial treatment. The recycled heated oil is passed to the conversion stage where it is maintained in a sep. body and vapors from both the bodies of oil undergoing conversion are dephlegmated and condensate is collected from them. An app. is described.

Apparatus for converting hydrocarbon oils. OSWALD C. BREWSTER (to Standard Oil Co. of Ind.). U. S. 1,681,658, Aug. 21. A chamber is provided for heating a body of oil to conversion temp., from which vapors are led away and from which oil may be passed to a sep. chamber so that the oil in the sep. chamber is brought to oxidizing temp.; fresh oil is also supplied to the sep. chamber and an oxidizing gas such as air is also supplied to this chamber so that the oil in it is brought to conversion temp.; heated oil from the last-mentioned chamber may also be conveyed to the first-mentioned chamber.

Refining hydrocarbon oils. HIRAM J. HALL (to Universal Oil Products Co.). U. S. 1,681,638, Aug. 21. Vapors of hydrocarbons such as those of a cracked petroleum oil are passed through a 20-55% H_2SO_4 soln., to produce colorless gasoline, etc.

Refining hydrocarbon oils. LOUIS BURGESS (to Standard Oil Development Co.). U. S. 1,681,895, Aug. 21. Oil such as a 22.6° B $_6$ petroleum distillate is repeatedly treated with fuming sulfuric acid in the proportion of 5-10%, thus forming sludge and oil-sol. S-contg. compds., and after each treatment the sludge is sepd. and after each sludge sepn. the oil is treated with NaOH and an aliphatic monohydric alc. such as aq. iso-Pr alc. and the alc. soln. contg. dissolved oil-sol. S compds. is sepd. from the oil.

Refining petroleum oils. F. C. AXTELL (to Axtell Research Laboratories, Inc.). Brit. 282,738, Dec. 27, 1926. The S content of oils such as gasoline, kerosene, lubricating oils or cracked distillates is reduced by treatment with a reagent formed from fuming sulfuric acid treated with an excess of C_4H_8 or other aromatic hydrocarbon; an acid sludge contg. most of the S is formed and the aromatic and unsatd. content of the oil is not attacked. The oil may then be treated with a basic clay and with strong aq. alkali soln. and then distd. Selenic acid may be used instead of H_2SO_4 and sufficient SO_2 may be present to combine with any water present or produced on the formation of benzenesulfonic acid. Cf. C. A. 22, 3280.

Refining cracked petroleum distillates. THOMAS G. DELBRIDGE and JOSEPH B. HILL (to Atlantic Refining Co.). U. S. 1,682,603, Aug. 28. Vapors of the distillate are fractionated by contact with reflux liquid, the vapors are condensed and the liquid

condensate, under pressure and at a temp. above its normal b. p., is brought into contact with fuller's earth to effect polymerization of gum-forming and color-imparting compds.; polymers are transported from the fuller's earth by the oil, and the treated oil is distd. to sep. products of lower b. p. from those of higher b. p. contg. the polymers in soln.; the oil of higher b. p. is used as reflux liquid in the fractionation. An app. is described.

Refining mineral oils. FORREST W. LILLY (to Anglo California Trust Co.). U. S. 1,683,288, Sept. 4. In order to remove polymerizable constituents from mineral oil it is subjected to the action of a soln. of ethyl HgAc in ether.

Removing wax from mineral oil distillates. HARRY F. GLAIR and OSCAR R. BRANSKY (to Standard Oil Co. of Ind.). U. S. 1,683,289, Sept. 4. A lighter wax-bearing substantially uncracked oil distillate is mixed with a paraffin wax-bearing oil ment, and the mixt. is chilled and filter-pressed.

Column still and rectifier apparatus for refining oils, etc. SIMPLEX REFINING Co. Brit. 283,383, April 20, 1927. Structural features.

Treating lead sludge from oil refining. JOSEPH B. HILL (to Atlantic Refining Co.). U. S. 1,682,562, Aug. 28. Lead sludge such as is obtained by treating petroleum oil with an alk. plumbate soln. is dried and subjected to dry heat under oxidizing conditions to cause conversion of the major portion of the Pb content to compds. sol. in aq. caustic alkali soln. and such a soln. is then used to dissolve the resultant Pb products. Cf. C. A. 22, 2054.

Treating acid sludge obtained from petroleum refining. ERNEST W. ROTH. U. S. 1,682,713, Aug. 28. A supernatant layer of sludge is heated by means of heat applied to an underlying layer of dil. H_2SO_4 or other dil. acid having a d. greater than the sludge; the acid is maintained at a "simmering" temp. without agitation of the sludge layer. This treatment serves to effect hydrolysis and sepn. of sludge constituents. An app. is described.

Liquid fuel from acid sludge of oil refining, etc. JAMES M. CORY and FRED H. BUNKE (to Solar Refining Co.). U. S. 1,682,369, Aug. 28. Acid sludge is mixed with a filtering medium such as spent clay and a fluxing material such as oil in the presence of steam or other suitable heating agent. An app. is described.

Apparatus for emulsifying oils, etc. WILLIAM THORDARSON. U. S. 1,683,500, Sept. 4.

Apparatus for separating oil and water by gravity. CHRISTOPHER OFFENHAUSER. U. S. 1,682,535, Aug. 28.

Oil from oil shale. HERMAN R. KIPPER. U. S. 1,682,287, Aug. 28. Heated gases are passed through finely ground oil shale to effect distn. and simultaneous mixing and further subdividing of the shale and removal of material from the walls of the distn. chamber are effected by revolving hammers or like devices. An app. is described.

Oil from shale, etc. F. HOFMANN and C. WILFF (to I. G. Farbenind. A.-G.). Brit. 283,159, Jan. 5, 1927. Liquid SO_2 (with or without admixt. of C_6H_6 or other solvent) is used for extg. oil from shale or similar materials such as residues from the destructive hydrogenation of coal.

Halogen treatment of oil shale. GUSTAV EGLOFF (to Universal Oil Products Co.). U. S. 1,682,743, Sept. 4. Aluminiferous oil shale is heated to effect distn., with agitation, in a rotary still, by direct impingement of heating gases, and during the distn. Cl is introduced to unite with the Al in the shale and form AlCl_3 which reacts with hydrocarbons present.

Oil-soluble naphthenic compounds. OSCAR E. BRANSKY (to Standard Oil Co. of Ill.). U. S. 1,681,657, Aug. 21. Oils such as lubricant distillate of Louisiana petroleum are treated with a 10–20% NaOH soln. or other suitable aq. alkali soln. and washed with a dild. alc., to sep. naphthenic acid compds. Cf. C. A. 22, 3041.

Catalytic dehydrogenation of hydrocarbons. I. G. FARBENIND. A.-G. Brit. 283,105, Jan. 3, 1927. Catalytic dehydrogenations such as those constituting the last stage of the process described in Brit. 261,393 (C. A. 21, 3369) are effected in the presence of Cl , with or without addn. of other gases or vapors and at ordinary or reduced pressure. Undue rise of temp. may be avoided by admitting the Cl in small portions or by dilg. it with N , CO_2 or steam. Among the catalysts which may be used are: active C , silica, pumice, Zn borate, V-bearing materials, Al phosphate, Cr oxide and Cu chloride. Actinic rays or silent elec. discharges facilitate the process and the HCl produced may be used in cracking hydrocarbons in the presence of catalysts such as activated Al, Fe or the like, in which case dehydrogenation and cracking may be effected together. Among the materials which may be treated are mineral oils, tars and extn. products.

from coal. Olefins and diolefins may be sepd. from the products and converted into alcs. and used in the *manuf. of synthetic rubber*. Numerous details and modifications are given.

Gasoline from crude petroleum. EDWARD W. ISOM and EUGENE C. HERTHEL (to Sinclair Refining Co.). U. S. 1,683,193, Sept. 4. A body of filtering or absorbent material such as fuller's earth, coke or calcined bauxite is maintained within a vaporizing zone so as to extend entirely across it; oil is circulated from beneath this material through heating tubes and back to the body of oil above the material and is heated to a cracking temp. Crude petroleum is supplied to the circulating body of oil and vapors carrying gasoline fractions are taken off; residual oil is withdrawn from beneath the body of filtering material.

Filter for gasoline. GEORGE F. THOMAS (to Bassick Mfg. Co.). U. S. 1,682,867, Sept. 4.

Filter for gasoline. DOUGLAS F. FESLER (to Bassick Mfg. Co.). U. S. 1,682,807, Sept. 4.

Apparatus for clarifying gasoline (used for dry cleaning) by alkali treatment and sedimentation. PERCY S. PINE. U. S. 1,683,483, Sept. 4.

Apparatus for purifying used lubricating oil by filtration and distillation. EDWARD L. GROSS. U. S. 1,681,980, Aug. 28.

Semi-liquid bituminous composition. JOSEPH H. AMIES. U. S. 1,682,589, Aug. 28. In prepg. a material suitable for use as a *paint* approx. 65 lbs. of granulated bituminous material such as hard asphalt is mixed and heated with 35 lbs. of crude petroleum or similar material, and there is added 15 lbs. of granulated CaO which is already undergoing slaking, and 10 lbs. of crude naphtha. Addnl. naphtha may be used as a thinner.

Acetic acid from wood. FRANCIS G. RAWLING. U. S. 1,681,684, Aug. 21. Wood such as that subsequently used for paper pulp is impregnated with a treating material formed of an aq. soln. of a mixt. of Na_2SO_3 and an alkali such as Na_2CO_3 . The strength of the treating material as used is capable of neutralizing HOAc from the wood but is not sufficient materially to affect the lignin content of the wood; the wood and treating material are heated to 110-160° to form acetates in soln. and the soln. is subsequently rendered acid, e. g., with H_2SO_4 , and HOAc is recovered from the soln.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Cellulose. Its derivatives. P. HAYEMAL. *Ing. chim.* 15, 94 113 (1927).—A lecture on cellulose nitrate and acetate, celluloid and artificial leather. P. T.

X-ray observations on cellulose. R. O. HERZOG AND W. JANCKE. *Naturwissenschaften* 16, 618 (1928).—Cellulose from ramie or bamboo shows for large plate distance (10 cm. or more) close to the central point (shadow of Pb diaphragm) a blackening on the x-ray picture with $\sin \theta/2 \approx 0.0218 \approx 0.0003$. Mercerized ramie has the same characteristic less distinctly. The point would correspond to a lattice period of 35.3 Å. U. (Cu K α radiation); Seemann control of the radiation used eliminated errors from this source. A weak spot at $\sin \theta/2 \approx 0.0885$ would indicate a period of 16 Å. U. perpendicular to the fiber axis, i. e., the double of Polanyi's value.

Lignin. R. WIGGINTON, Sheffield Univ. *Fuel in Science & Practice* 7, 208 72 (1928).—A discussion of the several theories of the chem. constitution of lignin.

D. A. REYNOLDS

New viewpoints on the form of the molecules of cellulose and polymers. J. R. KATZ and P. J. P. SAMWEL. Univ. Amsterdam. *Naturwissenschaften* 16, 592-3 (1928).—A method was worked out for the study of the shape of cellulose mols. by spreading them out in a monomol. layer. Cellulose in ester or ether form, dissolved in CHCl_3 , spreads readily on water and gives a monomol. layer after evapn. of the solvent. The film is slightly compressible. Its surface and thickness were detd. at several pressures and extrapolated to zero pressure. For the dimensions of the film was found: for ethylcellulose high, low or medium viscous or cryst. (Hess) from 60 to 66.5 sq. Å. U. surface, 5.3 to 5.55 Å. U. thickness; for methylcellulose (also 4 types) 59 to 61 and 4.1 to 4.3; for triacetylecellulose high viscous, low viscous, ZnCl_2 -prepd., or cryst. 37.5 to 40.5 and 8.15 to 8.9. Conclusion. Cryst. cellulose prepgs. give values equal to those of technical products, technical products of varying consistency give equal values. The latter conclusion means that the micelles are either string- or leaf-shaped but not

three-dimensional structures. From x-ray evidence the wire shape seems most probable. Polymerization of $C_6H_5IO_3$ must therefore take place in one direction. The results on starch, hichenin and inulin by the same method confirmed this view. Other polymerized substances give similar results. For films of polymerized anethole (by $SnCl_4$) was found, either high or low polymer, 19.5 to 29 sq. A. U. surface, 9.8 to 10.1 A. U. thickness, likewise for polymerized vinyl acetate or methyl acetate. It is probable that in analogy to the fatty acid orientation the moles are all arranged parallel either with their Ph or their acid group at an obtuse angle with the water surface. The work of Gorter and Grendel (*C. A.* 21, 255) on protein moles, is in agreement with the authors' theory.

"Kaoliang" stalk. R. YAMAMOTO. *Cellulose Ind. Tokyo* 4, 53 (6/1928).—The digestion of the kaoliang (*Audrapogon sorghum* Broth), produced in Manchuria, with the soda process and the properties of cellulose obtained from the stalk of kaoliang were investigated from the view-point of the pulp industry. Kaoliang was digested with steam and then with soda to obtain easily bleachable pulp. The most suitable condition for the above process consists of first heating raw material in a closed vessel with 10 parts of water at 100–120° for 30–60 min. and then with soda (12% of the wt. of the raw material) at 130–140° for 3–4 hrs. As raw material, the rind was the best, the leaf and knot were inferior both on account of the small yield, and on account of the difficulties in digestion and bleaching. No pulp could be obtained from the pith alone. The pulp obtained was colored faintly brown. Its yield was 10% and that of bleached pulp was 36%, based on the raw material. Analyses of the bleached pulp and phys. and chem. consts. of the cellulose are given.

The composition of Japanese bamboo. Y. UEDA, K. KASAMA AND K. KIMURA. *Cellulose Ind. Tokyo* 4, 95 (8/1928).—The authors investigated the compn. of Japanese bamboo, Moso Chiku, from the view-point of the cellulose industry. Three specimens (1 yr. old, 3 yrs. old and 5 yrs. old) were used. Though the compn. varied according to age and part of the bamboo used, the results were made separately on the upper, middle and lower parts of the bamboo; the mean compns. of the 3 specimens were, resp.: water 9.39, 8.11, 8.06, ext. with alc. and benzene 2.39, 3.04, 3.02; cellulose 41.56, 42.71, 42.64, pentosans 24.07, 24.36, 24.51. The cellulose contained 4.11% fufural; its Cn. no. was 0.75 and it consisted of α -cellulose 78.92, β -cellulose 17.91, γ -cellulose 3.7%. By acetolysis by Kiern's method, cellulose octaacetate was obtained in a yield of 27% of the cellulose used. By sultolysis by the Monger-William's method, glucose was obtained in 80% yield. By hydrolysis with 7% H_2SO_4 for 5 hrs. crystall. xylose was obtained.

Mannan acetate. I. A new method of preparation of mannan acetate and some of its properties. R. SHINODA AND C. ASHIMAWA. *Cellulose Ind. Tokyo* 4, 6-13 (1928).—Raw "Japanese Konjaku powder" (*Amaranthus* *terrestris*) was treated with aq. soln. of ClO_3 , and the product made into threads in order to be easily treated afterwards. It was coagulated with glacial AcOH and warmed with hot air. The product thus treated was heated on a boiling water bath for about 1 hr. with continuous stirring till the reaction was completed. This method effects an economy of the chemicals used for reaction, e. g. glacial AcOH and Ac_2O , the duration of reaction becomes shorter and no decompn. of konjaku mannan takes place during reaction. The compn. of the mannan acetate obtained was: moisture 11.76, ash 0.42, acetyl group 61.43%, it is apparently the triacetate of mannan. The mannan acetate is very stable and sol. in various org. solvents; the most suitable solvent is the mixt. C_2H_5Cl 4, $AcOMe$ 4, and $MeOH$ 2 parts. In this solvent a 1% soln. has a suitable viscosity, giving a strong film. Though many substances contain mannan, Japanese konjaku powder as a raw material for mannan is the most suitable from an economical point of view. The mannan acetate can be refined satisfactorily by washing it with water.

Preparatory treatments of cellulose acetate rayon. A. KUNZE. *Russa* 3, 745-7 (1928).—Practical operating hints on the desizing, degreasing and bleaching of acetate rayon.

The manufacture of artificial silk, viscose. RAYMOND MORTGAT. *Industrie chimique* 15, 3-6, 66-70, 130-4, 234-8, 290-5 (1928). A study of the com. production of viscose.

Parchment paper and its evaluation. H. SERGER. *Pharm. Zentralh.* 69, 514-8 (1928).—In addn. to detg. the phys. characters, the content of H_2O , H_2O -sol. and insol. mineral ingredients, and sugar is ascertained. The results obtained in the examn. of 10 different samples are presented in tabulated form.

Cotton tissue paper for celluloid. K. ATSUKI AND K. WATANABE. *Cellulose Ind. Tokyo* 4, 141-4 (1928); cf. *C. A.* 22, 867. —By nitration of 5 specimens of cotton tissue

paper the following results were obtained: (1) The larger the degradation of the cellulose, the worse the mech. properties of the film of nitrated cellulose become. (2) The color of the nitrated cellulose is remarkably influenced by that of the original cellulose; the larger the degradation of the original cellulose, the deeper the color of nitrated cellulose. (3) In the nitration the greater the modification of the phys. and chem. properties of the original cellulose, the less is the yield of nitrated cellulose. R. S.

Manufacture of tanning extracts as an improved waste utilization of sulfite liquors from the wood-pulp industry (ESCOURROW) 29. Continuous filters for sludges (adapted for cellulose pulp) (GEISLER) 1. Water of paper mills (WATANABE) 14. Removing and recovering volatile plasticizers from celluloid (U. S. pat. 1,681,692) 18.

Cellulose derivatives. LEON LILJENFELD. U. S. 1,682,292, Aug. 28. Cellulose is treated in the presence of an alkali such as a soln. of NaOH with a monohalo aliphatic acid, *e. g.*, monochloroacetic acid, in the presence of not more than substantially 20 parts by wt. of abs. alc. to every 100 parts by wt. of water present; derivs. are obtained which dissolve in aq. alkalies and are pptd. from their solns. in aq. alkalies by neutralizing agents such as dil. H_2SO_4 or HOAc even when the reaction still remains somewhat alk. and by treatment of their aq. alkali solns. with alc. They are suitable for making films, artificial silk, etc. U. S. 1,682,293 specifies forming films, filaments or other artificial materials from a soln. of a cellulose-glycolic acid or other cellulose-hydroxy-paraffin-monocarboxylic acid (insol. in water) in dil. NaOH soln. or other suitable alkali, by use of a pptg. agent such as H_2SO_4 or HOAc soln. U. S. 1,682,294 specifies treating cellulose with monochloroacetic acid or other suitable compd. contg. the halogen-contg. radical of a monohalo aliphatic acid in the presence of an alkali and an alc., *e. g.*, NaOH and EtOH, while using not more than 0.5 mol. proportion of the monohalo aliphatic acid radical for each mol. proportion of caustic alkali. The product is suitable for making films, filaments, etc.

Sulfonated cellulose derivatives. GEORG KRÄNZLEIN, ARTHUR VOSS and FRANZ BRUNNTRAGER (to I. G. Farbenind. A.-G.). U. S. 1,682,382, Aug. 28. Cellulose is caused to react with an aralkylhalosulfonic acid compd. such as $p\text{-ClCH}_2\text{C}_6\text{H}_4\text{SO}_3\text{Na}$ in the presence of alc. NaOH or other suitable alk. agent. The product thus obtained is sol. in water and may be used for making films or *impregnating textiles*.

Preventing or controlling "delustering" of cellulose derivatives. C. DREYFUS and H. PLATT (to British Celanese, Ltd.). Brit. 282,722, Dec. 30, 1926. Delustering of yarns, fabrics or other forms of cellulose acetate, propionate or cellulose ethers is prevented or controlled by adding thiocyanates such as those of Na, K or NH_4 to hot or boiling aq. baths such as those used for dyeing or bleaching.

Cellulose esters. H. L. BARTHELEMY (to Ruthaldo Co.). Brit. 282,793, Dec. 28, 1926. In esterifying cellulose and nitrocelluloses of low N content, a mixt. is employed contg. an acid anhydride such as Ac_2O and a catalyst such as H_2SO_4 together with a reagent capable of effecting a mild oxidation of the cellulose such as Mn sulfates, Mn acetate, chromic acid, mono-persulfuric acid, manganic and permanganic acid and peracetic acid. By acetylating cotton in this manner, more uniform products are obtained from starting materials of different character than would be produced by processes as previously usually employed, especially as to viscosity characteristics. Brit. 282,794 specifies treating cellulose, before esterification, with a direct oxidizing agent such as Na_2O_2 or other alkali peroxide or H_2O_2 under alk. conditions. Alkali carbonates, silicates, resinates, soaps and Na or NH_4 sulforinates or the like may be added. Cellulose nitrates or acetates thus produced give solns. of low viscosities and produce products of good tensile strength and elongation.

Cellulose esters. I. G. FARBENIND. A.-G. Brit. 283,181, Jan. 6, 1927. Cellulose esters of higher fatty acids, which are sol. in ordinary org. solvents, are made by reaction between untreated cellulose and a chloride of the higher fatty acid such as stearyl chloride, in the presence of pyridine, quinoline or like base, at temps. of 100–140° or even higher. Cf. C. A. 22, 3777.

Molding powders containing cellulose esters. C. DREYFUS and G. SCHNEIDER (to British Celanese, Ltd.). Brit. 282,723, Dec. 29, 1926. A cellulose ester such as cellulose acetate or butyrate or a suitable cellulose ether is pulverized and mixed with dyes, pigments, gums, fillers, plastifiers or softeners or other modifying ingredients. Several formulas are given. Cf. C. A. 21, 1011.

Cellulose acetates. H. L. BARTHELEMY (to Ruthaldo Co.). Brit. 282,788, Dec. 28, 1926. Cotton is first treated with hot HOAc vapors, agitated, allowed to cool

and then mixed with an acetylating mixt. contg. a limited quantity of Ac_2O and more of the latter is added at intervals after the reaction has assumed an equil. (which may be ascertained by examg. the fibers by polarized light or, in the later stages, by detg. the concn. of the soln.). H_2SO_4 or other catalyst may be used.

Cellulose acetates. H. L. BARTHELEMY (to Ruthaldo Co.). Brit. 282,791, Dec. 28, 1926. Acetylation is effected in a cylindrical app. rotating about an axis slightly inclined to the axis of symmetry of the cylinder or in other app., the walls of which are unequally distributed with respect to the axis of rotation. The app. may be provided with coils for heating or cooling and non-corrosive bronze or ceramic material may be used for its construction.

Cellulose acetates. H. L. BARTHELEMY (to Ruthaldo Co.). Brit. 282,789, Dec. 28, 1926. Sulfoacetates formed during the manuf. of cellulose acetates with H_2SO_4 as a catalyst are decompd. by adding to the acetylation mixt. sufficient ac. of formic acid or HOAc to decomp. the excess of Ac_2O while preventing incipient pptn. of the acetate, cooling, and adding a further quantity of formic acid or HOAc and also sufficient HCl to introduce at least as many H^+ ions as were introduced by the H_2SO_4 used as catalyst. The second stage of the treatment may be carried out at a temp. of 41° and an acetone-sol. product may be obtained.

Cellulose acetate soluble in chloroform. HARRY LE B. GRAY and CYRIL J. STAUD (to Eastman Kodak Co.). U. S. 1,683,347, Sept. 4. Cellulose is pretreated with glacial HOAc contg. a mixed catalyst of H_2SO_4 and H_3PO_4 (with at least as much H_3PO_4 as H_2SO_4); Ac_2O is mixed with the pretreated mass to complete the acetylation and the reaction is continued to produce a CHCl_3 -sol. product. The same mixed catalyst serves both in the pretreatment and final acetylation.

Xanthating cellulose. WM. MENDEL (to Samuel A. Neidich). U. S. 1,681,900, Aug. 21. A mass of alkali cellulose is subjected to a vacuum while agitated, to remove air and water vapor; the evacuated mass is then subjected to the action of CS_2 while agitated, until it is transformed into cellulose xanthate; the mass is then again subjected to a vacuum while agitated and fumes of CS_2 are exhausted. An app. is described.

Nitrocellulose solutions and plastics. I. G. FARLEND, A.-G. Brit. 282,172, June 10, 1926. There is used as a solvent the only product obtained by the catalytic hydrogenation of C oxides such as produced by the processes described in Brit. 227,147 (C. A. 19, 2673), Brit. 229,714 (C. A. 19, 3093), Brit. 237,030 (C. A. 20, 1414) and Brit. 238,319 (C. A. 20, 1995) or a fraction of such products, together with various other solvents and admixtures.

Antistatic nitrocellulose film. RAY L. STINCHFIELD (to Eastman Kodak Co.). U. S. 1,683,315, Sept. 4. The rear face of the film is treated with a soln. of an alkali such as NH_4OH until it is superficially hydrolyzed and the treatment is stopped before the flexibility and transparency of the film are impaired.

Artificial silk. H. L. BARTHELEMY (to Ruthaldo Co.). Brit. 282,787, Dec. 28, 1926. Filaments formed by extrusion of a soln. of cellulose ester or ether are coagulated by use of a liquid medium of such a compn. in regard to its rate of absorption of solvent from the filaments as to give the latter the desired properties. Among the materials which may be used are: (a) hydrocarbons with a b. p. above 80° such as toluene, xylenes, dimethylnaphthalene, decane, tridecane, hexadecane, terpenes and polyterpenes; (b) cyclic hydrocarbons such as cyclohexane, methylcyclohexane, tetrahydronaphthalene and decahydronaphthalene; (c) alcs. such as Et, Bu or Pr alc., glycol, glycerol, cyclohexanol, methylcyclohexanol, cyclohexylcarbinol and tetrahydro- β -naphthol; (d) fatty acids of high mol. wt. such as oleic and ricinoleic acids; (e) esters of monohydric alcs. such as oleates and palmitates and Me, Et, Bu, Pr and Am stearates; (f) halogenated compds. such as di- and tri-chloroethylene, pentachloroethane, monochlorobenzene or -toluene, α -bromonaphthalene, 1,2,3-trichlorobenzene and benzyl chloride; (g) nitrites such as "benzonitrite, toluenitrites or xylonitrites"; (h) nitrated compds. such as PhNO_2 and nitrotoluene. Various mixts. of these compds. may be used.

Artificial silk, etc. H. L. BARTHELEMY (to Ruthaldo Co.). Brit. 282,790, Dec. 28, 1926. Filaments, films and the like formed from a soln. of a cellulose ester such as the acetate, formate or nitrate are coagulated by an aq. soln. contg. an emulsifying agent such as an NH_4 or alkali metal salt of oleic, stearic, palmitic or ricinoleic acid or of a sulfonated fatty acid, or Twitchell's reagent, decoctions of panama or quillaia or of a sulfonated fatty acid, or alkali or alk. earth metals, gum tragacanth and wood, egg yolk, caseinates of NH_4 or of alkali or alk. earth metals, borates, etc., water and a higher fatty ternary mixts. of alkali carbonates, phosphates, etc., water and a higher fatty acid. Examples are given of baths also contg. alcs., various hydrocarbons, etc.

Artificial silk. NAAMLOOZE VENNOOTSCHAP NEDERLANDSCHE KUNSTZIJDEFABRIEK.

Brit. 282,721, Dec. 27, 1926. Artificial silk of good tensile strength both when wet and dry is obtained by giving the thread an extended path of travel (at least 50 cm. and suitably 2.5 meters) in the coagulating bath; after this treatment, "viscose silk" may be carried "at an angle" through the air. Cf. C. A. 22, 2863.

Artificial silk. M. F. THOMA (to I. G. Farbenind. A.-G.). Brit. 282,770, Dec. 27, 1926. Staple fibers of artificial silk are prepd. for spinning by treatment in a liquor contg. ingredients for softening, crinkling, increasing the hygroscopicity and improving the feel of the material, e. g., a mixt. formed of water 100 gal., glycerol 3 gal., soda 1 gal., soft soap 0.5 gal., pinol 0.5-1.0 gal. and oil soap flakes 1 gal. Monopol oil, monopol brilliant oil, sulfonated castor oil, sulfonated tallow, sulfonated olive oil, red oil, tetrapole or verapole may be used as softening agents and luster may be produced by enodrine, perperitol, isomerpine, glucose and glycerol. Chlorides of Mg, Ca or Zn may be used for holding moisture in the fiber as may also glucose, acetin or glycerol. Formic acid or HOAc improves the feel of the material.

Artificial silk. COURTAULDS LTD. Fr. 633,957, May 5, 1927. See Can. 282,326 (C. A. 22, 3529).

Artificial threads from viscose. LEON LILIBENFELD. U. S. 1,683,199, Sept. 4. Artificial threads of high "dry tenacity," exceeding 2 g. per denier are obtained by extrusion of viscose into contact with a liquid which contains not less than about 65% sulfuric acid monohydrate. U. S. 1,683,200. See Brit. 281,351 (C. A. 22, 3529).

Apparatus for spinning and drawing artificial silk threads from solutions of cellulose esters and ethers. R. A. J. THENOZ (to Ruthalco Co.). Brit. 283,139-40, Jan. 4, 1927.

Artificial filaments, etc. from viscose. COURTAULDS, LTD., H. J. HEGAN and E. HAZELEY. Brit. 282,973, Dec. 20, 1926. A coagulating bath contg. H_2SO_4 and 25% or more of Na_2SO_4 is used with a viscose contg. 2-4% of added Na_2CO_3 and sufficient NaOH (suitably about 7% or more) so that the proportion of alkali radical is greater than that of the carbonate radical (suitably in the ratio of 4:1). Threads or films thus formed show little inflation and are less lustrous than ordinary viscose "silk" and have an exterior roughness which gives them a feel and appearance similar to that of wool.

Apparatus for forming viscose filaments. SAMUEL A. NEIDICH. U. S. 1,683,478, Sept. 4.

Apparatus for forming filaments of artificial silk and treating them with precipitating liquid. GUSTAV OTTO, AUGUST HARTMANN and GOTTHARD BAURIEDL (to American Bemberg Corp.). U. S. 1,682,797, Sept. 4.

Apparatus for producing filaments of artificial silk. JOHN A. ROUX. U. S. 1,683,055, Sept. 4. A polarizing device is arranged so as to subject the filament to elec. treatment. U. S. 1,683,056 relates to somewhat similar app. and process.

High-speed centrifugal apparatus for use in the manufacture of artificial silk. R. A. BALDWIN. Brit. 283,235, July 9, 1926.

Spinning pump for artificial silk. WICACO SCREW & MACHINE WORKS, INC. Fr. 634,881, May 23, 1927. Constructional features.

Straw pulp and paper. CHARLES H. DEDRICK (to Philadelphia Quartz Co.). U. S. 1,682,834, Sept. 4. In prepg. pulp from straw, the material is cooked with Na silicate, beaten with cooking liquor and then sized.

Paper pulp. GEORGE A. RICHTER and MILTON O. SCHUR (to Brown Co.). U. S. 1,683,262, Sept. 4. Pulp such as that from wood is subjected to alternating chem. treatments and washings. NaOH soln., hypochlorite and Cl may be employed for the chem. treatments and the wash water effluent from one washing is employed in another washing in which the contaminations present in the effluent do not interfere with the other treatments or damage the pulp.

Pulp from waste paper. L. GRENAUDIER. Brit. 282,829, Dec. 30, 1926. In a modification of the process described in Brit. 279,516 (C. A. 22, 3046), ink is removed through the formation of an insol. scum by treating the pulp of the paper which is to be deinked with a very weak Na_2CO_3 soln. (suitably a 0.125% soln.), heating and agitating and if necessary adding a metal salt to form an insol. soap or to effect salting out. Some sol. soap may be added as may also gelatin, albumin, casein, glucose and loading or bleaching agents.

Articles of wood pulp. J. J. H. STURMEY. Brit. 282,929, Oct. 20, 1926. Water bottles, floats or other articles formed of wood pulp are coated (suitably by spray-coating or electrodeposition) with metals such as Fe with a second coating of Cu, Al or Ni.

Pulping machine for paper. ULRICH KIRCHNER. Fr. 634,072, May 19, 1927.

Paper is pulped in a rotating cylinder contg. crushing rollers free to roll on the internal surface of the cylinder.

Beating engine for paper stock. JOHN D. HASKELL (to Dilts Machine Works). U. S. 1,683,546, Sept. 4.

"Doctor" mechanism for paper-making and similar apparatus. N. DUXBURY and G. DUXBURY. Brit. 282,961, Dec. 2, 1926.

Jordan engine for refining paper stock. HERMAN R. HARRIGAN (to E. D. Jones & Sons Co.). U. S. 1,681,935, Aug. 28. Structural features.

Sizing fibrous materials. ALFRED LUTZ (to Ronald C. Lutz). U. S. 1,682,390, Aug. 28. Fibrous material such as paper or cardboard is impregnated with a gelatinous sizing compn. and then treated with a hardening agent comprising methyloformamide, and allowed to stand to effect progressive hardening.

Molded paper articles. LUCIE FENEUX. Fr. 634,652, May 7, 1927. Objects are made in intaglio or in relief by placing a sheet of paper in a mold, then a piece of cloth and then cellulose or paper pulp, which is made by mixing the cellulose or paper in water with alc., flour, gelatin, alum and a powder such as ground glass, sand or metal.

Paper fabric. WILLIAM A. LORENZ (to Otaka Fabric Co.). U. S. 1,682,346, Aug. 28. A material adapted for paper wash cloth purpose comprises a layer of sized pulp and one or more layers of unsized pulp, roughened by embossing or crinkling.

Coated paper. FREDERICK W. PARFELL (to McLaurin-Jones Co.). U. S. 1,683,453, Sept. 4. One side of paper is coated with a filler such as starch or cascan and the opposite side of the paper is coated with an aq. glue and glycerol mixt. or other water-sol. adhesive which is tacky under normal atm. conditions. Paper thus prepd. is suitable for protecting portions of articles during painting by the spray method.

Multi-ply paper. GEORGE L. BIDWELL (to Warren Mfg. Co.). U. S. 1,682,826, Sept. 4. Several wet paper webs are successively picked up upon a pick up felt and the latter with the superposed webs upon its under side is passed through a suction press in contact with a bottom wet felt. An app. is described.

Parchmentizing paper, etc. CARL KNOTT. U. S. 1,683,470, Sept. 4. Paper or like material to be parchmentized is artificially dried, immediately treated with a bath contg. amyloid forming salts such as metal chlorides, removed from the bath and scraped on both sides, squeezed between pressure rollers and heated to mature the amyloid formed, cooked to prevent retrogression or deterioration of the amyloid, and afterward lixiviated, washed and dried.

Waterproofing paper, etc. W. H. CHARCH and K. E. PRINDEL (to DuPont Cellophane Co., Inc.). Brit. 283,109, Jan. 1, 1927. Waterproofing compns. comprise nitrocellulose or similar cellulose ester together with a gum or resin, a wax or wax-like material, plasticizing substance and solvents, etc. Several formulas are given.

24--EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

The detonation-wave in gaseous mixtures and the predetonation period. WILLIAM PAYMAN. *Proc. Roy. Soc. (London)* A120, 90-109(1928).--An adaptation of an old optical device, the "Schlierenmethode" of Topler, has been developed for photographing the invisible shock or compression waves sent out through a gas mixt. on the detonation of a solid or gaseous explosive in the mixt. By this method the pre-detonation period and the inception of detonation in gaseous mixts. has been studied photographically. The observed retardation of the flame in closed tubes is connected with the breaking up of the flame into 2 sep. portions moving in opposite directions. Photographs of the hitherto invisible compression waves show their origin in the gases through which the flame has passed, and in which combustion has commenced some time previously. The waves are due to renewed chem. activity of some kind behind the wave front. The detonation wave also has its origin behind the wave front. The gas mixts. used were $\text{CH}_4\text{-O}$ and $\text{CH}_4\text{-air}$. Photographic comparisons are made of inception of detonation in a H-O mixt. by different initiators (fuse head, powder fuse and detonator).

R. L. DOEGE

Pentaerythritol tetranitrate as a military explosive. ALFRED STETTBACHER. *Z. angew. Chem.* 41, 710-9(1928).--Pentaerythritol tetranitrate (1) is proposed as a bursting charge for high explosive artillery projectiles. Its characteristic properties are: d. 1.62, heat of explosion 1403 kg.-cal., temp. of explosion 4300° , gas vol. 780 l. per kg., rate of detonation 8400 m./sec., Trauzl block expansion 470 cc. lt m. 140-141

hence it cannot be conveniently cast but must be compressed, which decreases its sensitiveness. Shell filled with (A) at a pressure of 6000 atm. have been safely fired at muzzle velocities as high as 800 m./sec. Warmed with *nitroglycerin*, it forms a pasty mass which can be pressed or molded. Such a mixt. contg. 20% *nitroglycerin* has greater energy than the pure tetranitrate and is readily detonated. Either (A) or its mixts. are readily detonated by PbNa_3 . (A) is best prepd. by adding 100 g. pure pentaerythritol slowly to 430 cc. HNO_3 (98-99%) with stirring and cooling (below 25°), then adding 400 cc. H_2SO_4 with continued cooling. The pptd. ester is filtered, drowned in ice water, again filtered, washed and dried. The yield of crude product is 97%. To eliminate entirely occluded acid, 100 g. is dissolved in 400 cc. Me_2CO and 3-4 g. $(\text{NH}_4)_2\text{CO}_3$ added, the soln. filtered into 800 cc. H_2O , the ppt. of very fine crystals washed and dried. Yield, 93-94% theory. (A) gave a negative test with KI-starch paper during successive heatings of 1 hr. at 70°, 2 hrs. at 80°, 2 hrs. at 90° and 3 hrs. at 95°.

C. G. STORM

Gaseous combustion at high pressures. X. The co-volume corrections, maximum temperature and dissociation of steam and carbon dioxide in explosions. DUDLEY M. NEWITT. *Proc. Roy. Soc. (London)* **A119**, 464-80(1928); cf. *C. A.* **19**, 3581. — The corrections to be applied to explosion data in the measurement of internal energies of gases at high temps. are discussed. When greater than 10 atm., the initial pressure must be corrected for deviations from Boyle's law. If the time of the explosion is greater than 0.0005 sec., correction of the max. pressure must be made for cooling of the gaseous medium by the walls of the vessel. The max. pressure must also be corrected for the co-vol. of the gases. Formulas for applying the co-vol. correction are derived. The dissocn. const. for CO_2 in the range 2400° to 2800° abs. as calcd. from explosion data on CO -air mixts. can be represented by the equation, $\log K_p = 7.500^\circ (25,000/T)$. The const. for H_2O dissocn. detd. in a like manner from H_2 explosions were 0.00022 and 0.00060 at 2682° and 2800° abs., resp.

R. L. DONGE

Studying airplane fires. ANON. McCook Field, Dayton, O. *Quarterly Natl. Fire Protect. Assocn.* **22**, 70-84(1928). — A record of actual crash tests made at Wright field with old planes on a specially constructed runway. Slow motion pictures make possible the exact location of the source of ignition at the instant of crash. Ignition systems are a minor cause of fire and explosion compared to exhaust systems. Water cooled exhaust and liquefied CO_2 exhaust attachments were tried, but discarded in favor of air-cooled Al exhaust stacks provided with fins. The latter have been designed to give a max. surface temp. of 370° F., and effectively lessened the percentage of fires in crash tests. Recommendations for fire walls in airplanes, and progress on CCl_4 extinguisher systems for airplanes are briefly outlined.

CHAS. L. JONES

Tests of the severity of building fires. S. H. INGBERG. U. S. Bur. of Standards *Quarterly Natl. Fire Protect. Assocn.* **22**, 43-61(1928). A report on fire intensity-duration tests with office and record room occupancies. Effects of different floor materials, metal vs. wood furniture and shelving, and slow vs. exposure fires were tested in exptl. building. Weights from 10 to 55 lb. per sq. ft. floor area, with available heats of combustion from 8400 to 48,000 B. t. u. per cu. ft. of room vol. were studied and time temp. curves obtained. A table of equiv. fire durations for different occupancies and concn. of combustibles is presented. A table of calorific values of common combustibles is also included.

CHAS. L. JONES

The relation between the explosion temperatures of a powder and its speed of combustion. HENRI MURATRE. *Compt. rend.* **187**, 289-90(1928); cf. *C. A.* **21**, 2799. — In studying mixts. of 50% cotton powder and 50% *nitroglycerin* with increasing % of $(\text{PhNFt})_2\text{CO}$ M. has found that the log of the speed of combustion is in effect a linear function of the temp. of explosion: $V = K_e T_e$, where V is speed of combustion at a pressure such as 1000 kg.; T_e is the temp. of explosion, E is the log base and K and a are const. The temp. of the explosion can be easily calcd. starting from the chem. compn. of the powder using the sp. heats of Neumann and in calcg. the compn. of the explosion products by the method of Poppenberg.

D. H. POWERS

Oxygen concentration for explosion prevention. P. W. EDWARDS AND R. W. HARRISON. U. S. Bur. of Chemistry, Washington. *Chem. Met. Eng.* **35**, 479-81 (1928). — Dilm. of air with CO_2 to 14.1, 15.5 and 13.7% O_2 prevents explosion of dusts of ground cork, pyrethrum flowers, and ground oat hulls, resp.

G. B. TAYLOR

Simplified formulas for specific heats of gases and solids especially of explosion products (YAMAGA) 2. Nitration—a unit process of chemical engineering (GROGGINS) 13. Inflammability of automobile exhaust gases (JONES) 21.

Liquid explosive for driving torpedoes. HUDSON MAXIM. U. S. 1,683,085, Sept. 4. A nitro compd. of glycerol such as nitroglycerin carries in soln. camphor, $C_{10}H_{16}$, acetone and a combustible non-explosive material such as $PhNO_2$ or $C_{10}H_7NO_2$.

Explosives. NOBEL INDUSTRIES LIMITED. Fr. 635,017, May 25, 1927. A propelling explosive contains nitrocellulose with or without nitroglycerol, etc., and an oxidizing substance and an oxidizable substance to give a flashless explosion. KNO_3 and charcoal in the proportions found in black powder, or $K_2Cr_2O_7$ and charcoal may be used, the mixt. being from 0.5 to 25% of the nitrocellulose.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Mechanical dyeing tests in the laboratory. E. SIEFFERLEN. *Tiba* 6, 775, 777 (1928).—A small skein of the yarn (or loose yarn placed in a small wire basket) is immersed in the dye soln. and hung on the end of a vertical glass rod bent into a hook. At the upper end of the rod is a large flat cork. Two flat corks are mounted eccentrically on a small horizontal rod which is placed close to the vertical rod; so that the 2 corks lie one on each side of the vertical rod. On rotating the horizontal rod the 2 corks alternately frictionally engage the cork on the vertical rod, thus turning the latter back and forth and ensuring continuous agitation of the sample in the dye soln.

A. PAPINEAU-COUTURE

Process for dyeing indanthrene dyes on cotton fabrics which have been printed with a plastic reserve. L. K. *Tiba* 6, 913-9(1928).—Practical operating directions.

A. PAPINEAU-COUTURE

Method of dyeing fine deiner artificial silk woven fabrics. B. L. HATHORNE. *Am. Dyestuff Rept.* 17, 544 (1928). L. W. RIGGS

Research and testing at the textile school. THOMAS NELSON. *Proc. Am. Assoc. Textile Chem. Colorists* 1928, 214-5. *Am. Dyestuff Rept.* 17, 536-8.—A description is given of the research lab. of the N. C. State College Textile School. A list of 30 tests made in the lab. of the school at the request of various mills shows active cooperation with the textile industry. L. W. RIGGS

The use of sodium perborate in the textile industry. R. *Tiba* 6, 427, 429, 525, 527, 663, 665 (1928).—Brief practical operating hints on the methods of using $NaBO_3$ in bleaching and dyeing different classes of textiles, with an outline of miscellaneous uses to which it can be put, such as in laundering, prepn. of weak H_2O_2 solns. for household use, removal of stains, bleaching of toilet soaps, prepn. of cotton sizing.

A. PAPINEAU-COUTURE

The cotton manufacturing industry of America. CHAS. F. MULLIN. Clemson College, South Carolina. *Chemistry & Industry* 47, 872-3 (1928). E. H.

Processing cotton pile fabrics. THOMAS J. NUCKOLLS. *Proc. Am. Assoc. Textile Chem. Colorists* 1928, 216-8. *Am. Dyestuff Rept.* 17, 538-40.—Certain features of plush making are described. L. W. RIGGS

Preparation of yarn for the knitter. BURTON MITCHELL. *Proc. Am. Assoc. Textile Chem. Colorists* 1928, 211-4. *Am. Dyestuff Rept.* 17, 533-6. L. W. RIGGS

The degumming of natural silk in presence of acetate rayon. GUILLAUME LARDY. *Russa* 3, 737-43 (1928); *Tiba* 6, 757-63 (1928).—Complete degumming of natural silk yarn can be obtained as completely with proteolytic enzymes (pepsins and trypsin) in presence of 1% of Na_2SO_4 or of $NaNH_2$ phosphate at 35-40° as with the ordinary alk.-soap boiling. With raw silk yarn alone, the goods can be wetted by soaking for 30 min. in soft water at 50°, but for silk acetate union fabrics wetting is carried out by soaking for 1.5-2 hrs. in water at 80-85°. In the former case the goods are washed 90 min. at 60-65° with a 0.5% soap soln. contg. 1 cc. of 20% NH_3 per l.; in the latter case they are washed 2 hrs. at 80-85° with a 1.5-2% Marseilles soap soln.

A. PAPINEAU-COUTURE

Eri silk. FRED GROVE-PALMER. *Am. Dyestuff Rept.* 17, 523-5, 549-50 (1928).—Eri silk is produced in India by the moths *Attacus crythra* and *A. ricini*. The primitive processes of gathering the "wild" silk and prepn. for market are described, also the methods of degumming, bleaching and dyeing. L. W. RIGGS

Cleaning of fur and leather garments. M. H. GOLDMAN AND C. C. HUBBARD. U. S. Bur. Standards. *Tech. Paper* 22, No. 360, 183-97 (1927).—Fur and leather goods retain their color, appearance and pliability during dry-cleaning if a small percentage (1.25% for leather and 2.5% for furs) of paraffin wax, m. 45°, is added to the naphtha.

If, as has been found the case in works' practice, it is undesirable to add the paraffin wax to the cleaning liquor, the material, after cleaning in the usual way, may be soaked in the paraffin wax-naphtha mixt. for about 5 min., centrifuged, and exposed to warm air at a temp. not above 50°. A standard practice for cleaning fur and leather materials is suggested. B. C. A.

The bleaching of straw for hats. L. B. Tiba 6, 767-73 (1928).—A detailed description of the manner in which the bleaching of straw for hats is carried out.

A. PAPINEAU-COUTURE

Action of chlorine on jute fiber. HOWARD W. STRONG. *J. Soc. Chem. Ind.* 47, 196-8T (1928).—The "constants of chlorination" are the amt. of Cl which combined with lignone and the amt. of Cl liberated as HCl. S. detd. these const. for ligno-cellulose of Victoria (Australian) mountain ash, *Eucalyptus regnans* and for jute. The const. of chlorination were unreliable because of destruction of cellulose. With jute Cl chlorinates and also oxidizes. The amt. of Cl combined with the lignone is 5% and corresponds to the formation of a tetrachloro compd. The amt. of Cl as HCl is 10%, these results being in accordance with those obtained in the labs. of Cross and Bevan. S. L. B. ETHERTON

The fastness of dyed fabrics to laundering. R. G. PARKER AND D. N. JACKMAN. *J. Textile Inst.* 19, 223-32T (1928).—In any system of testing dyed fabrics for fastness to laundering, the following points should be considered with reference to the cleansing treatment which must be given: (1) the purpose for which the dyed fabric may be used; (2) the vigor of the cleansing process necessarily employed; (3) the effect of mech motion of a relatively large wt. (50 to 250 lb.) of fabrics in a rotary washing machine; (4) the effect of repeated laundering; (5) effect of wear, exposure to light, moisture, fog, perspiration, etc., also any effects due to textile finishing processes. Directions are given for washing dyed fabrics of different degrees of fastness to laundry processes. Such fabrics are placed in 6 classes ranging from those with very fugitive dyes to those with fast dyes and heavily soiled. I. W. RIGGS

Color, molecular weight and electrolytic character of triphenylmethane derivatives (LIFSCHITZ, GIBBS) 6. Locust-kernel gum and oil [for use in sizing and finishing of yarns] (WILLIAMS) 29. Has the synthetic dye industry been of aid in the development of the rubber industry? (DUBOSC) 30. Mechanism of 2,4-dinitrophenol formation from C_6H_6 and HNO_3 in presence of Hg salts as catalysts (ZAKHAROV) 2. Dyes derived from quinoline 2,3,4-tricarboxylic acid (TEWARI, DUTT) 10. Sulfonated cellulose derivatives [for impregnating textiles] (U. S. pat. 1,682,382) 23.

HARRIS, RENDEL. **A Primitive Dyestuff.** Cambridge W. Heffer & Sons, Ltd. 2s. Reviewed in *Dyer and Calico Printer* 59, 244 (1928).

Dyes. BRITISH DYESTUFFS CORP., LTD., AND JAMES BADDILEY. Fr. 634,907 May 24, 1927. New secondary diazo dyes are prepd. by coupling the diazo compd. of a sulfonated or carboxylated β -nitroarylamine with one of the usual constituents, re-diazotizing and coupling with an aminonaphtholsulfonic acid or a N-substituted deriv., including derivs. of glycine, but excluding as final constituents 2-amino-5-naphthol-7-sulfonic acid, its N-alkyl, aryl or acyl derivs. and its 1-substituted derivs. The above process may be followed by a reduction of the nitro group. Examples and a list of components and the shade obtained with each product are given.

Dyes. BRITISH DYESTUFFS CORP., LTD., J. BADDILEY, P. CHORLEY and R. BRIGHTMAN. Brit. 281,767, Sept. 8, 1926. See Fr. 632,740 (C. A. 22, 3534).

Dyes. BRITISH DYESTUFFS CORP., LTD., AND S. THORNLEY, LTD. Brit. 282,852 Sept. 2, 1926. Flavanthrone is condensed with hydroxylamine in the presence of H_2SO_4 with or without addn. of a metal or metal salt such as $FeSO_4$. The products dye cotton from the vat in green shades and may be converted into other vat dyes by acylation, e. g., with benzoyl chloride, anisoyl chloride *o*- and *m*-methoxybenzoyl chloride, *p*-ethoxybenzoyl chloride, *m*-toluoyl chloride or similar compds. The hydroxylamine may be used in the form of a soln. made by electrolytic reduction of HNO_3 . The final product obtained by use of benzoyl chloride dyes cotton brown.

Dyes. BRITISH DYESTUFFS CORP., LTD., A. SHEPHERDSON and S. THORNLEY. Brit. 282,913, Oct. 8, 1926. Pyranthrone or one of its derivs. such as chloro- or bromopyranthrone is treated with hydroxylamine in the presence of H_2SO_4 with or without $FeSO_4$. Products are obtained which dye cotton from the vat brown shades which are not fast to Cl and by acylation they are converted into other products which can be

purified by hypochlorites and which dye cotton from the vat fast brown. Several examples are given.

Dyes. I. G. FARBENIND. A. G. Brit. 282,807, Dec. 21, 1926. 2-Thionaphthene 2'-indole-indigoid dyes are made by condensing nuclear substituted 3-hydroxythionaphthenes with 5-halogen-7-naphthylsatin 2'-methyl-4'-halogenamides. The products dye cotton violet shades.

Dyes. I. G. FARBENIND. A. G. Brit. 282,804, Dec. 27, 1926. Black copying colors are made by coupling a diazotized dialkylsulfanone with a *p*-cresol contg. an alkylated or aralkylated amino group in the *o*-position to the OH group. Several examples are given, and the products are suitable for use in making copying pencils.

Dyes. I. G. FARBENIND. A. G. Brit. 281,118, Jan. 3, 1927. 2-Thionaphthene-2-indole-indigo dyes are made by condensing a nuclear substituted 3-hydroxythionaphthene with a 5,7-dimethylsatin 2',4'-dimethylamide or a 5,7-dimethyl-4-halogenisatin-2',4'-dimethyl 5-halogenamide or a 5-halo-7-methylsatin 2'-methyl-4'-halogenamide contg. 2 halogen atoms or 2 methyl groups in the 4 and 5' positions. Examples are given of dyes giving violet shades on cotton from the vat. The specified isatin arylides are made by the Sandmeyer process, by way of the thionates from the corresponding amines.

Dyes. J. R. GEGY AKT. GES. Brit. 282,803, Dec. 27, 1926. 1-Chloro-3-diethylisorosinduline-HCl or similar materials are treated with a sulfite such as NaHSO₃ in boiling alc. or other suitable *o*-*s* solvent, the Cl is removed and the leuco 1,6-disulfonic acid is oxidized to produce a dye. Dyes thus formed dye wool from an acid bath blue shades and may be used as intermediate in the production of naphthosulfanone dyes.

Dyes. PAUL LALUËR, to J. R. GEGY AKT. GES., U. S. 1,681,559, Sept. 4. Dyes giving fast blue or reddish blue dyes are made by condensing a *p*-aminophenol deriv. having a sulfo group in *o*-position to the amino group, with various specified isorosindulinesulfonic acids, which have at least 2 sulfo groups, one in the 6-position and a second in the 1- or 2 positions and the third, if present, in any position, and which may also contain various other substituents.

Dyes. SOC. ANON. POUR L'IND. CHIM. A. BALÉ. Brit. 281,713, Dec. 4, 1926. Azo dyes giving fast yellow shades on animal fibers are made by coupling a 2,4-diaminobenzene-1-sulfonic acid acylated in the 4 position, or a nuclear substitution deriv. with a 1-aryl 5-pyrazolone. Several examples are given.

Dyes. SOC. ANON. POUR L'IND. CHIM. A. BALÉ. Brit. 282,782, Dec. 24, 1926. Azo dyes for cellulose esters and ethers are obtained by coupling an unsulfonated *o*-nitrodiazo compd. with 3-methyl 5-pyrazolone. A dye producing fast yellow on "acetate silk" is obtained from diazotized *o*-nitroaniline. 4-Chloro-2-nitroaniline and 3-nitro-4-aminotoluene also may be used as starting materials.

Dyes. SOC. ANON. POUR L'IND. CHIM. A. BALÉ. Brit. 282,783, Dec. 24, 1926. Dyes obtained by coupling *o*-hydroxyazo compds. with 3-methyl 5-pyrazolone are converted into Cr compds. by treating them with agents such as Cr formate, fluoride, acetate or hydroxide or chromic chromate. Several examples are given of dyes producing orange to red shades on wool or silk.

Dyes and intermediate products. BRITISH DYE-STUFF CORP., LIMITED AND ARNOLD SHEPHERDSON AND ANTHONY JAMES HAYWOOD. Fr. 634,686, May 19, 1927. New vat dyes and new intermediate products are prepd. by oxidizing pyranthrone in soln. or acid suspension followed by alkylating, with or without an intermediate treatment with bisulfite soln. and with or without a purification of the oxidized pyranthrone. Examples are given of dyes giving brown and reddish blue shades on cotton from the vat.

Azo dyes. HERMANN WAGNER and OTTO SCHER, to Grasselli Dyestuff Corp.). U. S. 1,681,602, Aug. 21. By coupling 2-amino-4-arylamino-1-alkoxy-, aryloxy- or aralkyloxy-benzenes (obtainable by the action of aryl chlorides upon 2-nitro-4-amino-1-alkoxy-, aryloxy- or aralkyloxy-benzenes and subsequent reduction) with any 2,3-hydroxynaphthoic acid arylides, claret-red dyeings of good fastness to light and kier-boiling are produced. Numerous examples are given. Cf. C. A. 22, 2668.

Secondary diazo dyes. BRITISH DYE-STUFF CORP., LIMITED AND JAMES BADDLEY, PERCY CHORLEY and RICHARD BRIGHTMAN. Fr. 634,781, May 21, 1927. The N-substituted derivs. of 2-amino-8-naphtholsulfonic acids are coupled with diazotized aminoazo compds. to produce dyes which give uniform shades on regenerated cellulose such as viscose. Several examples and a list of compds. which may be coupled and the shades obtained are given.

Anthraquinone dyes. I. G. FARBENIND. A. G. Fr. 635,054, May 27, 1927. 1,4-Diamino-2-alkoxyanthraquinones are prepd. by nitrating 1-amino-2-alkoxyanthraquinone, in which the amino group is blocked, and reducing, or by introducing a halogen

into the 4-position and replacing it by an amino group. Examples are given of the prepn. of 1,4-diamino-2-methoxy- and 1,4-diamino-2-ethoxyanthraquinone. These compds. dye acetate silk in bright shades from red to blue and are very fast. They are also starting materials for other dyes.

Aminoanthraquinone derivatives. SOC. ANON. POUR L'IND. CHIM. A BAËLE. Brit. 282,853, Sept. 21, 1926. Aminoanthraquinones or their derivs. such as aminoanthraquinonesulfonic acids, aminohaloanthraquinones, or aminomethylantraquinones are treated with an aliphatic or aromatic aldehyde such as CH_3O or benzaldehyde in the presence of formic acid, or the starting material may be first treated with one of these reagents and then with the other. The products may be used as dyes or for the production of other dyes, *e. g.*, by reduction, sapon, sulfonation, further condensation, etc. Several examples are given. The dyes, in general, give blue and blue-red shades. Some of them may be used on cellulose acetate.

Isatin derivatives. I. G. FARBENIND. A. G. Brit. 282,863, Sept. 25, 1926. Water-sol. isatin- α -derivs. are produced by the action of sulfites upon isatin α -chloride or its substitution products; the same compds., together with a corresponding quantity of an indigo, can be made by treating dehydroindigo bisulfites with weakly alk. reagents such as Na_2CO_3 , alkali sulfite, borax or very dil. caustic alkali. The new products formed contain 2 S atoms and are stable to dil. hot acids; with concd. inorg. acid they yield chiefly the corresponding indigo and with strong alkalies solns of the corresponding isatins. They can be decompd. by light and by condensation with components such as naphthol, hydroxythionaphthene, indoxyl or acenaphthone produce indigoid dyes. Examples are given.

Phosphotungstomolybdenic compounds and their lakes. I. G. FARBENIND. A.-G. Fr. 634,884, May 23, 1927. The compds. $24(\text{WO}_3 + \text{MoO}_3) \cdot \text{P}_2\text{O}_5 \cdot 3\text{H}_2\text{O}$ and $18(\text{WO}_3 + \text{MoO}_3) \cdot \text{P}_2\text{O}_5 \cdot 3\text{H}_2\text{O}$ obtained by reaction between tungstates, molybdates and phosphates can be reduced by the known reducing agents to give new compds. of phosphotungstomolybdic acid. The compds. are especially suited to the manuf. of lakes stable to light, of basic or acid colors which contain amino groups, substituted or not. Thus the reduction product of the first-mentioned compd. gives a clear red lake with rhodamine B.

Nitro-2,3-dichloro-1,4-naphthoquinone. JOSEF STÖCK (to Grasselli Dyestuff Corp.). U. S. 1,681,599, Aug. 21. This compd., when recrystd. from glacial HOAc or alc., *m.* 175° and forms either yellow needles or laminae. It may be made by reaction of HN_3O_4 and H_2SO_4 on 2,3-dichloro-1,4-naphthoquinone, and may be used as an intermediate in making dyes.

Additions to dye baths. SOC. ANON. POUR L'IND. CHIM. A BAËLE. Fr. 634,742, May 20, 1927. Humic substances, *e. g.*, the substances obtained by treating humic acid with alkalies, are used in dye baths to bring the dye into a fine state of division and to solubilize azo dyes for dyeing acetate silk.

Dyeing. BRITISH DYESTUFFS CORP., LIMITED AND JAMES BABBILEY. Fr. 634,780, May 21, 1927. Cloth made of regenerated cellulose such as viscose silk is dyed by means of monoazo dyes prepd. by coupling 2-amino-5-naphthol-7-sulfonic acid or its N-substituted derivs. with a diazo compd. A list of components for dyes and the color obtained is given.

Dyeing. I. G. FARBENIND. A.-G. Brit. 283,281, Oct. 7, 1926. Acid or basic dyes are fixed on materials such as cotton or artificial silk made from cellulose or cellulose acetate by fixing a complex compd. of a tungstic or molybdic acid or both on the fiber before applying the dye. Numerous examples are given.

Dyeing. SOCIÉTÉ ANON. POUR L'INDUSTRIE CHIMIQUE À BAËLE. Fr. 634,743, May 20, 1927. Cr compds. of dyes obtained from diazo derivs. of *o*-aminophenols and *o*-aminocarboxylic acids are used for dyeing fibers of vegetable origin. Thus, a Cr deriv. of the compd. obtained by coupling 2-diazo-4-chloro-5-nitro-1-phenol and 2,5-aminonaphthol-7-sulfonic acid gives a bluish green on cotton. A long list of components for dyes and the shades obtained with them is given.

Dyeing cellulose acetate. BRITISH CELANESE, LTD., G. H. ELLIS, H. C. OLPIN and W. B. MILLER. Brit. 283,253, Sept. 30, 1926. Dyeing, printing or stenciling is effected by use of unsulfonated nitro derivs. of compds. contg. 2 or more aryl radicals or aromatic residues, 2 of which are united by a single linkage other than N alone. Numerous examples are given among which are the use of 3-nitro- and 3,3'-dinitrobenzidine, 3,3'-dinitro-*o*-tolidine, 3-nitro-4-aminodiphenyl ether, and 3,3'-dinitro-4,4'-di(dimethylamino) diphenyl ketone.

Dyeing cellulose acetate, etc. BRITISH CELANESE, LTD., G. H. ELLIS, H. C. OLPIN and W. B. MILLER. Brit. 283,081, Sept. 30, 1926. Threads, fabrics, films

or other products of cellulose acetate are colored with nitro derivs. of carbazoles, with or without other substituents such as halogen, hydroxy, amino, substituted amino, alkoxy, Me or Et groups, *e. g.*, cellulose acetate woven fabric is dyed bright yellowish green by use of 1-nitrocarbazole solubilized with Na sulfonicoleate.

Dyeing "viscose silk." BRITISH DYESTUFFS CORP., LTD. AND J. BADDILEY. Brit. 283,319, Dec. 10, 1926. Secondary diazo dyes obtained by coupling diazotized *p*-nitroaniline-*o*-sulfonic acid with a middle component (such as α -naphthylamine or *m*-amino-*p*-cresol methyl ether), rediazotizing and coupling in acid or alk. soln. with 2-amino-5-naphthol-7-sulfonic acid or its *N*-alkyl, *N*-aryl or *N*-acyl derivs. are used for dyeing regenerated cellulose silks.

Dyeing animal fibers. J. W. LEITCH & Co., LTD., A. E. EVEREST and J. A. WALLWORK. Brit. 283,347, July 8, 1926. Fibers such as wool or silk (alone or in the presence of other fibers such as cotton or "viscose silk") are dyed by first impregnating the fibers with a dil. neutral or alk. soln. of α - or β -naphthol in the presence of soap or an equiv. org. solvent or dispersing agent and then treating them in a bath contg. a diazotized amine or diamine. Various examples and modifications are given.

Warp-dyeing apparatus. EDWIN E. CARLSON and LAWRENCE A. STEAD. U. S. 1,681,516, Aug. 21.

Textiles. CAMILLE DREYFUS. Fr. 635,028 May 25, 1927. See Can. 280,645 (C. A. 22, 3051).

Coating for textile threads. EDWARD POHL (to Neutrasol Products Corp.). U. S. 1,681,745, Aug. 21. A coating for fibers or threads which is especially suitable for use on filaments of artificial silk comprises beeswax mixed with sapon. Japan wax or other sapon. wax and Na oleate and stearate.

Apparatus for stretching tubular knitted or woven textile materials during mercerizing, dyeing, etc. F. DRIBBLE. Brit. 282,896, Oct. 1, 1926.

Preparing flax, jute and other textile fibers. VICKERS, LTD. AND O. D. LUCAS. Brit. 283,285, Oct. 8, 1926. Materials such as flax, jute, hemp, ramie and sisal after scutching are boiled in a NaOH soln. of not over 2% strength and then, with or without intermediate washing, are boiled in a mixt. of linseed oil or other suitable oil and alkali and may then be washed and treated with a cold bath contg. HCl or HOAc, which also may contain a small proportion of NaOCl or Cl.

Bleaching linen, hemp, jute, etc. I. G. FARREND. A.-G. Fr. 635,014, May 25, 1927. Vegetable fibers which are difficult to bleach are treated after a preliminary boiling with a soln. of hypochlorite at the ordinary or a slightly raised temp. and then without rinsing with a soln. of permanganate. After rinsing, the deposit of MnO₂ is removed by a soln. of bisulfite, and the material is boiled with an alk. lye contg. reducing salts. To obtain a perfect white a final bleaching with H₂O₂ made alk. with Na₂SiO₃ is used.

Bleaching and hydrophilization of vegetable textiles. RAYMOND VIDAL. Fr. 634,902, Sep. 24, 1926. Crude textiles are bleached and made absorbent by treating with alkali hypochlorite soln. contg. about 10 g. of soap per l.

Weighting natural silk. RENÉ CLAVEL. Fr. 634,641, Apr. 16, 1927. Acids or acid salts are added to the bath of metallic salt, *e. g.*, SnCl₄, to increase the acid concn., and then the silk is introduced without washing into a bath of phosphate or H₃PO₄.

Protective colloids may be added to the SnCl₄ bath.
Weighting silk. R. CLAVEL. Brit. 283,019, March 24, 1927. The process described in Brit. 266,640 (C. A. 22, 690) is modified by incorporating the acid substance, for increasing the acid concn. of the metal salt bath, with the silk before the latter has been brought into the bath, and maintaining a lower acid concn. of the weighting bath or omitting the addn. of acid or salt to that bath. A protective colloid may be used with the acid substance in the preliminary treatment of the silk. Various details and examples are given.

Decoration of cloth, leather, etc. BRITISH RIBB PRINTERS, LIMITED AND JULIUS CATO VANDENBURG and FÉLICITÉ ANTOINE HENRI HEINERT. Fr. 635,025, May 25, 1927. See Brit. 277,991 (C. A. 22, 2146).

Printing on felt. BOSSÉ HUTFAHRIS-A.-G. Brit. 283,183, Jan. 11, 1927. In printing on hat bodies or the like, the colors are applied to the felt before it is fully milled; the final milling destroys the sharp outline of the design and gives the felt the appearance of a woolen fabric.

Felting. JOHN HENRY MARTIN. Fr. 634,662, May 18, 1927. Hairs to be used for hat making, etc., are treated with an org. or inorg. salt of Mn. in neutral or acid soln.

Treating crepe waste. GEORGES BONNARD. U. S. 1,683,520, Sept. 4. The waste is run through a waste-opening machine to break up the threads into approx.

Use of synthetic resins for making cages or retaining rings for ball and roller bearings. COMPAGNIE D'APPLICATIONS MECANIQUES. Brit. 282,719, Dec. 28, 1926. Natural resins and fillers may be used with the synthetic resins.

27—FATS, FATTY OILS, WAXES AND SOAPS

R. SCHERUBEL

Report on (the analysis of) fats and oils. G. S. JAMIESON. Bur. of Chemistry and Soils, Washington, D. C. *J. Assoc. Official Agr. Chem.* 11, 301-8(1928); cf. *C. A.* 21, 3474.—Collaborative results showed that both the Thomas-Yu method (*C. A.* 17, 645) and Evers' modification (*C. A.* 7, 662 of Bellier's method (*Ann. chim. anal.* 4, 4(1899)) give high results, and that neither of them, as now formulated, gives satisfactory results in mixts. contg. 15% or more of peanut oil. Collaborative results on the detn. of satd. and unsatd. fatty acids in corn oil, cottonseed oil and peanut oil by the Pb-salt-Et₂O method and by the Pb-salt-alc. (Twitchell) method showed fairly good agreement, especially in view of the difficult technics involved. Though the Twitchell method is supposed to give a satd. acid fraction contg. so little unsatd. acids as to require no correction, it was found that the satd. acids sepd. frequently had an I no. of 4 or more.

Analysis of edible oils. A. FALCONE. Univ. Palermo. *Ann. chim. applicata* 18, 273-86(1928).—The increasing adulteration of olive oil with other vegetable oils induced F. to undertake a systematic series of expts to ascertain whether these oils can be identified by simple tests. To olive oil was added in various proportions (10, 20, 30, 40, 50 and 60%) peanut, sesame, rape seed, colza, soy bean, cottonseed, corn, grape seed and poppy seed oils and the d., thermal const. with H₂SO₄ (Tortelli) and η value were detd. for each mixt. The results are tabulated in complete detail, and show that it is possible to identify the presence of any of these oils in olive oils by detg. the 3 consts. mentioned, i. e., the 3 consts. of each mixt. of olive oil and the other oil when considered together are characteristic enough to allow the oil to be distinguished from other combinations.

Oil from *Pinus gerardiana*. Chilgoza oil. I. S. D. HARDIKAR. *J. Indian Chem. Soc.* 5, 63-7(1928).—The kernels of this tree, indigenous to North-West India and Afghanistan, contain 33.7% of an oil which consists of glycerides of linoleic and oleic acids (over 93%) and of satd. acids (about 5%). The esters of linolenic acid are absent. The oil has d_{20} 0.9144, n_D^{20} 1.4709, acid value 3.87, sapon. value 192.4, acetyl value 4.07, I (Hubl) 121.3, unsapon. matter 0.50.

Presence of an aliphatic acid hitherto unobserved in a fish oil. HENRI MARCELET. *Compt. rend.* 187, 145-6(1928).—The satd. acids were sepd by means of their Pb salts and fractional crystn. in alc. from the oil of *Dorosoma naysus* Bloch. The most abundant fraction, which m. 55°, was purified by further recrystns. when its m. p. was fixed at 55°. Analysis of this fraction gave the formula C₁₇H₃₄O₂. The neutralization index, mol. wt., Ba and Pb in salts and the m. p. of its Me ester confirm the presence of a new acid for which the name *dorosomic acid* is proposed. The properties and consts. of this acid approach those of daturic acid obtained from the oil of the seeds of *Datura stramonium*.

Pachira aquatica Aubl. J. PIERRAERTS, N. IPATIEFF AND E. SIMAR. *Mal. exsasses* 19, 8000-1(1927); 20, 8056-8, 8085-6, 8113-4, 8252-4(1928).—The seeds from *Pachira aquatica* contain H₂O 14.3% and oil 25.26%. The kernel contains H₂O 19.3%, ash 6, oil 39.11, rosin and coloring matter, glucose 0.88, fecula 6.00, proteins 13.3, gem 0.49 and extractive matter 16.02%. The butter of *Pachira* kernel has a sp. gr. of 0.9286. Detailed analysis is given of different parts of the seed: the carpal wall, the hair lining, the inside and the shell. The ash of the shell is rich in K, Al, Ti, Mn and Al. The ash of the kernel is similar in some respects to that of the Cola nut, but contains less P, Fe and Mn. A table shows the characteristics of the different oil-producing plants and that from *Pachira*. The oil cake is free from glucosides and sugars (triose and tetrose) but probably contains saccharose. The oil extd. from the kernels m. 29-29.5°, n_D^{20} 1.4653, d_{20} 0.9184-0.9218, sapon. index 191.9-202.6, ether value 177.83-200.95, I value 55.47-58.24. The acids contained in the glycerides consist of oleic, linoleic and palmitic acids. It has been impossible to find stearic, arachidic and myristic acids. Exptl. data are given.

P. THOMASSET

Centrifuge for the purification of oil (Fr. pat. 634,903) 1.

LÖFFL, KARL: *Technologie der Seifenfabrikation*. Stuttgart: F. Enke. 426 pp. M. 27.—; cloth, M. 29.—.

Steam-jacketted apparatus for extracting oils from rape seed, oil-saturated fuller's earth or other materials by use of solvents. P. L. FAUTH. *Brit.* 283,216, Jan. 7, 1927.

Soap. RAYMOND VIDAL. *Fr.* 634,983, Sept. 28, 1926. Soaps sol. in water are prepd. by the action of alkali hypochlorites or aldehydes, particularly AcH and furfural, on mixts. of mineral oils and fatty acids or oils or fats. The soaps are used in the treatment of textiles.

28—SUGAR, STARCH AND GUMS

F. W. ZERBAN

The composition of commercial sugar from Philippine centrals. DELFIN J. SUERTE. Univ. of the Philippines, Los Baños. *Philippine Agr.* 17, 149–51 (1928).—Samples representing 265,727 metric tons or 56% of the 1926–7 crop of raw sugar gave the following av. analytical results: polarization 96.66°, gums 0.68, suspended solids 0.10, moisture 0.87 and ash 0.30%. The latter contained $\text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$ 0.86 \pm 0.01, P_2O_5 4.58 \pm 0.04, CaO 8.58 \pm 0.04, MgO 3.10 \pm 0.05 and K_2O 48.86 \pm 0.06%.

A. L. MEHRING

Recovery of potassium salts and other alkali compounds from molasses in the sugar industry. TEOFILO GASPAR Y ARNAL. Univ. Centrale de Madrid. *Chimie et industrie* 20, 27–28b (1928); cf. *C. A.* 20, 2129, 2297; 21, 1942.—G. has studied experimentally the pptn. of alkali salts (chiefly K salts), which gives $\text{CaK}_2\text{Fe}(\text{CN})_6$ (soly. 0.34%). A recovery of up to 62.5% of the sucrose in the filtered molasses can be obtained; and the reagent may be recovered from the ppt. by treating with a suitable metallic salt (preferably $\text{Fe}_2(\text{SO}_4)_3$ on economic grounds). The reactions involved in the recovery of the pptg. reagent are $3\text{K}_2\text{CaFe}(\text{CN})_6 + 2\text{Fe}_2(\text{SO}_4)_3 = \text{Fe}_4(\text{Fe}(\text{CN})_6)_3 + 3\text{CaSO}_4 + 3\text{K}_2\text{SO}_4$; $\text{Fe}_4(\text{Fe}(\text{CN})_6)_3 + 6\text{Ca}(\text{OH})_2 = 3\text{Ca}_2\text{Fe}(\text{CN})_6 + 4\text{Fe}(\text{OH})_3$; $4\text{Fe}(\text{OH})_3 + 6\text{H}_2\text{SO}_4 = 2\text{Fe}_2(\text{SO}_4)_3 + 12\text{H}_2\text{O}$. The recovery process and equipment required to carry it out are described. Treatment of 1000 kg. of molasses requires 200 kg. of $\text{Ca}_2\text{Fe}(\text{CN})_6 \cdot 12\text{H}_2\text{O}$, 110 kg. $\text{Fe}_2(\text{SO}_4)_3$ (80.8 kg. H_2SO_4) and 60 kg. $\text{Ca}(\text{OH})_2$ and yields 312 kg. crystd. sucrose, 311.5 kg. crude molasses (a final sucrose content of 50% and a loss of 10% of the treated molasses being assumed), 194 kg. $\text{Ca}_2\text{Fe}(\text{CN})_6 \cdot 12\text{H}_2\text{O}$, 79.5 kg. of 90% K_2SO_4 and 70 kg. of pptd. CaSO_4 . The process could be used for the treatment of other low-grade sugar-house products. A. PAPINEAU-COUTURE

Obtaining products from the waste liquor after distilling alcohol from fermented beet molasses (U. S. pat. 1,681,379) 16.

Purifying sugar juices. F. BLANKE. *Brit.* 283,202, Jan. 8, 1927. Automatic satn. of sugar juice by CO_2 or SO_2 is effected by causing the juice to flow from a tank in which its level is restored into an ascending pipe under pressure of the gas, with supply of air under elec. control depending on the elec. cond. of the juice. Various details of app. are described.

Apparatus and filtration system for producing sirups from sugar. FRANK B. LOMAX. U. S. 1,681,490, Aug. 21.

Apparatus with a funnel-shaped settling chamber, for thickening and clarifying materials in sugar production, etc. HENRY G. SCHWARTZ. U. S. 1,682,256, Aug. 28.

Dextrose. CORN PRODUCTS REFINING COMPANY. *Fr.* 634,927, May 24, 1927. To increase the content of dextrose in solns. from the acid hydrolysis of starch, a second conversion is carried out in the absence of catalysts to hydrolyze the polysaccharide impurities formed by the catalysts.

29—LEATHER AND GLUE

ALLEN ROGERS

Indirect determination of the dry weight of the hide by means of the hydrostatic balance. ANDREA PONTE. *Boll. ufficiale staz. sper. ind. pelli mat. concianti* 6, 84–92, 97–107, 130–44, 150–5 (1928); cf. *C. A.* 22, 2485.—The theory on which the application of the hydrostatic balance in the tannery is founded is given in detail. G. S.

Progress in the field of rapid tanning. I. WEISSBERG. *Vestnik* (Organ of the All-Russian Leather Synd.) No. 11, 465-7(1927); *Collegium* 1928, 362-3.—The time required for the whole process of leather manuf. is very much shortened by the following working methods: (1) rapid liming with $\text{Ca}(\text{OH})_2 + \text{Na}_2\text{S}$ in drum without previous soaking (about 24 hrs.); deliming to $p_{\text{H}} = 5.5$; rapid tannage with exts. in vats and drum (8-14 days), or "ultra-rapid tannage" in drum only (4 days); (4) use of hydraulic press and scientifically constructed drying tunnels for dewatering. Also in *Gerber* 54, 81-3(1928). H. B. M.

Manufacture of tanning extracts as an improved waste utilization of sulfite liquors from the wood-pulp industry. R. ESCOURROU. *Chem. Märkts* 23, 153-5(1928); *Halle aux cuirs* 1928, 203-14, 234-46; cf. C. A. 22, 2854.—A review, especially of patents. E. H.

Tannery-technological characteristics of tanning extracts. P. PAVLOVICH. *Vestnik* (Organ of the All-Russian Leather Synd.) No. 1-2, 39-44(1927); *Collegium* 1928, 363.—The claim often made that tanning exts. are inferior to the crude bark or wood, due to destruction of tannase during hot water extn., is refuted. Comparative tanning tests with raw mimosa bark (1) heated to 100° for 10 min. to destroy tannase, and (2) unheated, gave identical results. Comparative tanning tests with blended raw materials and the hot water ext. thereof, resp., gave results strongly favoring the exts. H. B. MERRILL

Utilization of tanning materials containing a large amount of soluble non-tannins. P. A. YAKIMOV. *J. Chem. Ind. (Moscow)* 5, 507-9(1928).—Further investigation has been made on the method of Smetkin and Yakimov (cf. Sadikov and Yakimov, C. A. 22, 2681) which is based on the difference of speed of dispersion of nontannins (crystalloids) and tannins (colloids) through the cells of badan bark which are acting as a semipermeable membrane. It was found that dialysis does not really take place when powd. badan bark is used, since in that case the cells are destroyed and both the crystalloids and the colloids diffuse freely; the only reason why the non-tannins diffuse at a faster rate than the tannins during the first extn. is that their mols. are more mobile. It is, therefore, advisable to operate with fairly large pieces of the bark so as to avoid damaging the cells. The results seem to be very good and the method is now in operation on a factory scale, the pine bark also being treated in the same manner. This is a preliminary communication and details are not given. BERNARD NELSON

Determination of insolubles [in tanning extracts] by filtration in the presence of kaolin. A. JAMET AND A. J. GIRARD. French Tanning School, Lyon, France. *J. Intern. Soc. Leather Trades Chem.* 12, 279-81(1928).—The international method for tannin analysis does not prescribe the fineness of the kaolin used in filtration. By fine grinding a com. kaolin, the % insol. matter found in exts. was increased from 2.4 and 3.75% to 3.3 and 8.3% for chesnut and quebracho, resp. Another kaolin gave higher results for insol. matter than the preceding, both before and after grinding. A kaolin was sepd. into particles of 3 degrees of fineness by screening, and each portion used for filtration of exts. in the detn. of insol. matter. For chesnut ext. the % insol. matter found was 4.3% for very fine kaolin, 3.75% for medium and 1.85% for coarse. The corresponding figures for quebracho were 9.9, 7.1 and 5.8%. These results indicate that it will be necessary to prescribe the fineness of the kaolin used for filtration of tanning exts. H. B. MERRILL

Different types of high-grade calcium limes and their application to the leather industry. D. F. WASHBURN. Am. Lime and Stone Co. *J. Am. Leather Chem. Assn.* 23, 441-51(1928).—High Ca limes are classified as quick, medium and slow slaking. Methods for distinguishing these types are described. It is believed that the same slaking conditions that give the best results with each type in the building industry will also produce the best milk of lime for the leather industry; i. e., a finely divided suspension of slow settling rate, affording rapid replacement of dissolved lime used up in the unhairing process. The best methods for slaking the different types are described. In general, quick slaking limes should be treated with an excess of water and precautions taken to avoid rise in temp.; slow slaking limes must be treated with the min. amt. of H_2O , preferably hot, and precautions taken to conserve the heat developed. H. B. MERRILL

Some physical characteristics of chromium sulfate solutions. W. J. CHATER AND J. S. MUPP. Northampton Tech. College, Northampton, Eng. *J. Intern. Soc. Leather Trades Chem.* 12, 272-79(1928).—The relation between basicity, p_{H} value and neutral salt content was studied for solns. of pure $\text{Cr}_2(\text{SO}_4)_3$, adjusted to different basicities with NaOH and all contg. equal concns. of neutral salt. For liquors contg. 1%

Cr and 0.158 *M* Na₂SO₄, the *p_H* value rises with basicity with a marked point of inflection at acidity = 0.84 (124 parts acid sulfate as H₂SO₄ per 52 parts Cr). For chrome alum liquors of the same Cr and added Na₂SO₄ content, *p_H* values are higher than those of the Cr₂(SO₄)₃ liquors at acidities less than 0.84, and lower at acidities above 0.84. Conductance of the pure Cr₂(SO₄)₃ liquors 0.158 *M* in Na₂SO₄ falls with the acidity to a min. at acidity = 0.84 and thereafter rises. Conductance of K₂SO₄-Cr₂(SO₄)₃ liquors 0.158 *M* in Na₂SO₄ falls with the acidity to a minimum acidity = 0.84 and is thereafter const. Acid penetration and Cr penetration into gelatin decrease with increasing basicity or *p_H* value.

H. B. MERRILL

Comparative data on vegetable and chrome-retanned sole leather. R. W. FREY, I. D. CLARKE and L. R. LEINBACH. Bur Chem., U S Dept Agr. *J. Am. Leather Chem. Assn.* 23, 430-41 (1928).—Six uniform steer hides were cut into sides, and corresponding sides trimmed to exactly the same size and shape. One side from each hide was vegetable tanned, and the other chrome-tanned. Two chrome-tanned sides were given a light vegetable retannage, 2 a medium and 2 a heavy retannage. The av. yield for vegetable sides was 66% of cured weight; for chrome-retanned sides 40%. The yield of chrome-retanned sides increased with the extent of retannage. The av. area of vegetable sides was 104% of the cured area; of chrome-retanned sides, 94%. The av. thickness of vegetable soles was about 8 irons, of chrome-retanned soles (light or medium retannage) about 7 irons, of heavily retanned chrome soles about 8 irons. The av. apparent density of vegetable leather was 1.061, of lightly retanned chrome leather, 0.704, of medium retanned chrome leather, 0.720, and of heavily retanned chrome leather, 0.827. The av. tensile strength of vegetable leather was 4608 lb. per sq. in., with a stretch of 19% at breaking load; of chrome-retanned leather, 3357 lb. per sq. in. and 26% stretch. The strength of chrome-retanned leather decreases with the extent of retannage.

H. B. MERRILL

Comparison of four machines in the preparation of leather samples for analysis. I. D. CLARKE and R. W. FREY. Bur. Chem., U. S. Dept. Agr. *J. Am. Leather Chem. Assn.* 23, 412-29 (1928).—Four machines are compared. (1) a circular saw machine, (2) Pfister and Vogel machine (*C. A.* 20, 516), (3) Wiley mill and (4) Balderston machine. Five leathers were put through each machine: (1) heavy vegetable-tanned sole leather, (2) heavy vegetable-tanned harness leather, (3) russet strap leather (4) latigo leather and (5) heavy chrome-tanned, waxed sole leather. The latigo leather could not be prepd. on the circular saw or Pfister and Vogel machines, and the prepn. of the strap leather by the circular saw machine was tedious. The time required was least with the Wiley mill, and greatest with the circular saw machine. The sample prepd. by the Balderston machine consists of tiny slices about 0.01-0.02 mm. thick. Samples prepd. by the other machines are fibrous. All samples lost H₂O during processing; loss was least with the Balderston machine; all samples returned to original H₂O content on reconditioning at original relative humidity and temp. Analytical results on leathers cut up by the several machines were identical, except for sol. tannin, which was lower for the samples cut on the Balderston machine, because of greater dimensions of particles. From a performance point of view, the choice rests between the Wiley mill and the Balderston slicer. The Wiley mill may be better adapted to very thin leathers.

H. B. MERRILL

Determination of sulfuric acid in vegetable-tanned leathers. R. FARADAY INNES Brit. Leather Manufacturers' Research Assn., London, Eng. *J. Intern. Soc. Leather Trades Chem.* 12, 256-71 (1928).—Existing methods are reviewed. The Procter-Searle and Wunsch methods include as H₂SO₄ much S not present as H₂SO₄ in the leather. The Thomas method is not applicable to vegetable leather, since the leather is decomposed by boiling. Other methods depending on the detn. of H₂SO₄ in H₂O ext. are in error because of the incomplete extn. of acid from the leather. The method of Cohn and Crede, in which the titration curve of the water ext. is obtained, is an advance on previous methods, since information is afforded as to the strength of the acid in the ext. Expts. showed that all the sulfate in vegetable leather is removed by soaking in 0.2 *N* NaHCO₃ for 24 hrs. Total sulfate detd. in the NaHCO₃ ext. is referred to as "gravimetric sulfate." In the "gravimetric method" S combined in syntans is not displaced. About 75% of total H₂SO₄ is removed by soaking in water for 24 hrs. The *p_H* value of this water ext. before and after 10-fold diln. tells whether a strong acid is present in the leather. If H₂SO₄ is present the increase in *p_H* value on 10-fold diln. is referred to as the "difference figure," is always more than 0.7 *p_H* unit. H₂SO₄ is present in the leather only when positive results are obtained by the Procter-Searle method, the gravimetric method and the "difference figure" method. A difference figure of 0.7-1.0, pos. Procter-Searle, and neg. gravimetric results indicates the presence

of syntans. A difference figure of 0.7-1.0, negative Procter-Searle, and positive gravimetric results indicates the presence of oxalic acid and neutral sulfate. H. B. M.

Locust-kernel gum and oil. A. L. WILLIAMS. *Analyst* 53, 411-5 (1928).—Locust-kernel gum, gum tragon and tragacanth contain a mucilaginous substance from the endosperm of the locust or carob bean. These products, mixed with cold water, stirred and heated, yield an opaque, tasteless and colorless mucilage which is used as a restraining influence in tanning so that rapid tannage with strongly astringent liquors can be effected without detriment to the finished product. It is also used in the sizing and finishing of yarns, for thickening the color paste used in calico printing and as a thickener of edible sauces. The reactions with tannin, borax and Fehling's soln. appear to be the most characteristic tests. With an excess of tannin a buff-colored clot is pptd. with a clear, supernatant liquid. On heating the gel is dispersed but reappears on cooling. It is also dispersed by sugar and by glycerol, etc. The ppt. when washed with alc. is sol. in water, like the original substance. With borax a solid jelly is formed which is liquified by adding an excess of reagent or some acid. With Fehling's soln., a blue mass is pptd. which is sol. in acids. Apparently locust kernel oil contains a sol., non-volatile, fatty acid of high mol. wt. Ground kernels from which the oil had been extd. contained water 12.08, ash 2.80, oil 1.80, albuminoids 15.12, fiber 6.10 and carbohydrates 62.10%. W. T. H.

Cellulose. Its derivatives [artificial leather] (HAYEMAL) 23. Cleaning of leather garments (GOLDMAN, HUBBARD) 25. Decoration of leather (Fr. pat. 635,025) 25.

Leather. H. FLEISCH. *Brit.* 282,710, Dec. 27, 1926. Highly sulfonated Turkey-red oils contg. over 6% of organically combined sulfuric acid are used in chrome tanning or other tanning processes or for pretreatment or finishing of the leather. There may also be added oxy. acids such as formic, acetic, propionic, butyric, lactic or oxalic acids or their salts or esters.

Depilatory. RENE BOTSON (to Soc. industrielle des applications chimiques). U. S. 1,683,442, Sept. 4. See *Can.* 275,518 (*C. A.* 22, 1249).

Machine for stretching and softening skins. DANIEL MERCIER. *Fr.* 634,776, May 21, 1927.

Tanning compositions containing sulfur. OSKAR SPEGLER and ALFRED THURN (to I. G. Farbenind. A.-G.). U. S. 1,682,434, Aug. 28. Products which form dry powders which are only slightly hygroscopic are obtained by reaction between an hydroxyaryl-carboxylic acid sulfochloride and an esterified hydroxyaryl compd., e. g., between salicylic acid sulfochloride and acetylsalicylic acid at 175-180°.

Chrome leather impregnated with nitrocellulose and glycerol. LYMAN F. WHITNEY and WILLIAM E. WHITNEY (to Rajet Co.). U. S. 1,682,652, Aug. 28. A material is described suitable for use as sole leather.

Polish for leather. HENRY MAZEAU. *Fr.* 634,792, Apr. 4, 1927. A waterproof polish is made by warming together pure beeswax, carnauba wax, spermaceti, water, turpentine and K_2CO_3 .

Conditioning coated materials such as "patent leather." GORDON D. HARRIS (to Industrial Dryer Corp.). U. S. 1,682,752, Sept. 4. The coated surface is treated with a circulating oxidizing atm. contg. volatile substances evolved from the coating compn. and is thereafter treated with fresh atm. air of regulated moisture content. An app. is described.

Investigations on the structure of rubber. PAUL BARY AND ERNST A. HAUSER. *Rev. gén. caoutchouc* 1928, No. 42, 3-11.—The paper is a reconciliation of the previously independent and divergent views of B. and of H. Three problems have marked the general course of expts. up to the present (1) the existence of 2 components; (2) the conversion of 1 component into the other, and (3) the structure as judged by x-ray examn. At present there is confusion over the nomenclature of the 2 components of rubber, and it is strongly recommended that the term α -rubber for the Et_2O -sol. component and the term β -rubber for the Et_2O -insol. component be adopted. The difference between α - and β -rubber lies chiefly in the fact that in α -rubber the primary valence chains (united in bundle form by secondary valences) are smaller than in β -rubber. A discussion of the relation of the most recent work on the viscosity of rubber solns. in its relation to the reversible transformation of α - and β -rubber indicates that the 2 components are in equil. under conditions similar to those of a jelly. To do away with the confusion existing in the subject of the no. of phases in a rubber system, the attempt is made to define precisely the concept of a jelly and a gel. Unstretched rubber is a jelly, i. e., a soln. or homogeneous system of 2 or more rubber polymers. Stretching of rubber causes a swelling and transformation into a gel. A gel is a substance which consists of at least 2 phases, where the degree of dispersion of 1 phase in the other is of little significance. The results already obtained with x-rays are discussed, attention being called to the false conclusions which may easily be drawn from x-ray data. As a result of the review and discussion, certain conclusions may be drawn regarding the structure of rubber. Rubber contains 2 components of the same elementary chem. compn. but of different degrees of polymerization and of differing fluidity. The component with the greater fluidity is the one with the lower degree of polymerization. The proportions of these 2 components vary so that if α and β are the mean values of the degrees of polymerization and n_1 and n_2 are the nos. of mols., resp., then the ratio $n_1\alpha/(n_2\beta)$ varies with the temp. and with the mech. treatment. At ordinary temp. and at temps. a little lower, the value of $n_1\alpha/(n_2\beta)$ is very low for rubber at rest, but it is increased by work and heat, e. g., by repeated stretching. The fact that "frozen" rubber in an unstretched condition gives Debye-Scherrer-Hull rings, where the proportion of β -rubber has increased at the expense of the α -rubber, indicates that the less diffusible component is responsible for the x-ray diagram. In the elongation of normal rubber (not "frozen"), the α -component, which is dissolved in the β -component to form a jelly (by the definition proposed), seps. as a result of the negative internal pressure produced by the elongation, and the jelly is transformed into a gel (2-phase system). In the elongation of "frozen" rubber, there is a return to the normal form, as occurs when rubber is heated. Rubber contains therefore a sort of network of solid β -component which during elongation of the rubber assumes the form of a bundle of parallel fibers. That these filaments exist is confirmed by the "crystn." expts. of Pummerer and Koch (*C. A.* 18, 3737) and Feuchter (*C. A.* 19, 2576), by the freezing expts. of Hock (*C. A.* 19, 3036) and by microscopic examn. of rubber solns. during evapn. by Bary (*Rev. gén. caoutchouc* 4, No. 31, 7 (1927)). An x-ray diagram is formed only when the β -component is condensed sufficiently, i. e., when the chains of C atoms have only a slight freedom of oscillation. This condition exists when the proportion of β -component is increased by freezing or when it is condensed by elongation. Also in *Kautschuk* 1928, 96-102 but without x-ray diagrams.

Balata rubber. A. D. LUTTRINGER. *Caoutchouc & gutta-percha* 25, 14,036-9, 14,076-9 (1928).—The characteristics of balata and its production in various localities are described.

Power consumption in the preparation of crepe rubber. M. SCHRÖTER AND R. RIZAL. *Med. Profsta. Rubber, Buitenzorg*, 1927, No. 22; *Arch. Rubbercultuur* 11, 397-419 (1927).

Some notes on factory procedure and efficiency, especially in reference to crepe manufacture. T. E. H. O'BRIEN. *Trop. Agr. (Ceylon)* 70, 351-61 (1928).—Formic acid is as satisfactory as acetic acid for coagulating latex. When milky serum is discarded, as is usually done, the value of the rubber lost is frequently greater than that of the acid necessary to coagulate it. Sufficient acid should always be added to produce

a clear or only slightly cloudy serum. The proportion required varies with the individual latex and is not always proportional to its rubber content. Dln. of latex to 2 lb. per gal. provides a coagulum of the right consistency for maceration. *p*-Nitrophenol prevents mold formation on smoked sheet if properly used. If it is added directly to latex in a proportion greater than 1:4000 of rubber, discolored crepe will result. In the proportion mentioned, no discoloration was observed in most tests. However, fungal spots developed when the crepe was subjected to severe tests. Under ordinary conditions of manuf. and storage, it is thought this proportion should prevent spotting.

A. L. MEHRING

Swelling phenomena. The swelling of rubber. P. STAMBERGER. Univ. College London. *Kolloid-Z.* 45, 239-44 (1928); cf. *C. A.* 22, 2078, 3065. When a gel of unmilled pure rubber is removed from a solvent and is placed in the satd. vapor of the solvent, equil. is displaced and the imbibed liquid is exuded. The forces which are responsible for this absorption of part of the solvent are no longer active, and the elastic pressure of the gel walls acts in opposition to these forces, so that the process is reversible. By regarding the exuding action as analogous to a flow of liquid through a capillary, expressions are derived for the forces causing the exudation. The nature of these forces is not explained. The rate of exudation depends upon the temp., solvent and previous history of the gel. The lower the temp., the greater the rate of exudation. The rubber from the gel is less elastic and its behavior toward solvents is no longer the same as before. With solvating solvents like C_6H_6 or $PhMe$, this change is so pronounced that when the liquid is exuded the gel liquefies, and swells in an unstrained way, forming viscous solns. This lends doubt to the existence of 2 phases in rubber. The change in the gel is less marked with solvents of the benzine and Et_2O type. Since the gels are no longer in equil. after removal from their solvent into the satd. vapor, there must be a difference between swelling in liquid and swelling in satd. vapor.

C. C. DAVIS

The destruction of the hydrocarbons of raw rubber by fungi. O. DE VRIES. Rubber Expt. Sta., Breitenzorg, Java. *Centr. Bakt. Parasitenk. II Abt.* 74, 22-4 (1928). Fresh raw rubber contains about 93% hydrocarbons. The loss when infected with fungi may be as much as 22% in 2 years and 30% in 5 years. The viscosity is also markedly decreased.

JOHN T. MYERS

New method of evaluation of the quality of fillers in rubber manufacture. M. PAVLENKO AND P. NAZAROV. *J. Chem. Ind. (Moscow)* 4, 642-50 (1927). Since the quality of rubber products depends not only on their quant. chem. compn., but also on the phys. condition of the components of the colloidal system involved, the question arises, by what analytical method can the latter be detd. Several investigators sought to approach this problem by measurements of the size of the particles of the fillers, and Thies (*C. A.* 20, 310) by detg. the adsorption capacity of fillers toward dyes in aq. soln. The authors propose a different method of detg. the quality of a filler from the point of view of its influence on the strength of the rubber. It is based on the interrelation which exists between the viscosity (internal friction) of a colloidal system consisting of rubber, solvent and filler, the degree of plasticity of the system when devoid of solvent, and finally its degree of elasticity and strength after vulcanization. The viscosity of the system rubber-solvent-filler depends on a number of factors, such as the kind of rubber and its phys. condition, the nature of the filler and the size and shape of its particles, the nature of the solvent, the concn., the duration of interaction and the temp. If the filler is varied and all other conditions are left unchanged, each filler imparts to the system a characteristic viscosity. For the first series of experiments, 5 different brands of C blacks were used as fillers. A large quantity of a 5% rubber soln. in xylene was prepd. and portions of this soln. were taken for each subsequent expt., which consisted in stirring 25 g. of a particular brand of C black with 500 cc. of the rubber soln., pouring the mixt. in a glass cylinder 26 cm. long and 26 mm. in diam., placing it in a thermostat at 25° and measuring its relative viscosity at regular intervals. Viscosity measurements were made by detg. the time (in sec.) required by a glass ball 6 mm. in diam. to drop from the surface of the viscous mass to the bottom, and dividing this figure by the time required in a blank test for the ball to pass through an equal layer of the rubber soln. contg. no C black. The ratio obtained was the relative viscosity of the system rubber-xylene-C black. It was found that the viscosity of the blank soln. did not appreciably change in the course of time, whereas that of the system containing C black underwent considerable changes. These changes enabled the authors to draw a curve of relative viscosity as a function of time for every particular C black. During the first 24 hrs. the viscosity gradually increased, until the curve reached a max. and after a certain turning point it began to drop. Each particular

brand of C black gave a characteristic curve. Presumably the initial increase in viscosity depends upon the fact that a uniform mixt. of C black with rubber soln. is not attained at once, the mixt. being at first flocculent in spite of being stirred with a glass rod; the flocculency gradually decreases and, by the time it almost disappears, the max. relative viscosity is reached, after which the curve begins to drop, due to disintegration of the rubber. Expts. confirmed the theoretical considerations, according to which the C black brands which produced the highest relative viscosity (at the turning point) in rubber solns. gave the strongest vulcanizates, as seen in the following table:

C Black brand	Relative viscosities at turning points	Strength in kg./cm. ² of vulcanizates
Microne	2.54	225.4
G. E. T. No. 3	2.36	209.7
G. E. T. No. 5	2.10	195.6
Dutch	1.95	188.1
Dure	1.72	173.8

It is remarkable that the better the brand of C black, the longer its mixt. with rubber soln. remained flocculent. This observation alone can be used as a fairly reliable guide in detg. the value of a given filler, but relative viscosity detns. give surer results. In expts. carried out in the same manner with various brands of kaolins and of chalks as fillers instead of C black, the results were about the same. BERNARD NELSON

C black (HOPKINS, BACKUS) 18. C black (U. S. pat. 1,681,945) 18. Catalytic dehydrogenation of hydrocarbons [use in manufacture of rubber] (Brit. pat. 283,105) 22.

Rubber. J. C. PETERSON. Brit. 283,122, Jan. 3, 1927. In the manuf. of sheet material with layers of vulcanized and unvulcanized rubber, the unvulcanized layer has incorporated in it a neutralizer of vulcanizing agents such as small quantities of HCl, H₂SO₄, or H₃PO₄ to prevent partial vulcanization of this layer due to migration of the vulcanizing agents. Examples and formulas are given. Cf. C. A. 21, 3490.

Rubber. TOKYO GOMU KABUSHIKI KAISHA. Fr. 634,628, May 18, 1927. A rubber which will float on water and is resistant to oils is made by mixing factis, S, alkali soap and diphenylguanidine with the crude rubber instead of the usual mineral solids.

Porous rubber. FERDINAND RINGER. Fr. 634,694, May 19, 1927. Metallic carbonates or bicarbonates are added to rubber before vulcanization so that the liberation of gas during vulcanization causes a swelling of the rubber.

Rubber solutions. J. V. JOHNSON. Brit. 282,617, June 10, 1926. In prep. rubber solns. which also may contain nitrocellulose, coloring substances, etc., there is used as solvent the oily product obtained by the catalytic hydrogenation of oxides of C by processes such as described in Brit. 227,147 (C. A. 19, 2673), Brit. 229,714 (C. A. 19, 3093), Brit. 237,030 (C. A. 20, 1414) and Brit. 238,319 (C. A. 20, 1995) or a fraction of such a product or the product of hydrogenation, esterification or condensation of such products or fractions. Solns suitable for use as lacquers may be thus prep.

Isomerizing rubber. H. L. FISHER (to R. F. Goodrich Co.). Brit. 282,778, Dec. 28, 1926. Thermoplastic products are obtained by heating rubber with a phenol and a third substance which may be chlorinated rubber, rubber hydrochloride, diphenylamine S chloride, chlorinated rubber hydrochloride, pinene hydrochloride, diphenylamine hydrochloride, trichloroaniline hydrochloride, *m*-nitroaniline hydrochloride, HgCl₂, SnCl₄, naphthalene tetrachloride, triphenyl chloromethane, ZnBr₂, rubber dibromide, diphenylamine hydrobromide, CaSO₄, Al₂(SO₄)₃, HgSO₄, diphenylamine sulfate or diphenylamine trichloroacetate. The materials may be heated for 20 hrs. at 134–160°.

Coating metals with rubber. R. M. WITHCOMBE. Brit. 282,737, Dec. 30, 1926. A soln. of rubber contg. S is applied to metal surfaces, the solvent is allowed to evaporate and the surface is subjected to dry heated air (suitably at a temp. of about 110–130°). The soln. may also contain oxides, pigments and accelerators.

Direct production of rubber goods from rubber dispersions. PAUL KLEIN and ALBERT HEALBY (to American Anode Incorporated). U. S. 1,683,588, Sept. 4. The degree of coagulation is regulated by adding soft soap to natural latex in the proportion of 6–12 g. soft soap to 1 l. of latex and the latex is deposited by electrophoresis upon an anodic mold.

Curing rubber tubes upon a mandrel. DANIEL E. HENNESSY (to Fisk Rubber Co.). U. S. 1,682,124, Aug. 28. A film of cement is interposed between the ends of the tube and the mandrel during vulcanization, to avoid need of binding to prevent blowing. U. S. 1,682,125 specifies heating the end portions of the tube to soften the rubber preparatory to vulcanization, and clamping the end portions to the mandrel.

Composition for filling tires. A. E. MILLS and W. T. GALBRAITH. Brit. 283,249, Sept. 25, 1926. A compn. formed of ground burnt cork 5, glue 3.5, linseed and castor oil 1, rubber latex 0.5 and "cellulose derivs." 0.25 part is mixed with 2-4% NaOH, about 2% oxide of Mn or Pb or $ZnCl_2$ and 2% of chrome alum, and steam is blown through the materials for 5-10 hrs. Turpentine 2% is added and heated air is passed through the mass for 4-12 days after which it is rolled and molded.

Rubber flooring material. CHAUNCEY C. LOOMIS (to Latex Products, Inc.). U. S. 1,682,530, Aug. 28. A flooring comprises a dried non-vulcanized rubber latex and asbestos, clay, wood, cork or other suitable filler; a large proportion of the rubber content may be adjacent the upper surface of the material.

Accelerators for rubber vulcanization. L. B. SEHRELL and J. TERPPEMA. Brit. 282,947, Nov. 9, 1926. Mercaptothiazoles are made by reducing *o*-nitrohalogenaryl compds. with a sol. basic hydrosulfide in the presence of CS_2 and H_2S ; e. g., 2-mercaptobenzothiazole is made by suspending *o*-nitrochlorobenzene in an aq. soln. of Na sulfide satd. with H_2S , warming and passing H_2S and CS_2 through the mixt.

Accelerators for rubber vulcanization. WM. P. TER HORST (to Rubber Service Laboratories Co.). U. S. 1,682,728, Aug. 28. The reaction product of piperidine-pentamethylene dithiocarbamate with dithiazyl trithiocarbonate or a similar compd. is used as an accelerator. U. S. 1,682,729 specifies the use of the reaction product of piperidine with dithiazyltrithiocarbonate or similar products.

Substituted thiuram polysulfides. GEORGE S. WHITBY (to Roessler & Hasslacher Chemical Co.). U. S. 1,681,717, Aug. 21. The products formed by treating the salts of substituted dithiocarbamic acids with S_2Cl_2 or SCl_2 may be used as accelerators in the vulcanization of rubber. Examples are given of the prepn. of diphenylethylthiuram tetrasulfide, diphenylethylthiuram trisulfide and diphenylmethylthiuram tetrasulfide, which may be formed from the corresponding Na or NH₄ phenylalkyldithiocarbamates.

Vulcanizing rubber. RALPH V. HEUSER (to Albert C. Burrage, Jr.). U. S. 1,681,806, Aug. 21. An *o*-tolylguanidine such as tritolylguanidine is used as an accelerator. Cf. C. A. 21, 2856, 3318.

Vulcanizing rubber. I. G. FARBENIND. A.-G. Brit. 282,892, Sept. 30, 1926. Formamide is used as an accelerator.

Vulcanized rubber compositions. PHILIP SCHRIDROWITZ (to Vultex Ltd.). U. S. 1,682,857, Sept. 4. Vulcanization of compns. contg. uncoagulated rubber is effected, e. g., by use of Na polysulfide and an accelerator, at a temp. below the temps. ordinarily employed in hot vulcanizing methods and under such conditions as to prevent any substantial coagulation of the rubber during the vulcanization.

Compounds resembling rubber. I. G. FARBENIND. A.-G. Fr. 634,857, May 23, 1927. The products coming from the hydrogenation under pressure of mineral oils, coal and other carboniferous substances are dehydrogenated and (or) dissocd. to give unsatd. compds. and then polymerized. The polymerization may be replaced by a fixation on the compds. of other elements or compds. such as halogens, hydrohalogen acids, hypohalogenous acids or HCN. The dehydrogenation or the dissocn. may be accomplished in several steps.
